

## FEATURES

- Timing from microseconds through hours
- Operates in both astable and monostable modes
- Adjustable duty cycle
- High current output can source or sink 200mA
- Output can drive TTL
- Temperature stability of 0.005%/°C

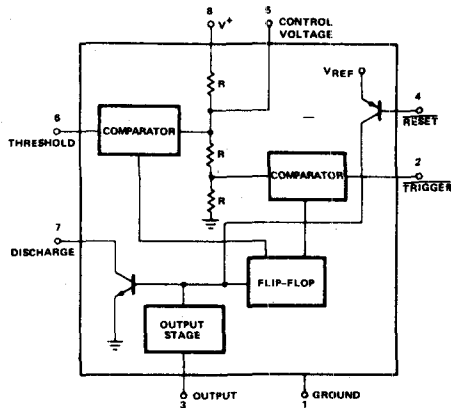

## APPLICATIONS

- Precision Timing
- Pulse Generation
- Sequential Timing
- Time Delay Generation
- Pulse Width Modulation
- Pulse Position Modulation
- Missing Pulse Detector

## GENERAL DESCRIPTION

The NE/SE 555 monolithic timing circuit is a highly stable controller capable of producing accurate time delays, or oscillation. Additional terminals are provided for triggering or resetting if desired. In the time delay mode of operation, the time is precisely controlled by one external resistor and one capacitor. For stable operation as an oscillator, the free running frequency and the duty cycle are both accurately controlled with two external resistors and one capacitor; the circuit may be triggered and reset on falling waveforms, and the output structure can source or sink large currents or drive TTL circuits.

APPLICATION INFORMATION

MONOSTABLE OPERATION

In this mode of operation, the timer functions as a one-shot. Initially the external capacitor (C) is held discharged by a transistor inside the timer. Upon application of a negative trigger pulse to pin 2, a flip-flop is set which releases the short circuit across the external capacitor and drives the

output high. The voltage across the capacitor increases exponentially with the time constant  $\tau = R_A C$ . When the voltage across the capacitor equals  $2/3 V^+$ , the comparator resets the flip-flop, which in turn discharges the capacitor rapidly and drives the output to its low state.

ASTABLE OPERATION

6

The circuit can also be connected to trigger itself and free run as a multivibrator. The external capacitor charges through  $R_A$  and  $R_B$  and discharges through  $R_B$  only. Thus the duty cycle may be precisely set by the ratio of these two resistors. In this mode of operation, the capacitor charges and discharges between  $1/3 V^+$  and  $2/3 V^+$ . As in the triggered mode,

the charge and discharge times, and therefore the frequency are independent of the supply voltage.

FREE RUNNING FREQUENCY vs.  $R_A$ ,  $R_B$  AND C

The frequency of oscillation is given by:  $f = \frac{1}{t} = \frac{1.46}{R_A + 2R_B C}$
