

# Digital Signal Processing

Analog-to-Digital Converter (ADC) converts an input analog value to an output digital representation.

This digital data is processed by a microprocessor and output to a Digital-to-Analog Converter (DAC) the converts an input binary value to an output voltage.

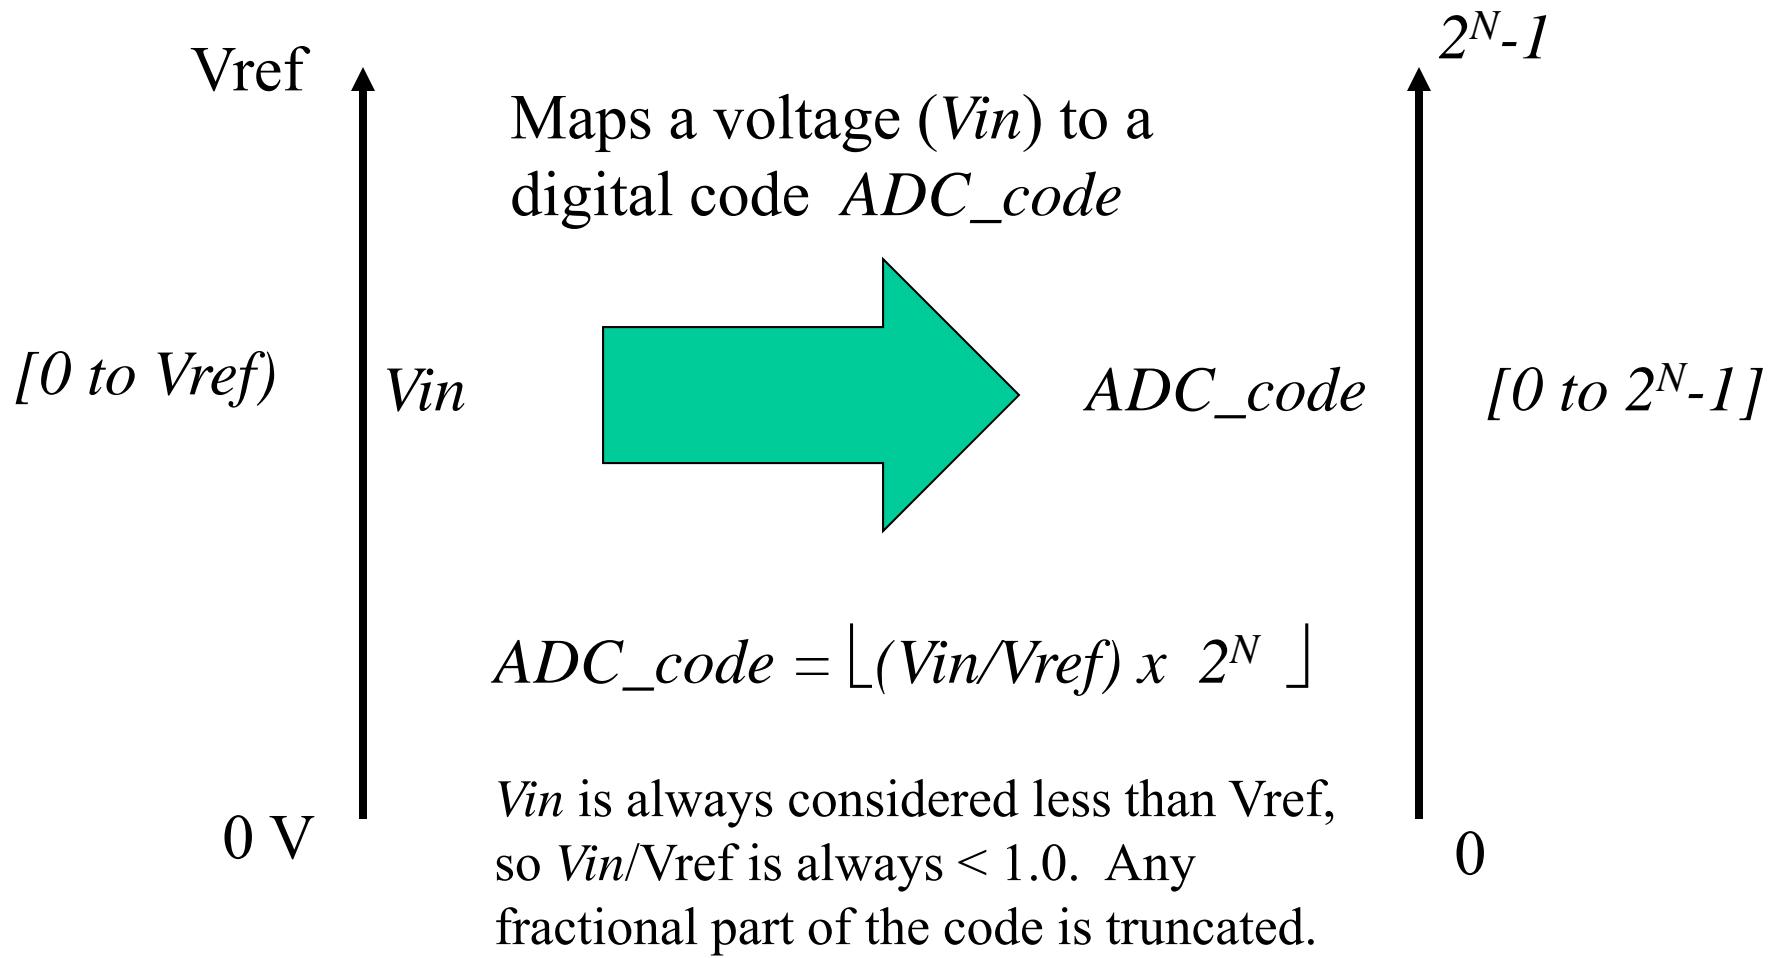

# Applications

- Audio
  - Speech recognition
  - special effects (reverb, noise cancellation, etc)
- Video
  - Filtering
  - Special effects
  - Compression
- Data logging

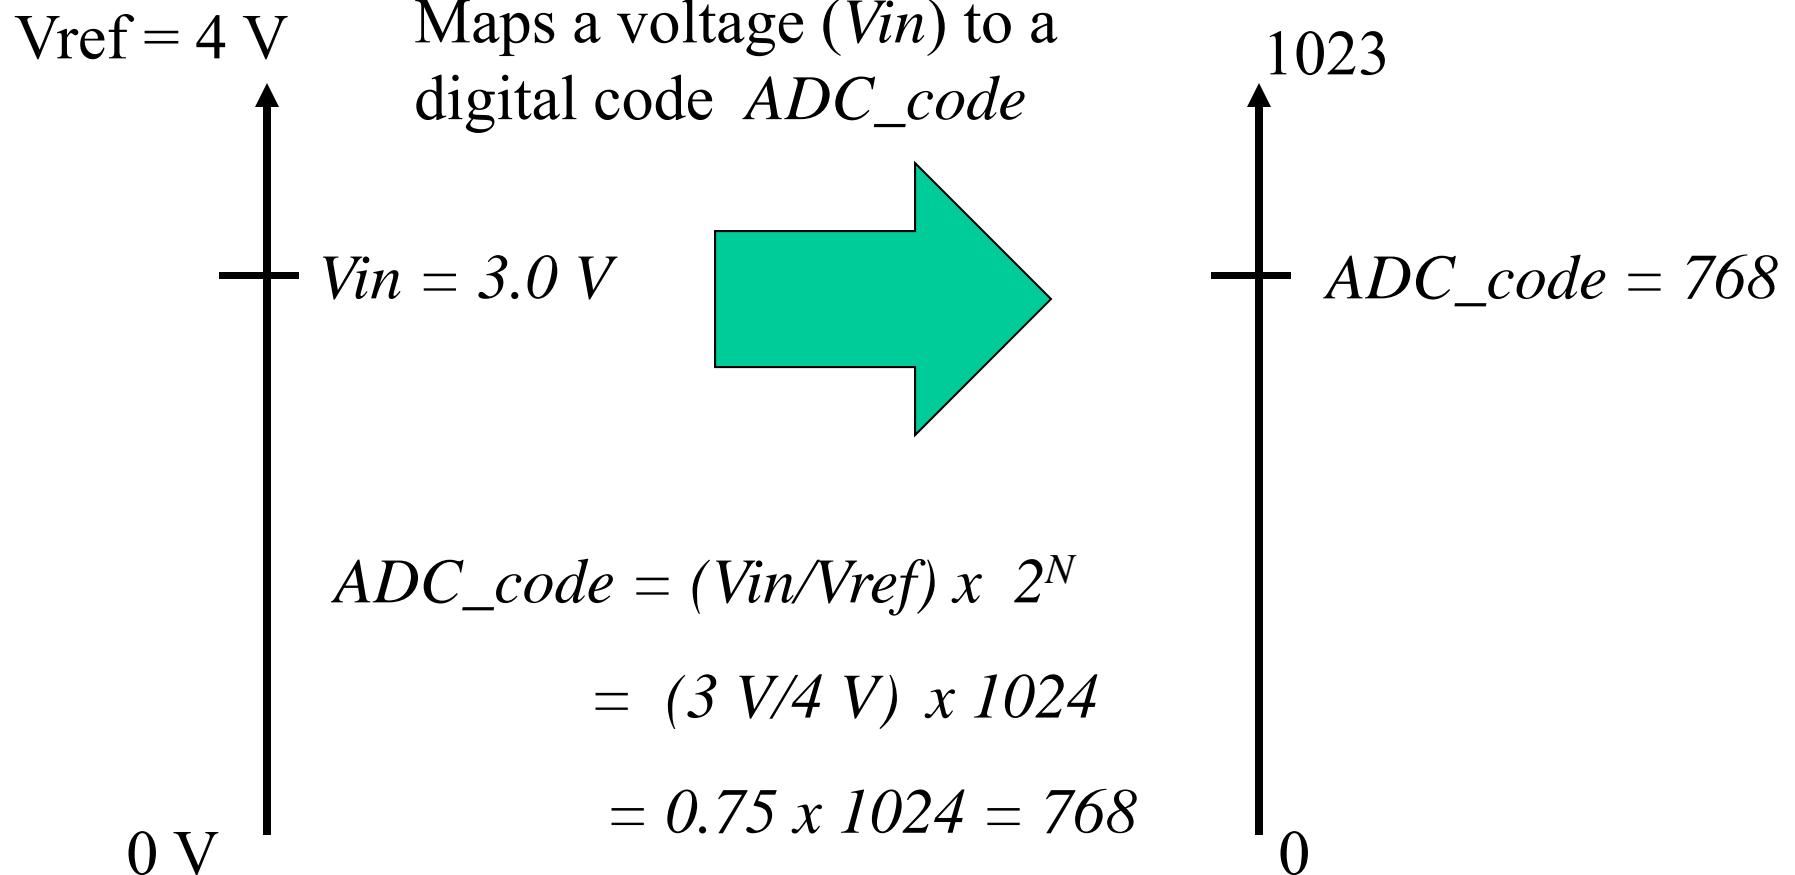

# Vocabulary

- ADC (Analog-to-Digital Converter) – converts an analog signal (voltage/current) to a digital code
- DAC (Digital-to-Analog Converter) – converts a digital code to an analog value (voltage/current)
- Sample period – for ADC, time between each conversion
  - Typically, samples are taken at a fixed rate
- Vref (Reference Voltage) – analog signal varies between 0 and Vref, or between +/- Vref
- Resolution – number of bits used for conversion (8 bits, 10 bits, 12 bits, 16 bits, etc).
- Conversion Time – the time it takes for an analog-to-digital conversion

# An N-bit ADC

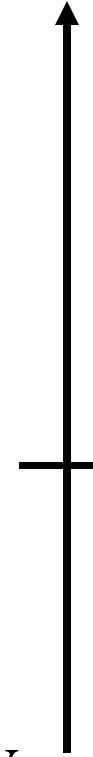

# Example: A 10-bit ADC

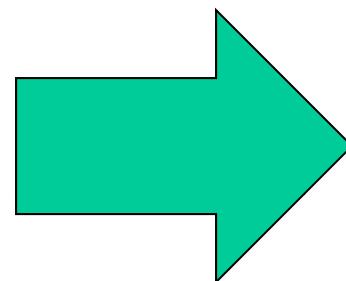

## Example: A 10-bit ADC

$V_{ref} = 4 \text{ V}$

Maps a voltage ( $V_{in}$ ) to a digital code  $ADC\_code$

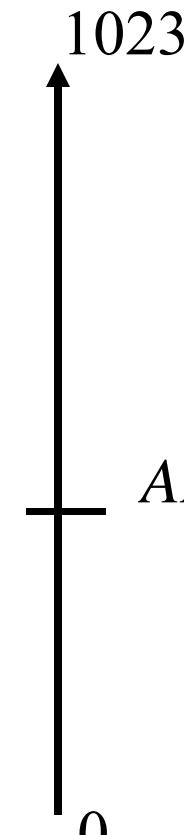

$V_{in} = 2.17 \text{ V}$

$$ADC\_code = (V_{in}/V_{ref}) \times 2^N$$

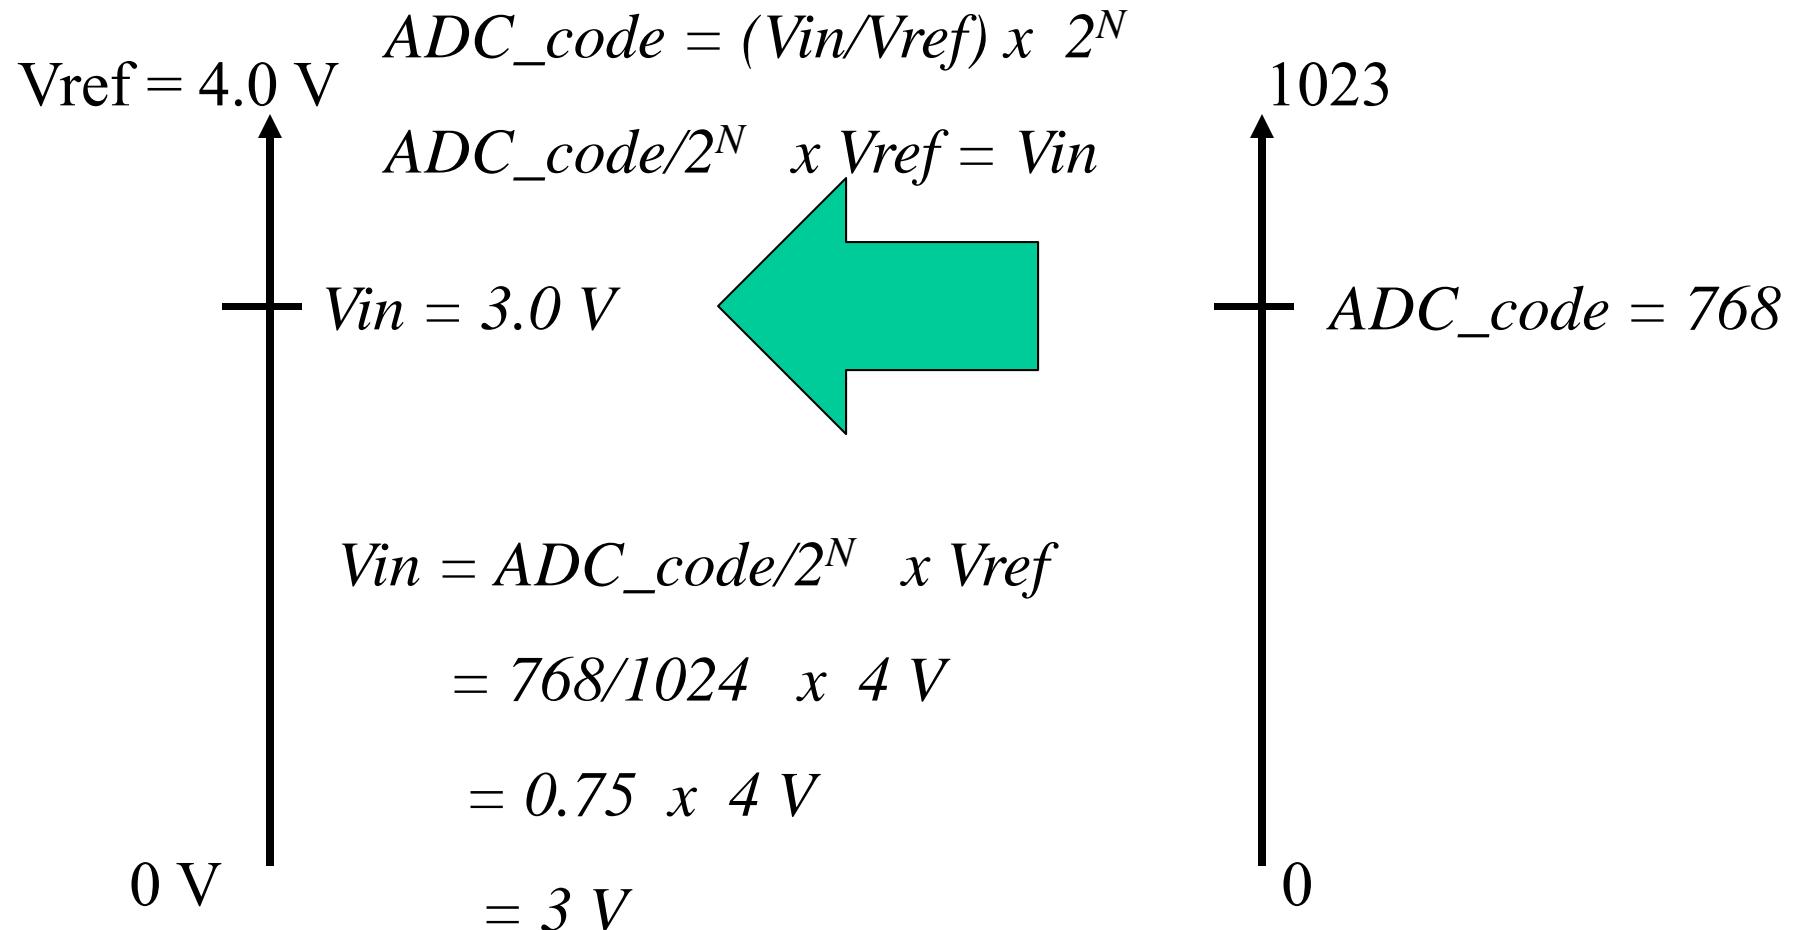

$$= (2.17 \text{ V}/4 \text{ V}) \times 1024$$

$$= 555.52 = 555$$

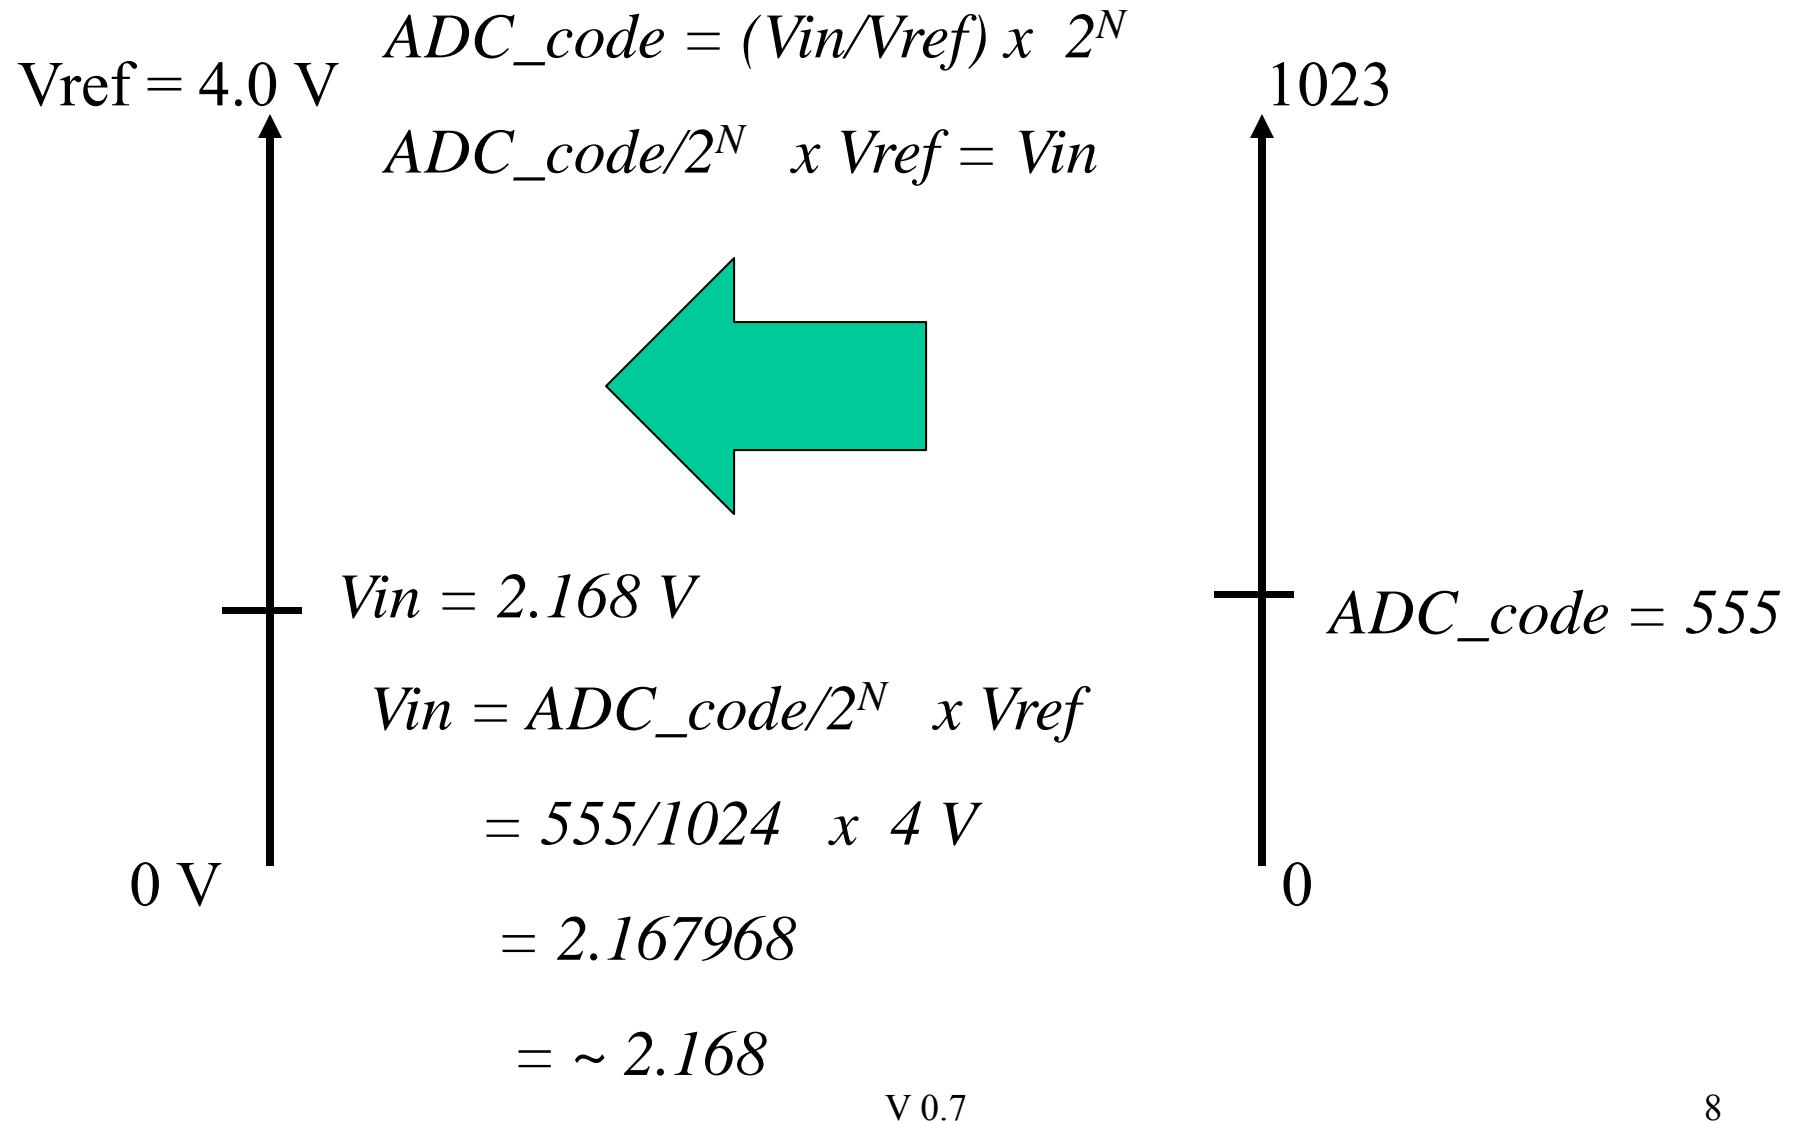

$ADC\_code = 555$

# Going from Code to Voltage

# Going from Code to Voltage

# ADC Resolution

For an N-bit ADC, the smallest input voltage that can be resolved is 1 LSb, or:

$$1/2^N * (V_{ref+} - V_{ref-})$$

Where  $V_{ref+}$  is the positive reference voltage and  $V_{ref-}$  is the negative reference voltage.

We will use  $V_{ref-} = 0$  V, and refer to  $V_{ref+}$  as simply  $V_{ref}$ , so this simplifies to

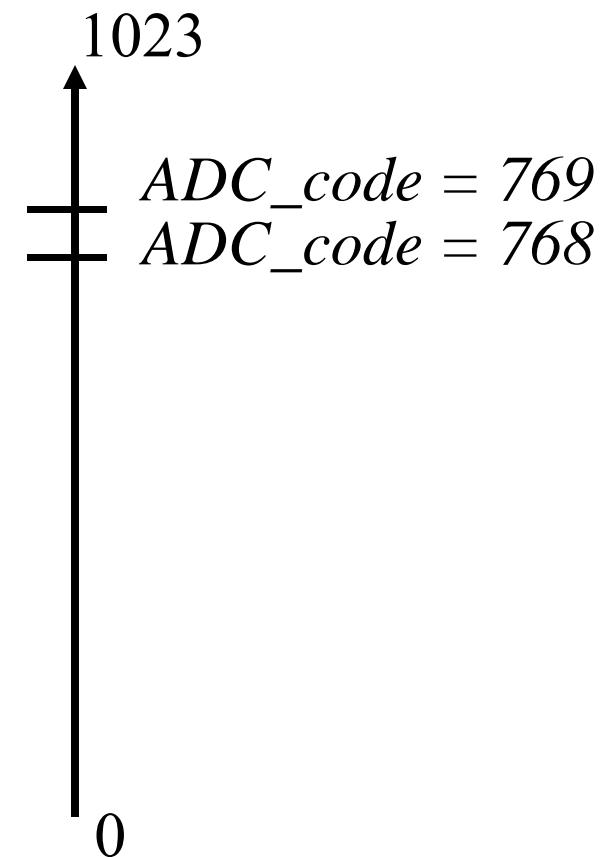

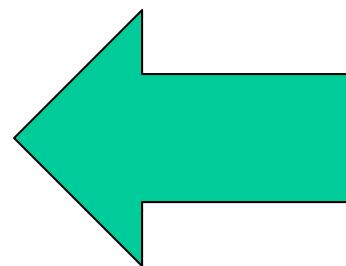

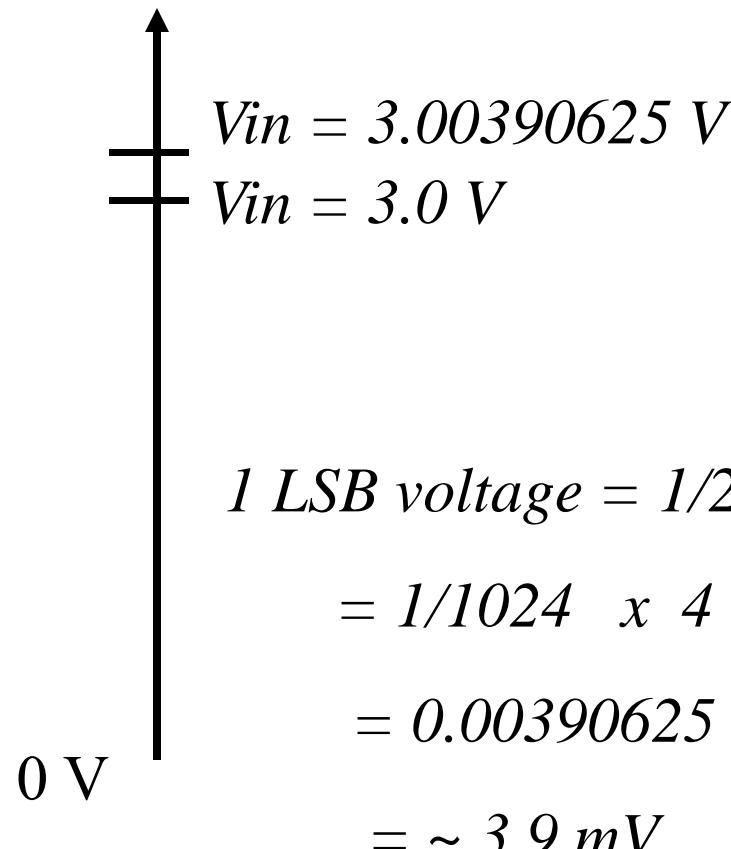

$$1/2^N * V_{ref}.$$

For  $V_{ref} = 4$  V, and  $N = 4$ , what is 1 LSb?

$$1/2^4 * 4 \text{ V} = 1/16 * 4 \text{ V} = 0.25 \text{ V.}$$

# Example: 10-bit ADC Resolution

$V_{ref} = 4.0 \text{ V}$

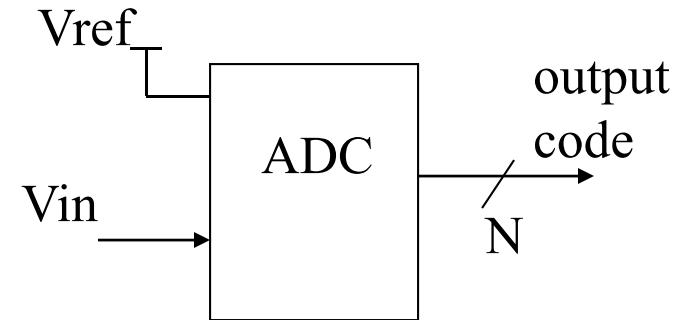

# ADC, DAC Equations

ADC:  $V_{in}$  = input voltage,  $V_{ref+}$  = reference voltage,  $V_{ref-} = 0$  V.  
 $N$  = number of bits of precision

$$V_{in}/V_{ref} * 2^N = \text{output\_code}$$
$$\text{output\_code}/2^N * V_{ref} = V_{in}$$

$$1 \text{ LSB} = V_{ref}/2^N$$

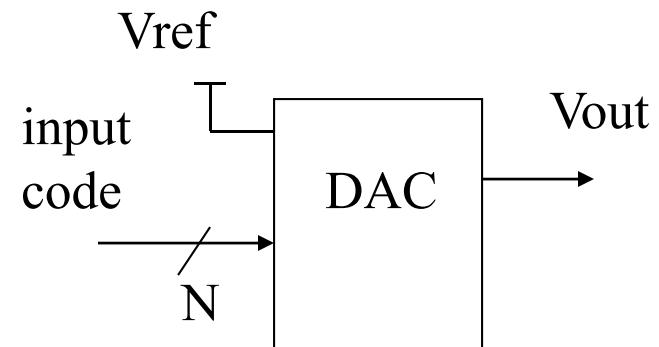

---

DAC:  $V_{out}$  = output voltage,  $V_{ref}$  = reference voltage,  
 $N$  = number of bits of precision

$$V_{out}/V_{ref} * 2^N = \text{input\_code}$$
$$\text{input\_code}/2^N * V_{ref} = V_{out}$$

$$1 \text{ LSB} = V_{ref}/2^N$$

# Sample ADC, DAC Computations

If  $V_{ref} = 5V$ , and a 10-bit A/D output code is 0x12A, what is the ADC input voltage?

$$\begin{aligned} V_{in} &= \text{output\_code}/2^N * V_{ref} = (0x12A)/2^{10} * 5 \text{ V} \\ &= 298/1024 * 5 \text{ V} = 1.46 \text{ V (ADC } V_{in}) \end{aligned}$$

---

If  $V_{ref} = 5V$ , and an 8-bit DAC input code is 0xA9, what is the DAC output voltage?

$$\begin{aligned} V_{out} &= \text{input\_code}/2^N * V_{ref} = (0xA9)/2^8 * 5 \text{ V} \\ &= 169/256 * 5 \text{ V} = 3.3 \text{ V (DAC } V_{out}) \end{aligned}$$

---

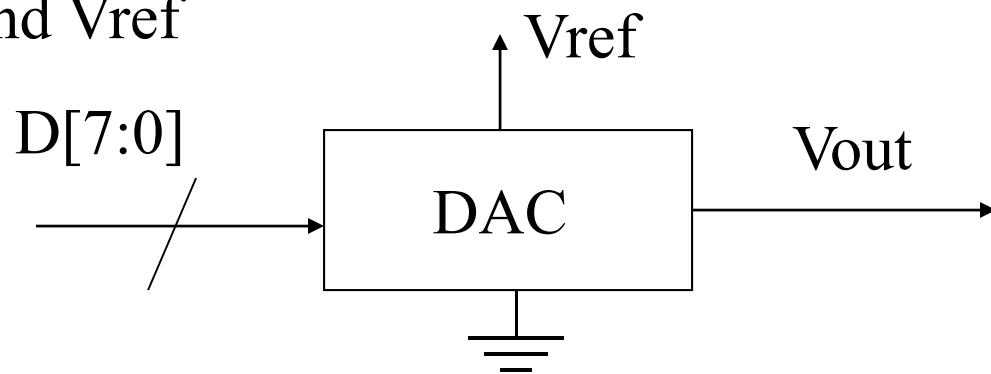

If  $V_{ref} = 4V$ , and an 8-bit A/D input voltage is 2.35 V, what is the ADC output code?

$$\begin{aligned} \text{output code} &= V_{in}/ V_{ref} * 2^N = 2.35 \text{ V} / 4 \text{ V} * 2^8 \\ &= .5875 * 256 = 150.4 = 150 = 0x96 \text{ (ADC output code)} \end{aligned}$$

---

# Digital-to-Analog Conversion

For a particular binary code, output a voltage between 0 and Vref

Assume a DAC that uses an unsigned binary input code, with  $0 \leq V_{out} < V_{ref}$ . Then

$$D = 0000\ 0000 \quad V_{out} = 0V$$

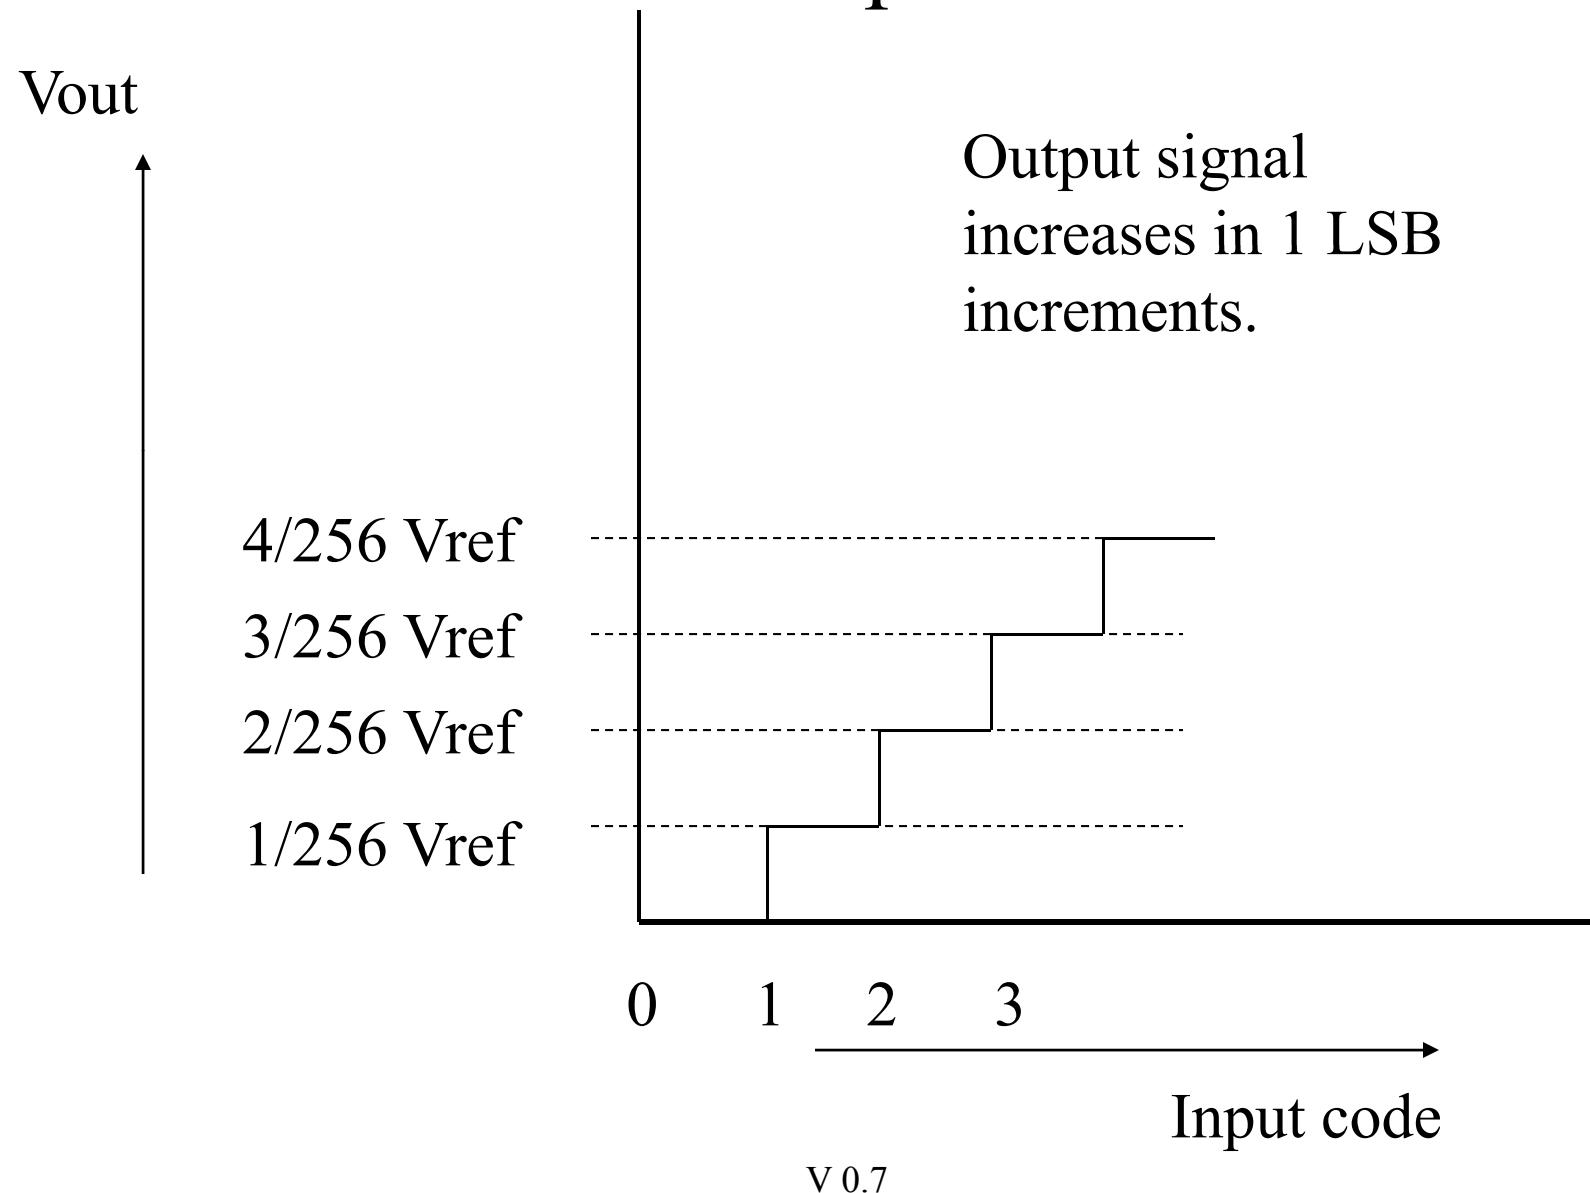

$$D = 0000\ 0001 \quad V_{out} = V_{ref}(1/256) \quad (\text{one LSB})$$

$$D = 0000\ 0010 \quad V_{out} = V_{ref}(2/256)$$

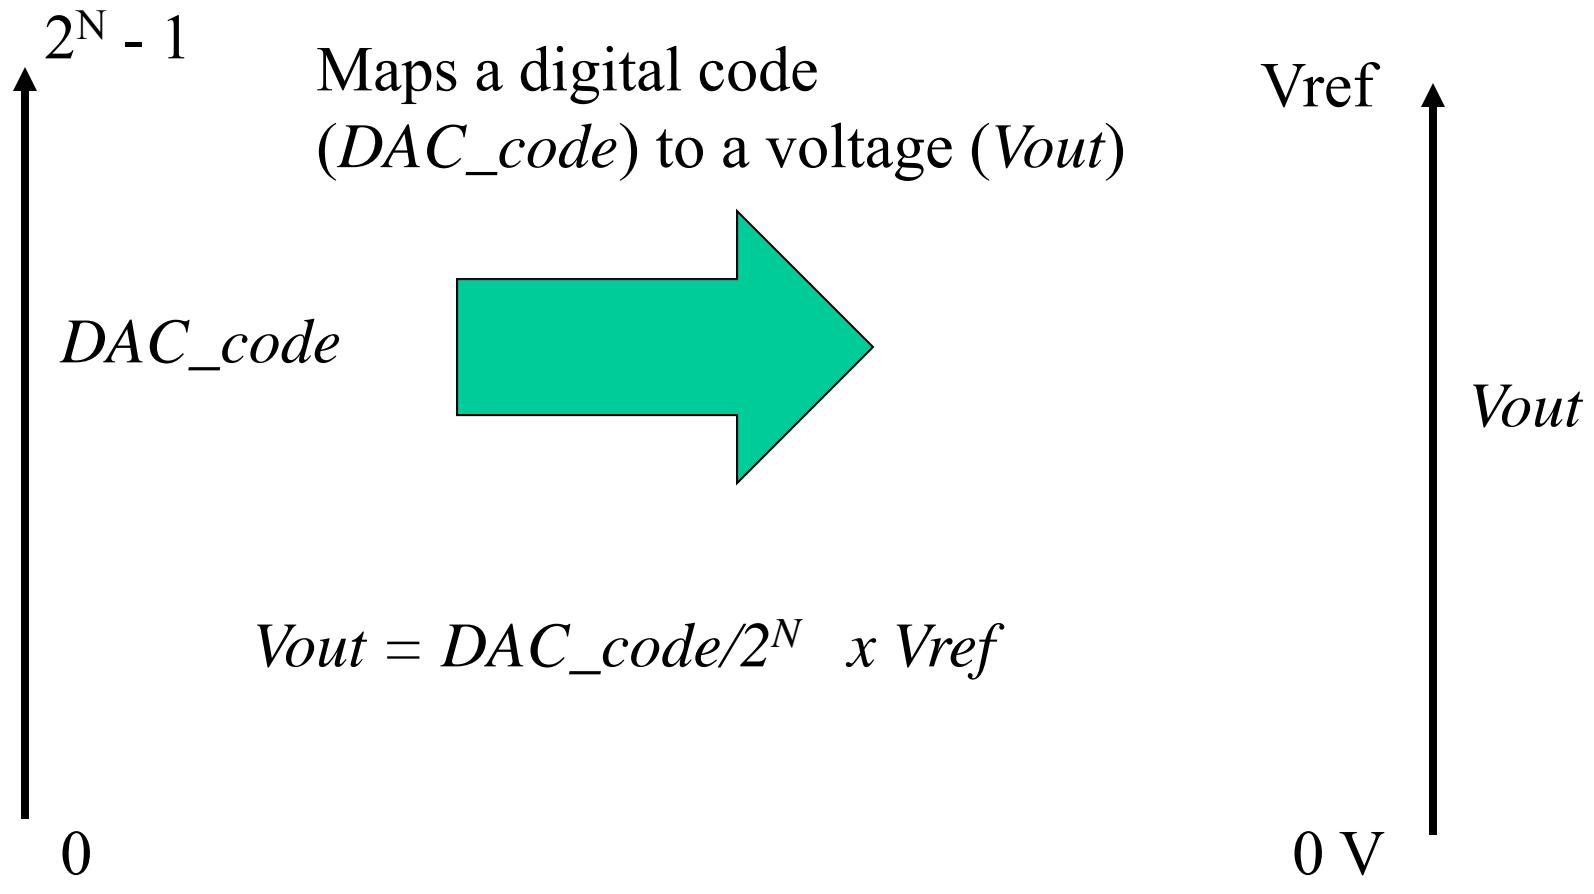

...

$$D = 1111\ 1111 \quad V_{out} = V_{ref}(255/256) \quad (\text{full scale})$$

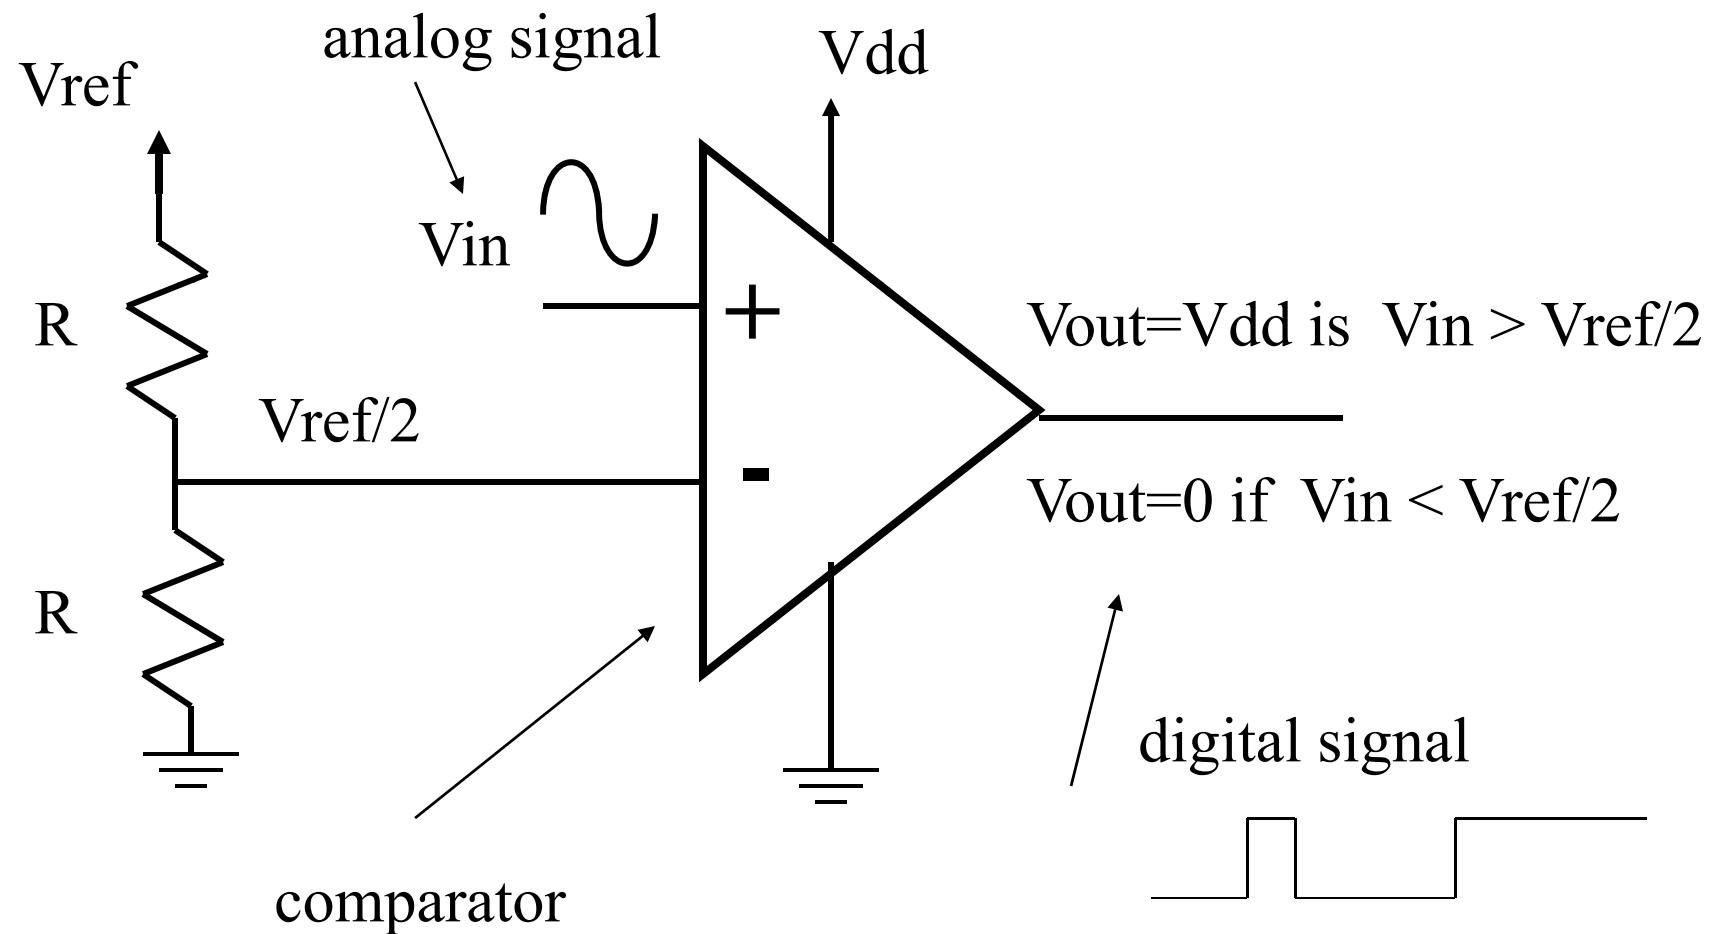

# DAC Output Plot

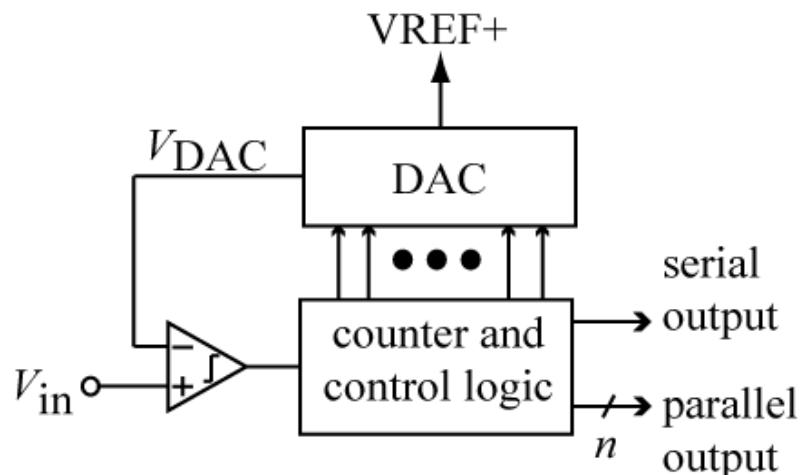

# An N-bit DAC

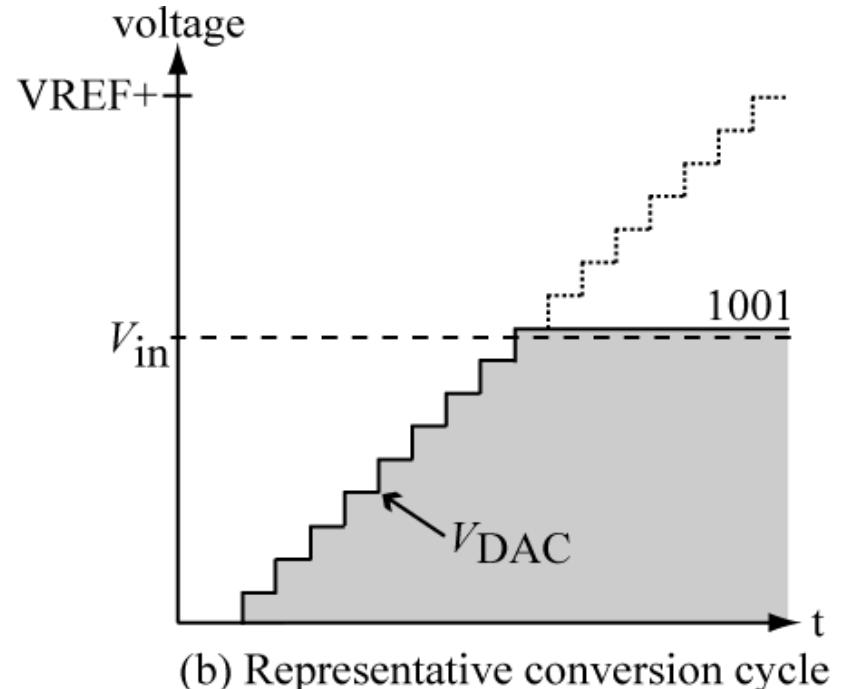

# A 1-bit ADC

# Counter Ramp ADC

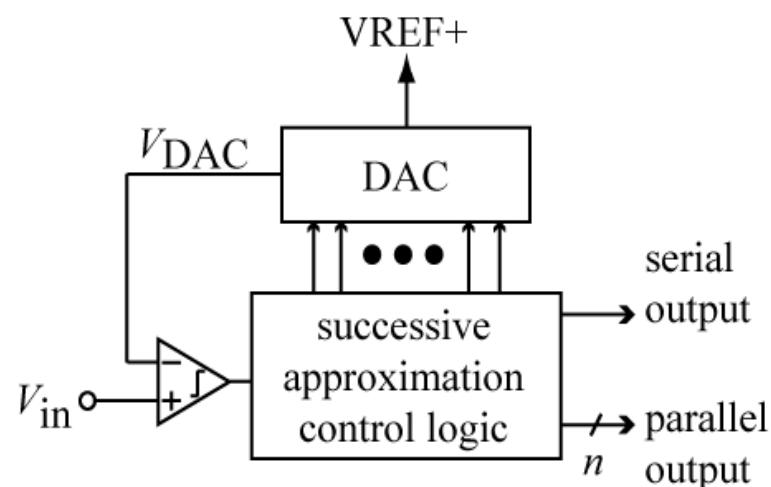

(a) Structure

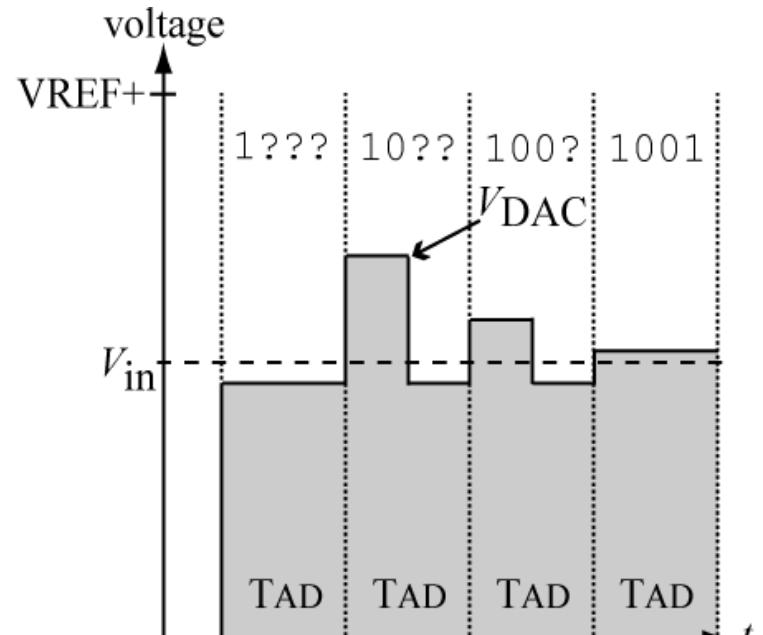

(b) Representative conversion cycle

Control logic use a counter to apply successive codes 0,1,2,3,4... to DAC (Digital-to-Analog Converter) until DAC output is greater than  $V_{in}$ . This is SLOW, and have to allocate the worst case time for each conversion, which is  $2^N$  clock cycles for an  $N$ -bit ADC.

# Successive Approximation ADC

(a) Structure

(b) Representative conversion cycle

Initially set VDAC to  $\frac{1}{2}$  Vref, then see if Vin higher or lower than VDAC. If  $> \frac{1}{2}$  Vref, then next guess is between Vref and  $\frac{1}{2}$  Vref, else next guess is between  $\frac{1}{2}$  Vref and GND. Do this for each bit of the ADC. Takes N clock cycles.

# Successive Approximation Example

Given a 4-bit Successive Approximation ADC, and  $V_{ref} = 4 \text{ V}$ .

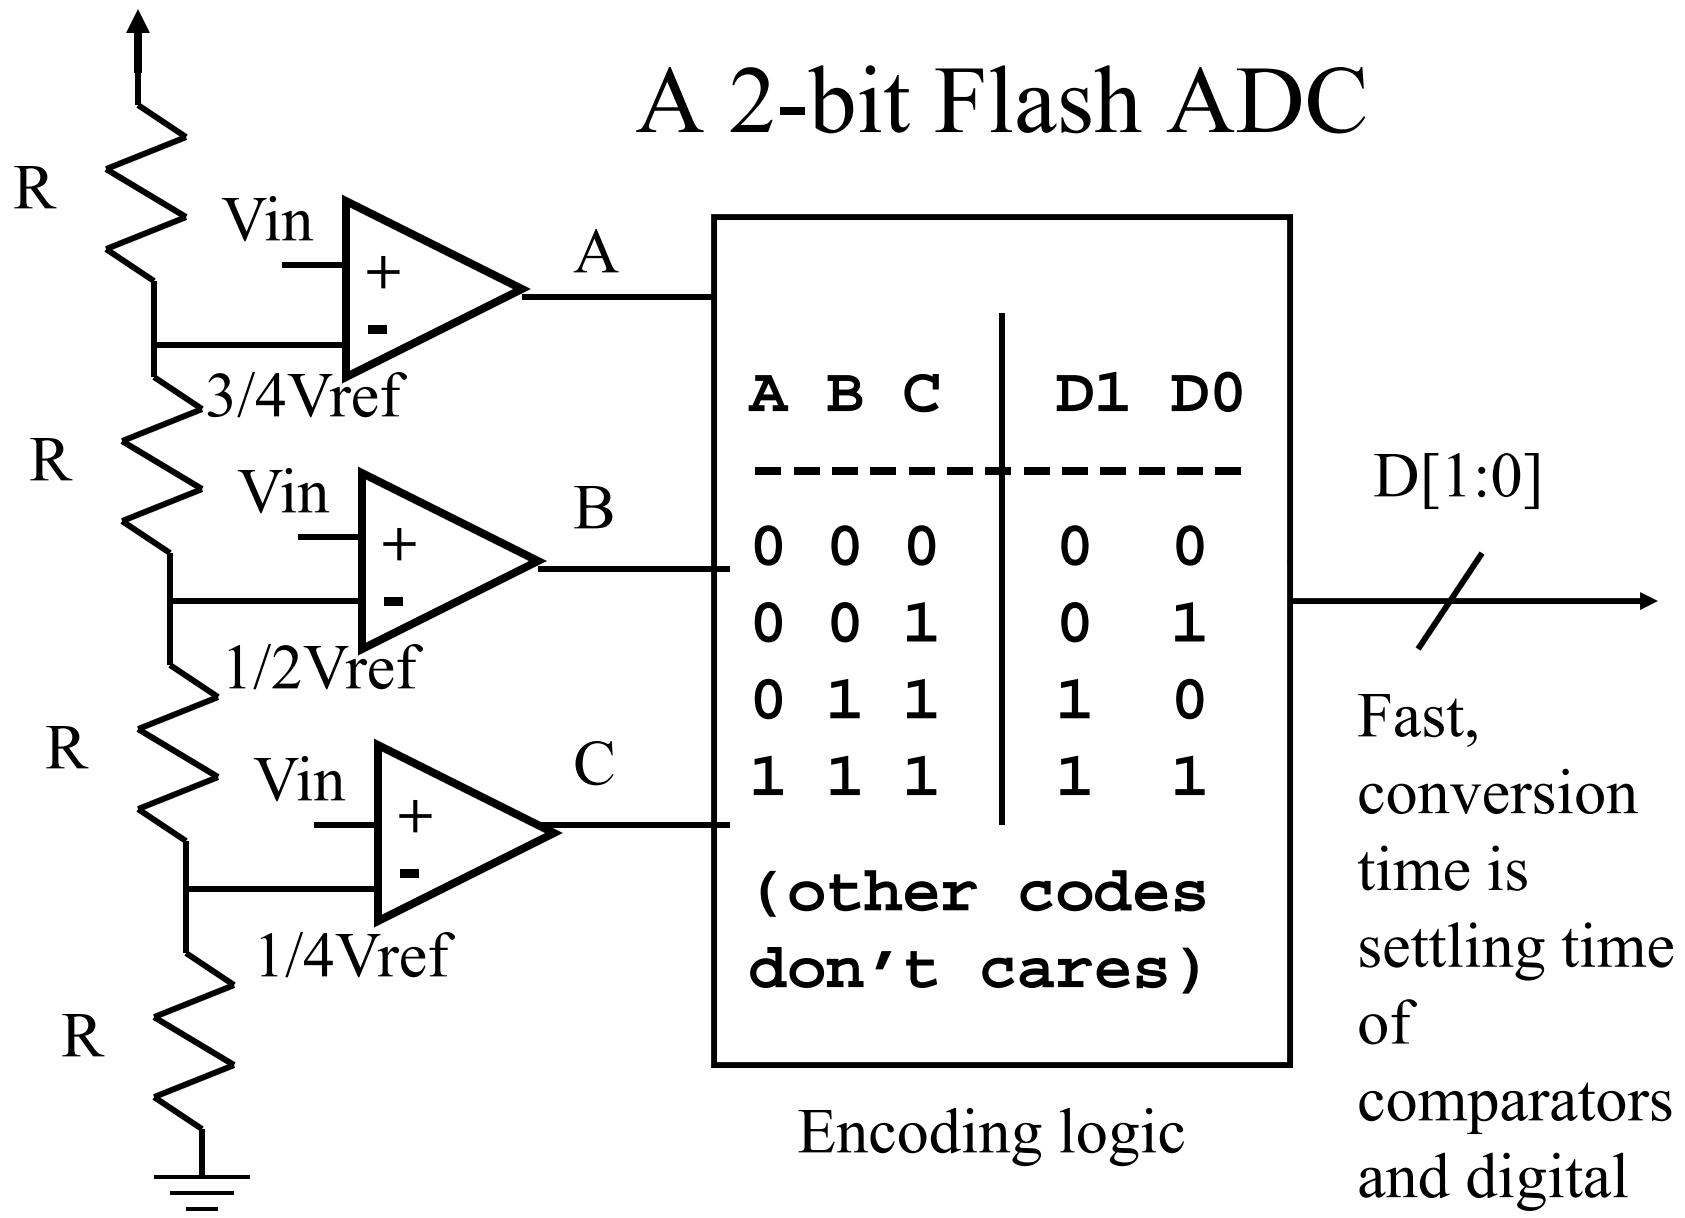

Let  $V_{in} = 3.14159 \text{ V}$ . Clear DAC input to 0b0000.

1. First guess, DAC input = 0b1000 = 8, so  $V_{dac} = 8/2^4 * 4 \text{ V} = 8/16 * 4 \text{ V} = 2 \text{ V}$ .  
 $V_{dac} (2 \text{ V}) < V_{in} (3.14159 \text{ V})$ , so guess of ‘1’ for MSb of DAC was correct.
2. Set next bit of DAC to ‘1’, DAC input = 0b1100 = 12, so  $V_{dac} = 12/16 * 4 = 3 \text{ V}$ .  
 $V_{dac} (3 \text{ V}) < V_{in} (3.14159 \text{ V})$ , so guess of ‘1’ for bit2 of DAC was correct.
3. Set next bit of DAC to ‘1’, DAC input = 0b1110 = 14, so  $V_{dac} = 14/16 * 4 = 3.5 \text{ V}$ .  
 $V_{dac} (3.5 \text{ V}) > V_{in} (3.14159 \text{ V})$ , so guess of ‘0’ for bit1 of DAC was incorrect.  
Reset this bit to ‘0’.
4. Set last bit of DAC to ‘1’, DAC input = 0b1101 = 13, so  $V_{dac} = 13/16 * 4 = 3.25 \text{ V}$ .  
 $V_{dac} (3.25 \text{ V}) > V_{in} (3.14159 \text{ V})$ , so guess of ‘0’ for bit0 of DAC was incorrect.  
Reset this bit to ‘0’.

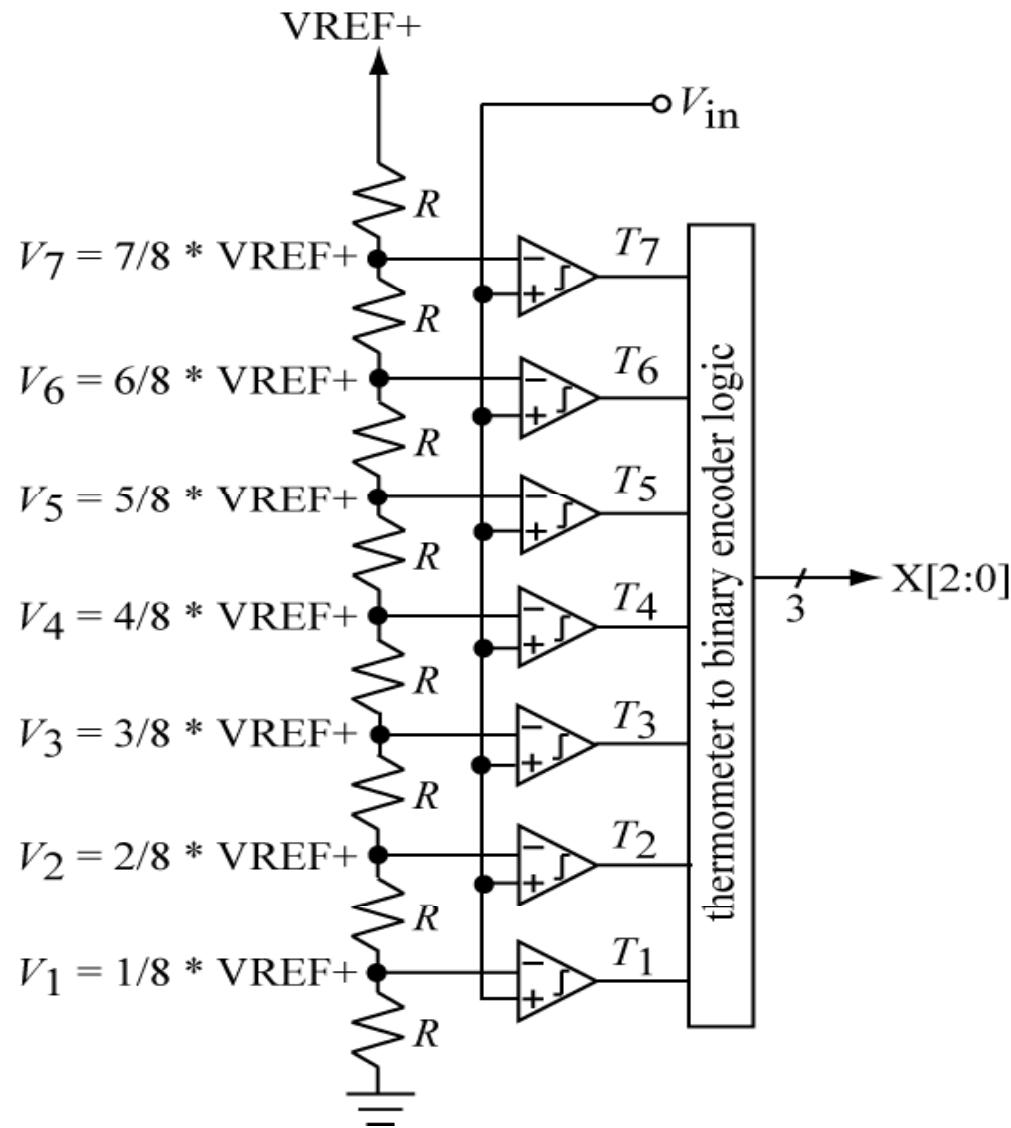

Final ADC output code is 0b1100.

Check result: output code =  $V_{in}/V_{ref} * 2^N = 3.14159/4 * 16 = 12.57 = 12$  (truncated).

# A 2-bit Flash ADC

# 3-bit Flash ADC

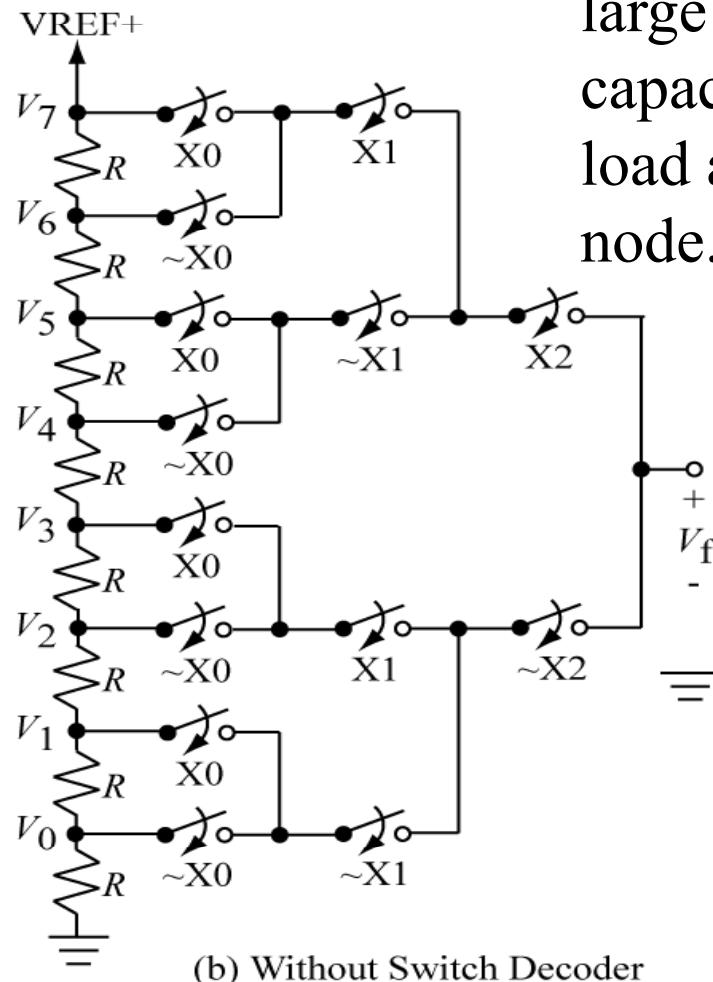

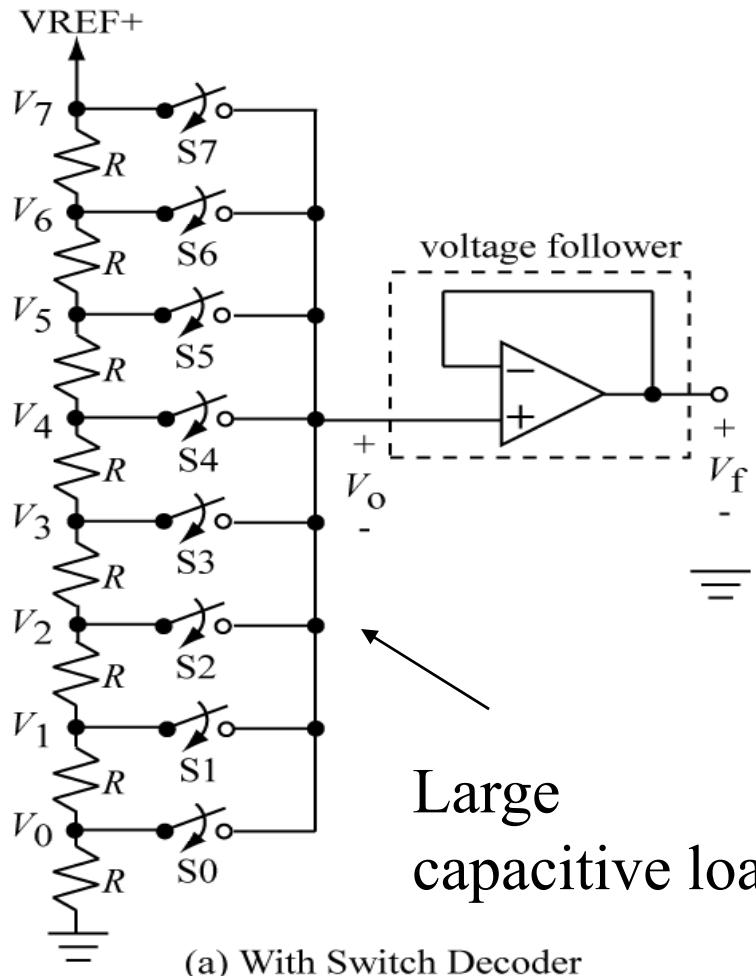

# ADC Architecture Summary

- *Flash* ADCs
  - Fastest possible conversion time
  - Requires the most transistors of any architecture
  - N-bit converter requires  $2^N - 1$  comparators.
  - Commercially available flash converters up to 12 bits.
  - Conversion done in one clock cycle
- *Successive approximation* ADCs
  - Use only one comparator
  - Take one clock cycle per bit
  - High precision (16-bit converters are available)

# Commercial ADCs

- Key timing parameter is *conversion time* – how long does it take to produce a digital output once a conversion is started
- Up to 16-bit ADCs available
- Separated into fast/medium/low speed families
  - Serial interfaces common on medium/low speed ADCs
- For high-precision ADCs, challenge is keeping system noise from affecting conversion
  - Assume a 16-bit DAC, and a 4.1V reference, then  $1 \text{ LSB} = 4.1/2^{16} = 62 \mu\text{V}$ .

# Flash DAC

Eliminates  
large  
capacitive  
load at one  
node.

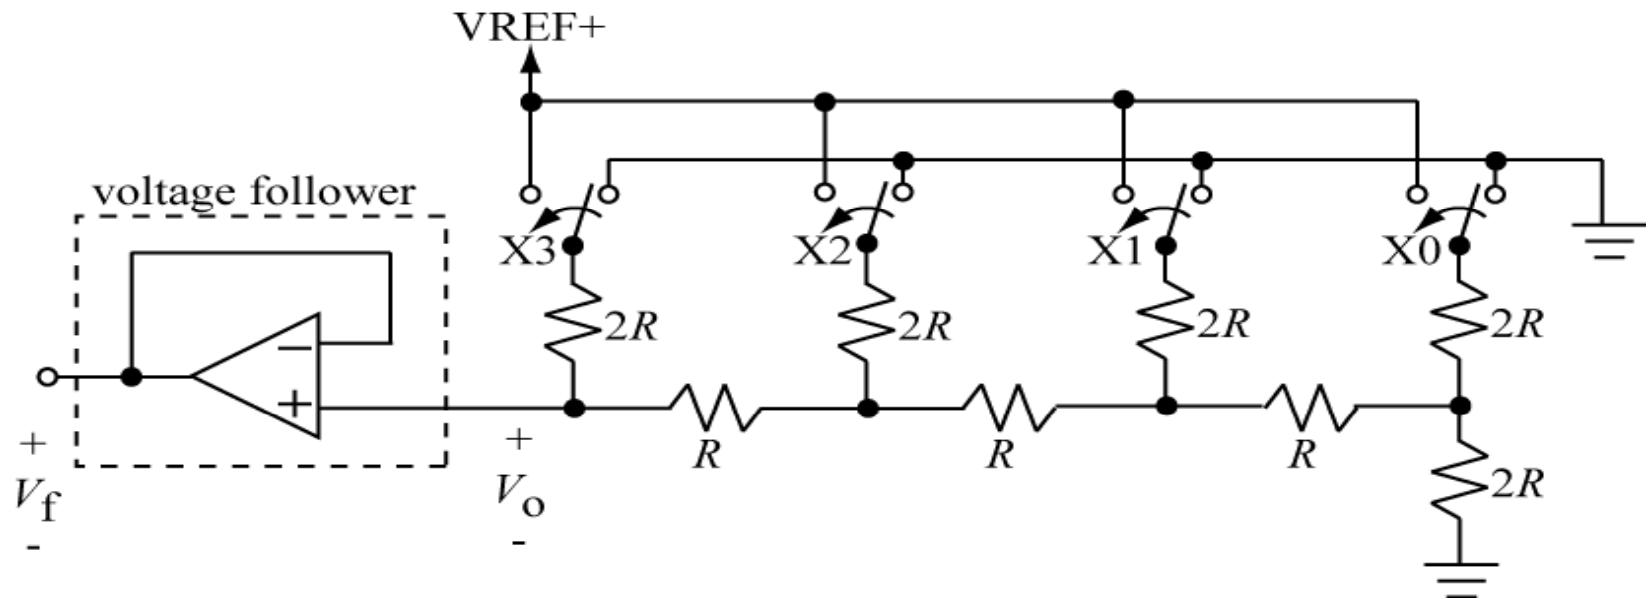

N-bit DAC requires  $2^N$  resistors!

# R-2R Ladder DAC

Resistor ladder divides the Vref voltage to a binary weighted value 4-bit value, with the 4-bits equal to X3 X2 X1 X0

If the switch  $X_n$  is connected to Vref, then that bit value is '1', if the switch  $X_n$  is not connected to Vref, then that bit value is '0'.

Majority of DACs use this architecture as requires far less resistors than flash DACs.

# Sample DAC Computations

If  $V_{ref} = 5V$ , and the 8-bit input code is 0x8A, what is the DAC output voltage?

$$\begin{aligned} \text{input\_code}/2^N * V_{ref} &= (0x8A)/2^8 * 5 \text{ V} \\ &= 138/256 * 5 \text{ V} = 2.70 \text{ V } (\text{V}_{out}) \end{aligned}$$

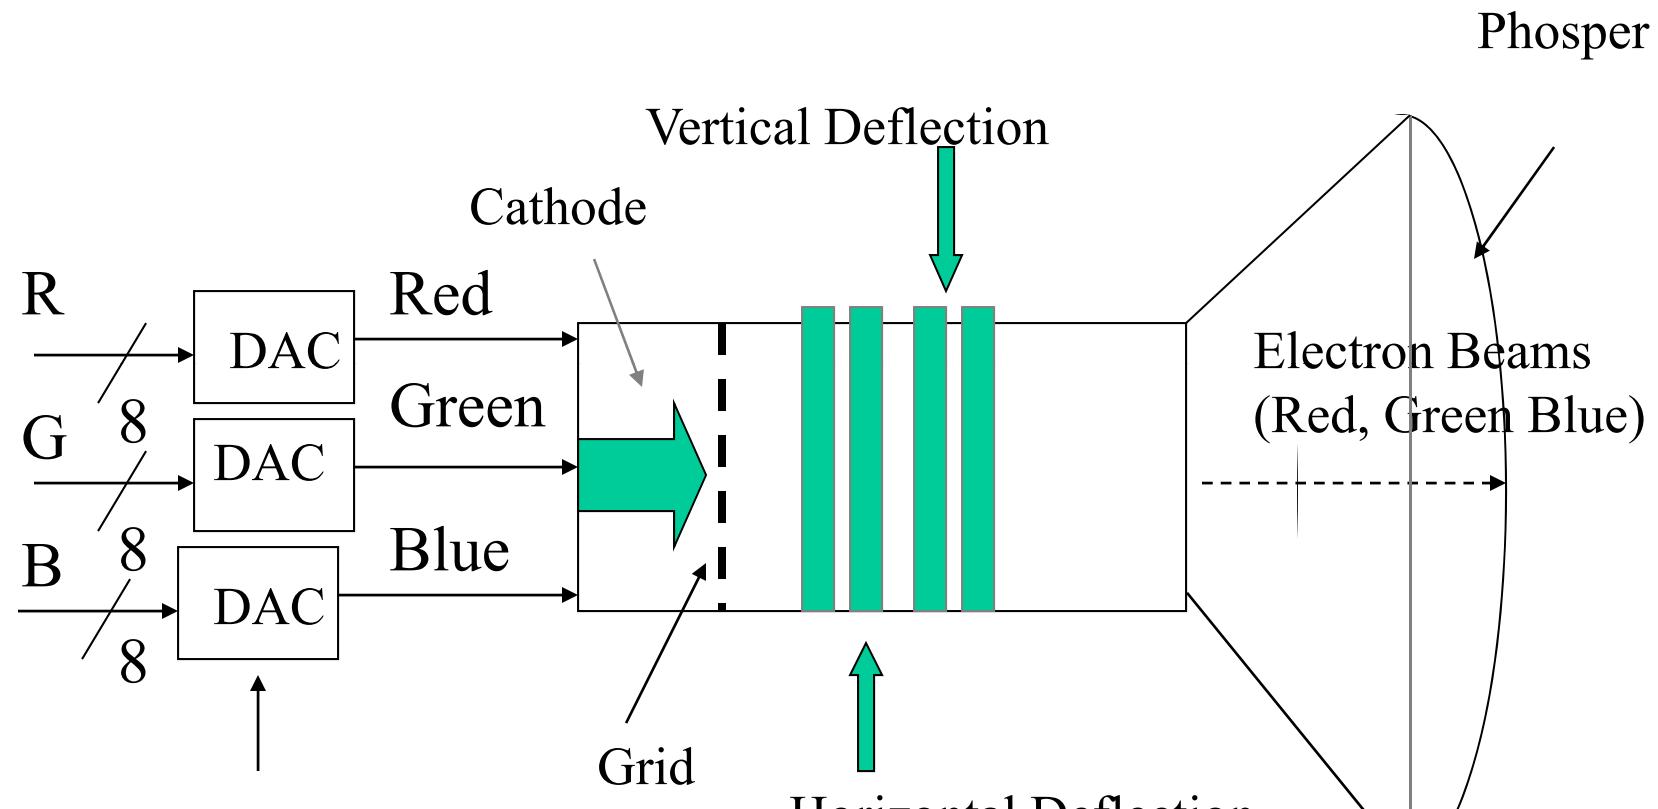

If  $V_{ref} = 4V$ , and the DAC output voltage is 1.25 V, what is the 8-bit input code?

$$\begin{aligned} \text{V}_{out}/V_{ref} * 2^N &= 1.25 \text{ V}/4 \text{ V} * 2^8 \\ &= 0.3125 * 256 = 80 = 0x50 \text{ (input\_code)} \end{aligned}$$

# Commercial DACs

- Either voltage or current DACs
  - Current DACs require an external operational amplifier to convert to voltage
- Precision up to 16 bits
- Key timing parameter is *settling time* - amount of time it takes to produce a stable output voltage once the input code has changed
- We will use an 8-bit voltage DAC with a SPI interface from Maxim semiconductor

# DAC Application

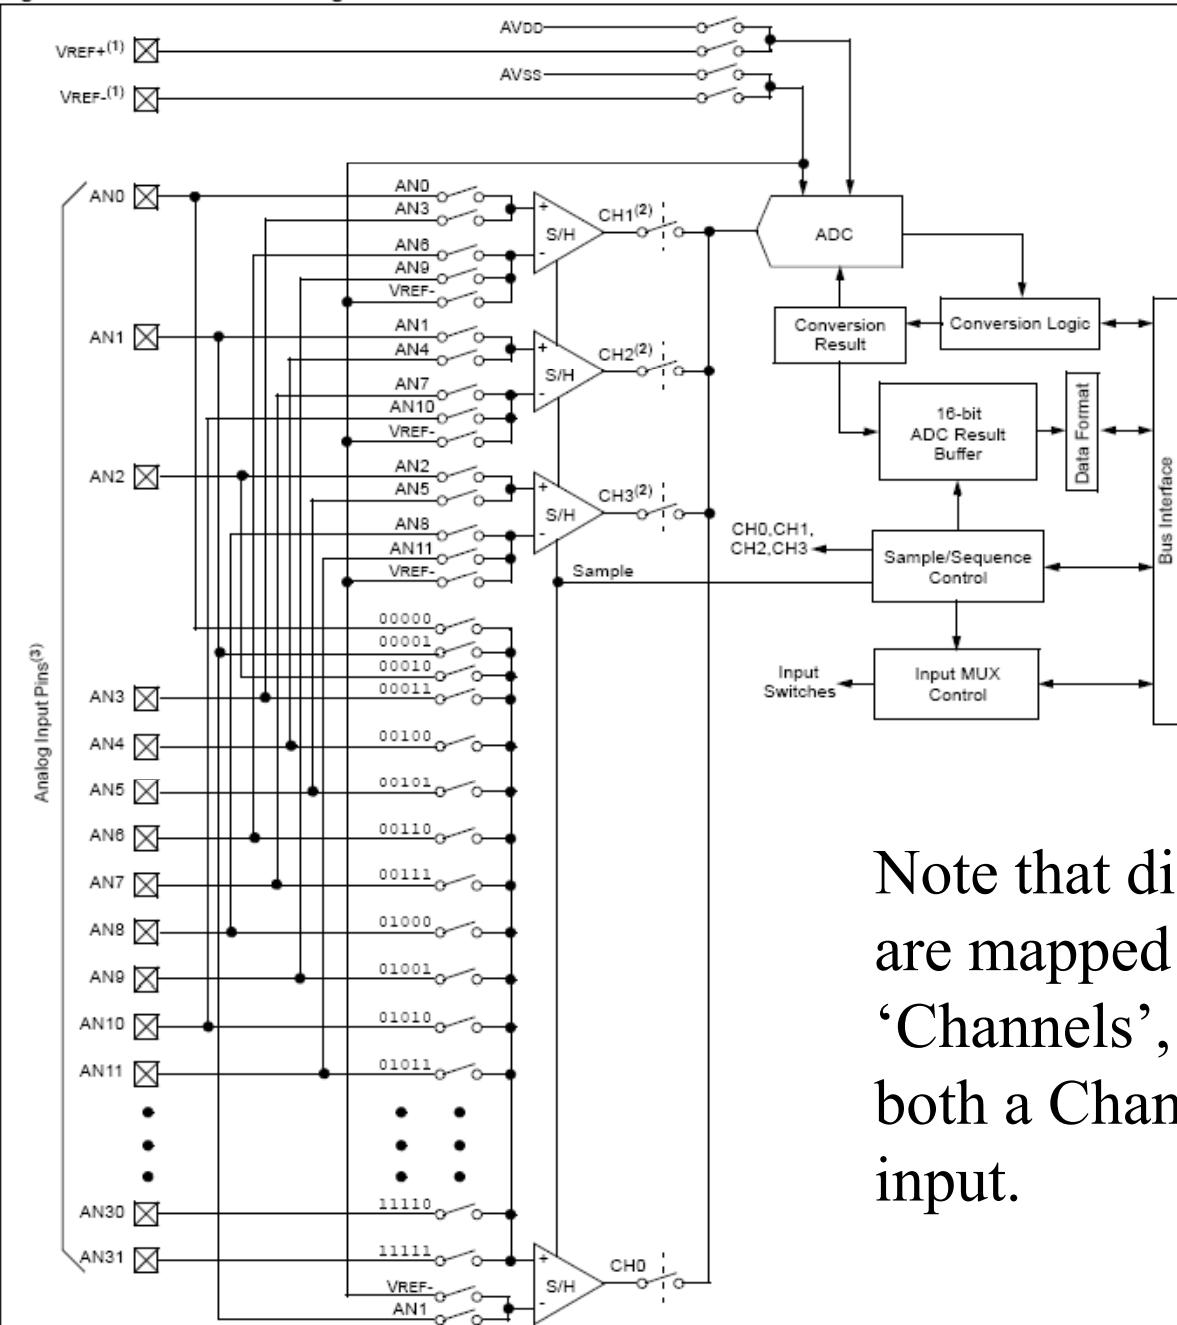

High speed video  
DACs produce RGB  
signals for color CRT

# PIC24 ADC

- The PIC24 µC has an onboard ADC
  - Successive approximation
  - 10-bit (default) or 12-bit resolution
  - Reference voltage can be Vdd or separate voltage (min AVSS + 2.7 V)
  - Multiple input (more than one input channel)
  - Clock source for ADC is either a divided Fosc, or an internally generated clock. The ADC clock period ( $T_{ad}$ ) cannot be less than 76 ns for 10-bit mode, or 118 ns for 12-bit mode. The internally generated clock has a period of  $\sim 250$  ns ( $\sim 4$  MHz).

Figure 16-1: ADC Block Diagram

# Block Diagram

Note that different  $\text{AN}_x$  inputs are mapped to different ‘Channels’, so have to select both a Channel and an  $\text{AN}_x$  input.

# Conversion Time

- Total conversion time is sampling time + conversion time
- Sampling looks at the input voltage and uses a storage capacitor to acquire the input.
  - This time is configurable; we will use a conservative 31 Tad periods which is the maximum for the PIC24HJGP202.
- Conversion time is Number of bits + 31 Tad periods.
- So, for these settings, takes  $31$  (sampling) +  $12$  (bits) +  $2$  =  $45$  clock periods.
- Using the internal clock ( $250$  ns), one conversion takes about  $11.25 \mu\text{s}$  ( $88.9$  kHz).

$$R_{ic} = 250 \Omega$$

$$R_s = 200 \Omega$$

$$R_{ss} = 3 k\Omega$$

$$Chold = 18 \text{ pF}$$

$$RC = 3.45 \text{ k}\Omega * 18 \text{ pF} = 61.2 \text{ n}$$

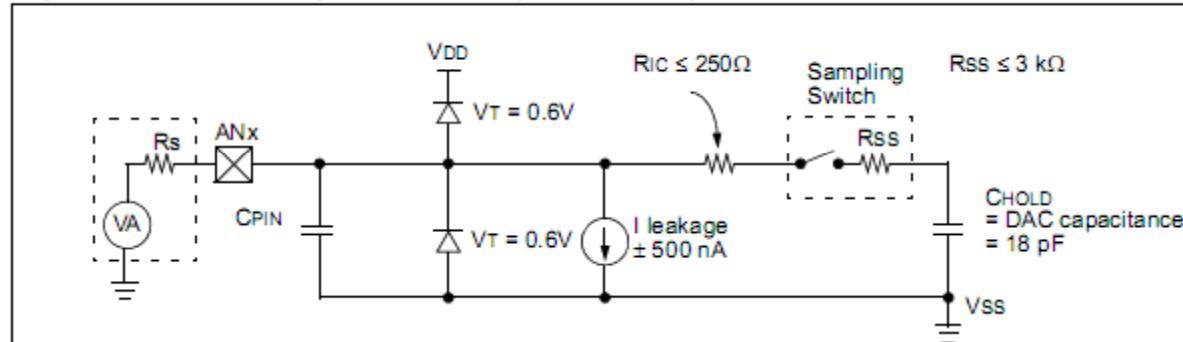

$$\frac{1}{2} \text{ LSB error} = .5 / 4096 =$$

$$0.0122 \text{ m} = 9.01 RC$$

$$9.01 RC * 61.2 \text{ n} = 0.56 \mu\text{s}$$

$$0.56 \mu\text{s} / 250 \text{ ns} = 2.2 \text{ Tad}, \text{ so } 31 \text{ round up to 3 Tad.}$$

Figure 28-17: Analog Input Model (12-bit Mode)

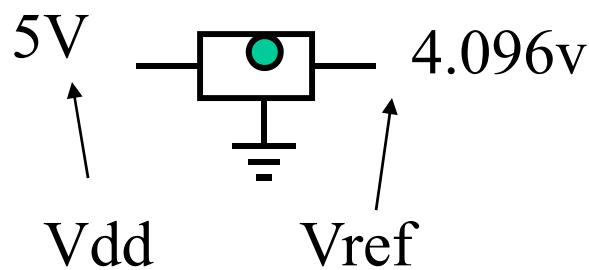

V 0.7

# Voltage References

Stability of voltage reference is critical for high precision conversions.

We will use Vdd as our voltage reference for convenience, but will be throwing away at least two bits of precision due to Vdd fluctuations.

Example commercial voltage reference: 2.048v, 2.5v , 3v, 3.3v, 4.096v, 5v (Maxim 6029). The PIC24H can only use a voltage reference of either 3.0 V or 3.3 V.

Key parameter for a voltage is stability over temperature operating range. Need this to be less than  $\frac{1}{2}$  of a LSB value.

# Configuring the ADC

```
void configADC1_ManualCH0(uint16 u16_Ch0PositiveMask,
                           uint8 u8_autoSampleTime, uint8 u8_Use12bits) {

    if (u8_autoSampleTime > 31) u8_autoSampleTime=31;
    AD1CON1bits.ADON = 0;      // turn off ADC (changing setting while ADON is
not allowed)

    /** Configure the internal ADC */
    AD1CON1 = ADC_CLK_AUTO + ADC_AUTO_SAMPLING_OFF;
    if (u8_Use12bits) AD1CON1 |= ADC_12BIT;
    AD1CON3 = ADC_CONV_CLK_INTERNAL_RC + (u8_autoSampleTime<<8);
    AD1CON2 = ADC_VREF_AVDD_AVSS;
    AD1CHS0 = ADC_CH0_NEG_SAMPLEA_VREFN + u16_Ch0PositiveMask;
    AD1CON1bits.ADON = 1;      //turn on the ADC

}
```

Configures for internal ADC clock, uses manual sample start/auto conversion, and **u16\_Ch0PositiveMask** selects the ANx input from Channel 0 to convert. Uses AVDD, AVSS as references. Parameter **u8\_autoSampleTime** sets the number of sample clocks, and **u8\_Use12bits** determines if 12-bit or 10-bit conversion is done.

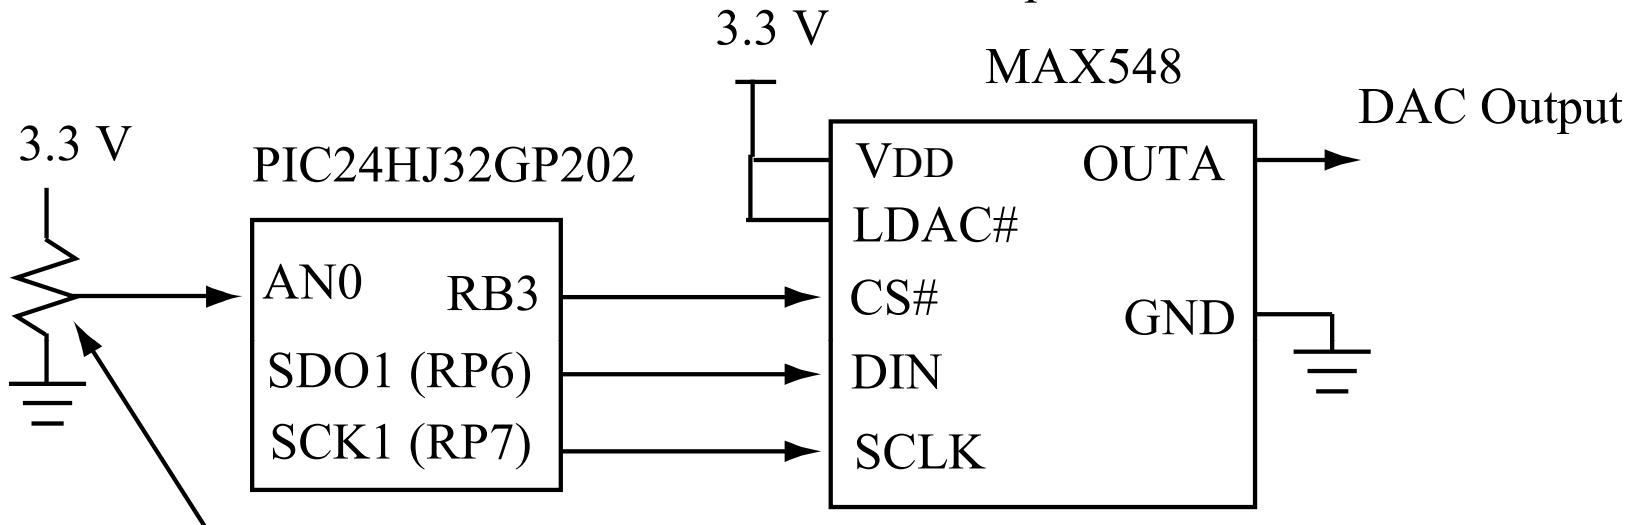

# Starting a Conversion, Getting result:

```
int16 convertADC1(void) {  
    SET_SAMP_BIT_AD1(); //start sampling  
    WAIT_UNTIL_CONVERSION_COMPLETE_AD1(); //wait for conversion to finish  
    return(ADC1BUF0);  
}
```

In this mode, tell ADC to start sampling, after sampling is done the ADC conversion is started, and then a status bit is set when the conversion is finished.

# Testing the ADC and DAC

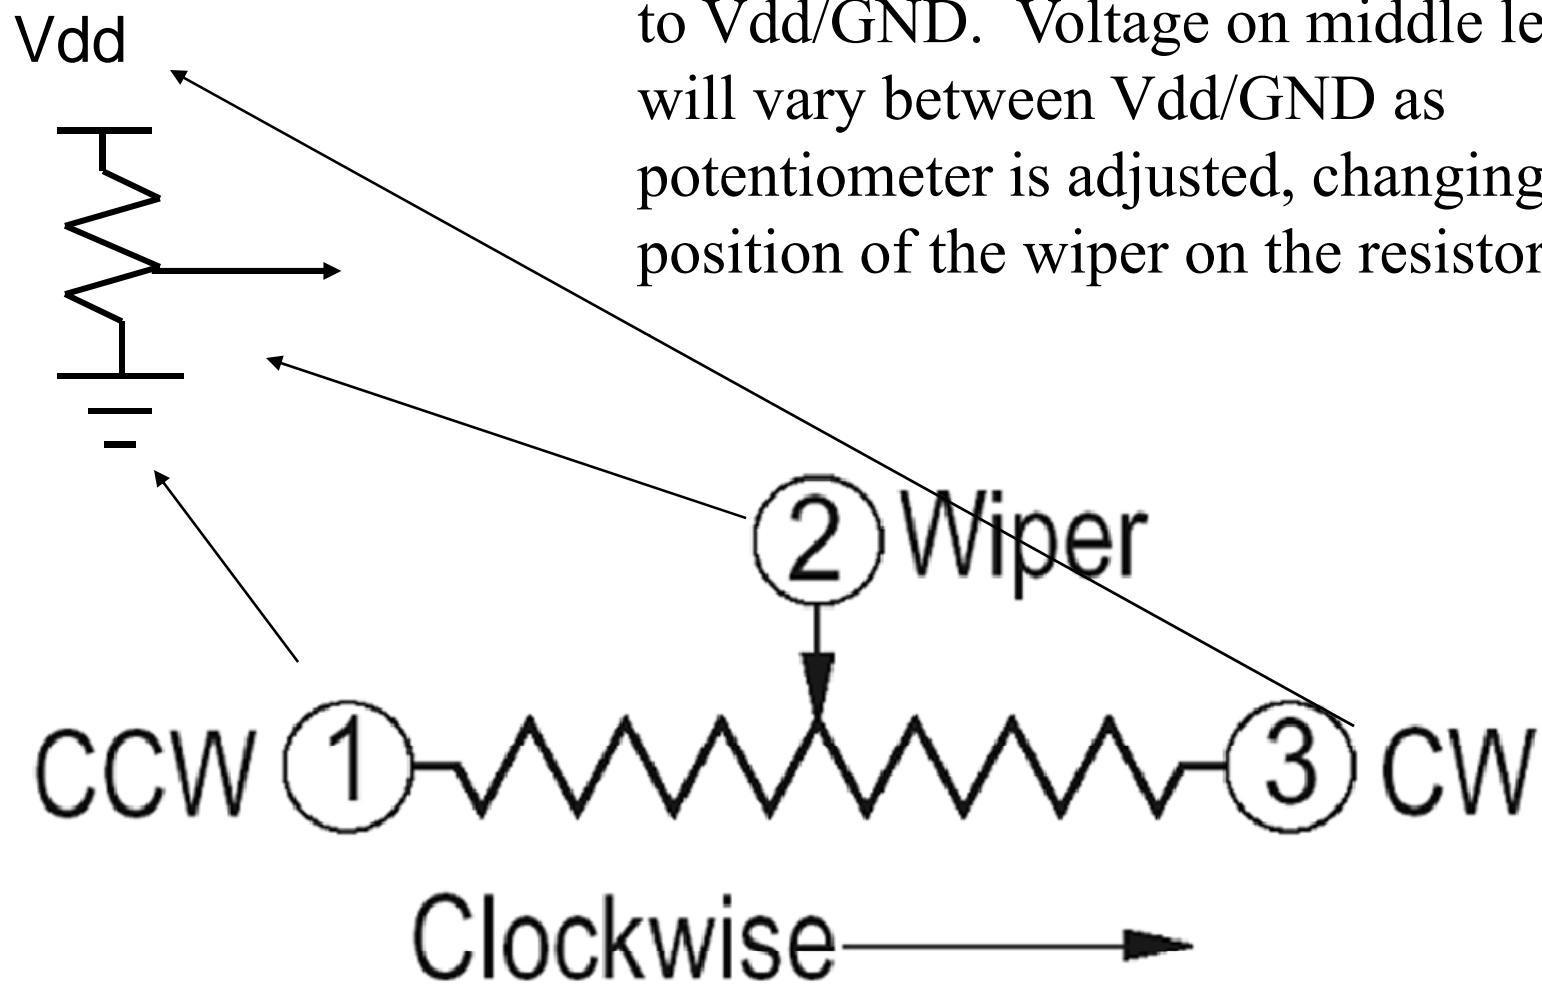

The MAX548 is an 8-bit DAC with a SPI port

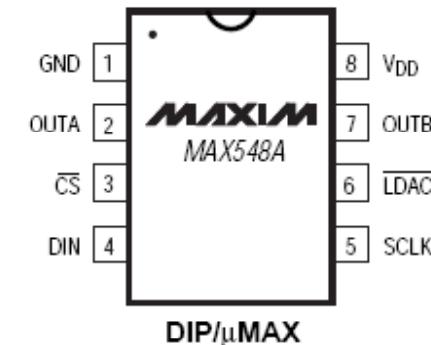

Potentiometer has three pins - middle pin is the wiper, connect the end pins to Vdd/Gnd (ordering does not matter).

Read the voltage from the potentiometer via the PIC24 ADC, write this digital value to the DAC. The DAC output voltage should match the potentiometer voltage.

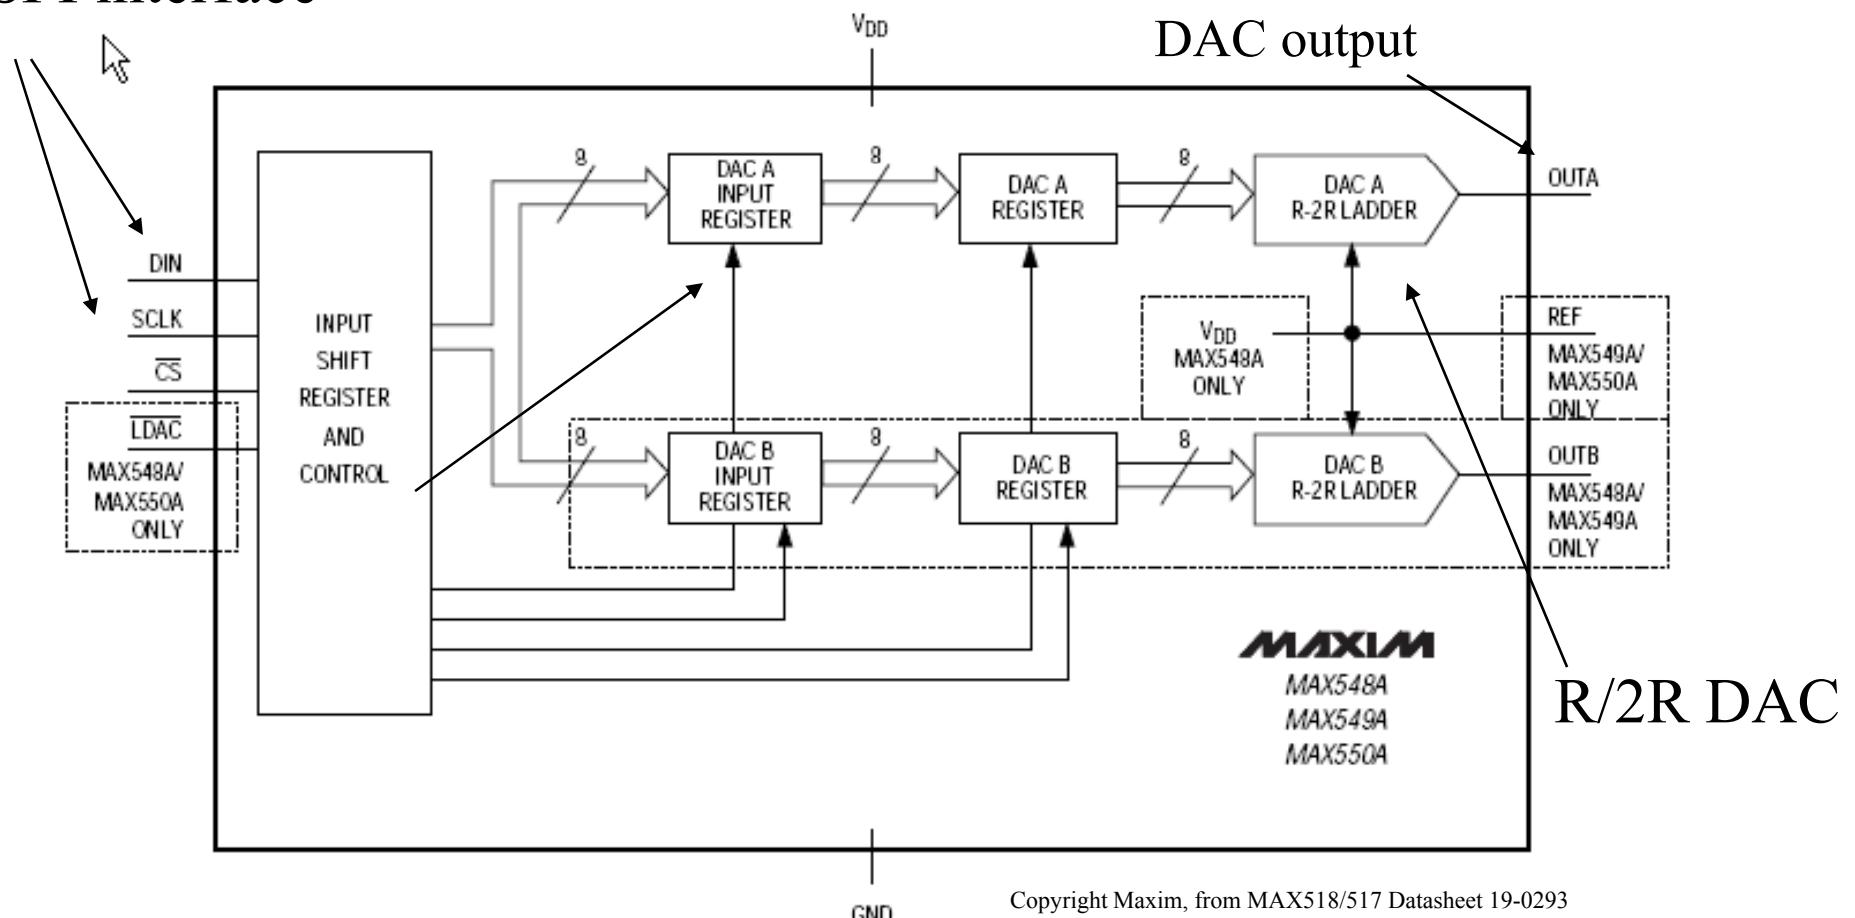

# Potentiometer

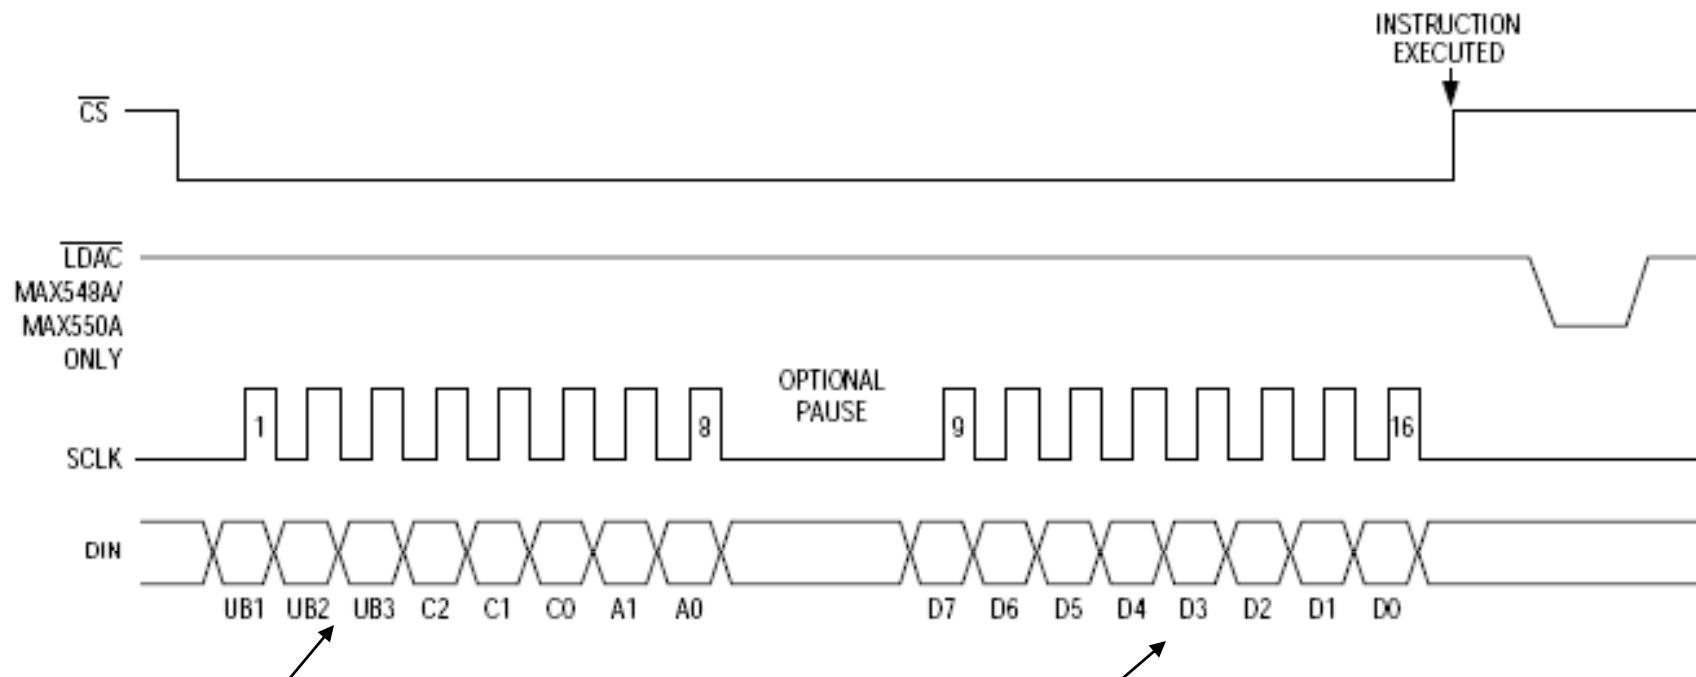

# MAXIM 548 DAC

## SPI interface

# Max548A SPI Command Format

First Byte: DAC  
command byte

Second Byte: Command data

Command byte to do conversion: 0x09 (0b00001001)

Data is the value to convert.

# Function for doing a DAC conversion:

```
#define CONFIG_SLAVE_ENABLE() CONFIG_RB8_AS_DIG_OUTPUT()

#define SLAVE_ENABLE()          _LATB8 = 0 //low true assertion
#define SLAVE_DISABLE()         _LATB8 = 1

void writeDAC (uint8 dacval) {
    SLAVE_ENABLE();           //assert Chipselect line to DAC
    ioMasterSPI1(0b00001001) //control byte that enables DAC A
    ioMasterSPI1(dacval);   //write DAC value
    SLAVE_DISABLE();
}
```

# adc\_spidac\_test.c

```
void configDAC() {  
    CONFIG_SLAVE_ENABLE();           //chip select for DAC  
    SLAVE_DISABLE();                //disable the chip select  
}  
  
int main(void) {  
    uint16 u16_adcVal;  
    uint8 u8_dacVal;  
    float f_adcVal;  
    float f_dacVal;  
  
    configBasic(HELLO_MSG);  
    CONFIG_AN0_AS_ANALOG();  
    configADCl_ManualCH0(ADC_CH0_POS_SAMPLEA_AN0, 31, 1);  
    configSPI1();  
    configDAC();  
    while (1) {
```

Support function,  
configures for manual  
sampling, auto conversion

Use input AN0 on Channel 0  
as ADC input

Number of sampling periods,  
31 is maximum for  
PIC24HJ32GP202

Value of ‘1’ selects 12-bit  
mode, ‘0’ selects 10-bit  
mode.

## adc\_spidac\_test.c (cont)

```
while (1) {
    u16_adcVal = convertADC1();      //get ADC value
    u8_dacVal = (u16_adcVal>>4) & 0x00FF;  //upper 8 bits to DAC value
    writeDAC(u8_dacVal);
    f_adcVal = u16_adcVal;
    f_adcVal = f_adcVal/4096.0 * VREF;  //convert to float 0.0 to VREF
    f_dacVal = u8_dacVal;
    f_dacVal = f_dacVal/256.0 * VREF;
    printf("ADC in: %4.3f V (0x%04x), To DAC: %4.3f V (0x%02x) \n",
           (double) f_adcVal, u16_adcVal, (double) f_dacVal, u8_dacVal);
    DELAY_MS(300);      //delay so that we do not flood the UART.
} //end while(1)
}
```

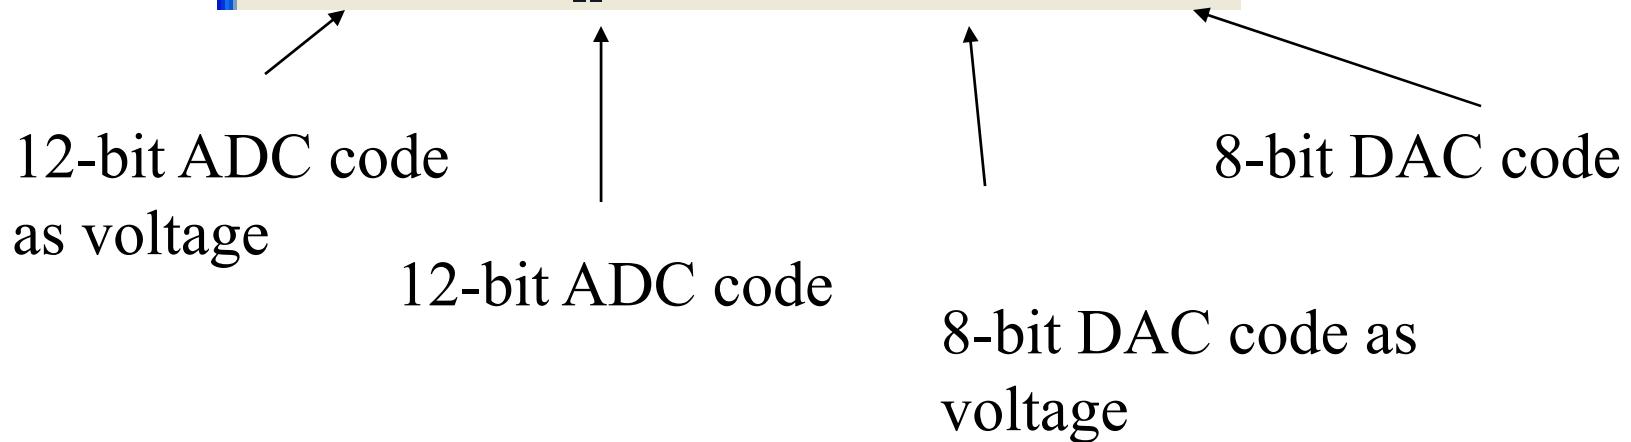

**u16\_adcVal** is 12-bit ADC value.

**f\_adcVal** is **u16\_adcVal** converted to a voltage between 0 – 3.3V using a float data type.

**u8\_dacVal** is the 8-bit value to send to the DAC (upper 8 bits of **u16\_adcVal** ).  
**f\_dacVal** is **u8\_dacVal** converted to a voltage between 0 – 3.3V using a float data type.

```

# Sensors

Temperature,

Angle,

Humidity,

Etc.

$$\text{Voltage} = F(\text{real\_world\_quantity})$$

The sensor has some function that maps the real world quantity into a voltage; the function can be either linear or non-linear.

A linear function is characterized by:

$$y = m * x + b$$

$$\text{voltage} = m * \text{real\_world\_quantity} + \text{offset}$$

# Example 1

An LM60 temperature sensor produces 6.25 mV for every  $1^{\circ}\text{C}$  and has a DC offset of 424 mV.

$$\text{Voltage (mV)} = 6.25 \text{ mV} * \text{Tcelsius} + 424 \text{ mV}$$

Question: Using a 10-bit ADC with  $V_{ref} = 3.3\text{V}$ , what is the ADC code value for a temperature of -10 Celsius?

Step 1: Convert temperature to voltage:

$$\text{Voltage (mV)} = 6.25 \text{ mV} * (-10) + 424 \text{ mV} = 361.5 \text{ mV} = 0.3615 \text{ V}$$

Step 2: Convert voltage to ADC code:

$$V_{in}/V_{ref} * 2^N = 0.3615/3.3 * 2^{10} = 112.17 = 112$$

## Example 1 (cont)

Can reduce the computations needed by simplifying the equation by combining steps:

Question: Using a 10-bit ADC with  $V_{ref} = 3.3V$ , what is the ADC code value for a temperature of -10 Celsius?

Step 1: Convert temperature to voltage:

$$\text{Voltage (mV)} = 6.25 \text{ mV} * (\text{Tcelsius}) + 424 \text{ mV}$$

$$\text{ADC code} = (0.00625 * \text{Tcelsius}) + 0.424 / 3.3 \text{ V} * 1024$$

$$\text{ADC code} = (6.4 * \text{Tcelsius}) + 434.176 / 3.3 \text{ V}$$

For  $\text{Tcelsius} = -10$

$$\begin{aligned}\text{ADC code} &= ((6.4 * -10) + 434.176) / 3.3 \\ &= 112.17 = 112\end{aligned}$$

## Example 2

A Freescale MPX5050 pressure sensor outputs 0.2 V at 0 kPa and has a sensitivity of 90 mV/kPa.

$$\text{Voltage (mV)} = 90 \text{ mV} * \text{Pressure\_kPa} + 200 \text{ mV}$$

Question: A 10-bit ADC with a  $V_{ref} = 3.3$  V returns a code value of 420. What pressure is being sensed by the pressure sensor?

Step 1: Convert ADC code to a voltage:

$$\text{adc\_code}/2^N * V_{ref} = 420/ 2^{10} * 3.3 \text{ V} = 1.354 \text{ V.}$$

Step 2: Convert Volts to pressure (solve the above equation for pressure):

$$\begin{aligned}\text{Pressure (kPa)} &= (\text{voltage (mV)} - 200 \text{ mV}) / 90 \text{ mV} \\ &= (1354 \text{ mV} - 200 \text{ mV})/90 \text{ mV} \\ &= 12.8 \text{ kPa}\end{aligned}$$
