

Voltage-to-Frequency and Frequency-to-Voltage Converter

ADVFC32

FEATURES
High Linearity
± 0.01% max at 10kHz FS
± 0.05% max at 100kHz FS
± 0.2% max at 500kHz FS
Output TTL/CMOS Compatible
V/F or F/V Conversion
6 Decade Dynamic Range
Voltage or Current Input
Reliable Monolithic Construction

MIL-STD-883 Compliant Versions Available

PRODUCT DESCRIPTION

The industry standard ADVFC32 is a low cost monolithic voltageto-frequency (V/F) converter or frequency-to-voltage (F/V) converter with good linearity (0.01% max error at 10kHz) and operating frequency up to 0.5MHz. In the V/F configuration, positive or negative input voltages or currents can be converted to a proportional frequency using only a few external components. For F/V conversion, the same components are used with a simple biasing network to accommodate a wide range of input logic levels.

TTL or CMOS compatibility is achieved in the V/F operating mode using an open collector frequency output. The pullup resistor can be connected to voltages up to 30 volts, or to +15V or +5V for conventional CMOS or TTL logic levels. This resistor should be chosen to limit current through the open collector output to 8mA. A larger resistance can be used if driving a high impedance load.

Input offset drift is only 3ppm of full scale per °C, and full scale calibration drift is held to a maximum of 100ppm/°C (ADVFC32BH) due to a low T.C. zener diode.

The ADVFC32 is available in commercial, industrial, and extended temperature grades. The commercial grade is packaged in a 14-pin plastic DIP while the two wider temperature range parts are packaged in hermetically sealed TO-100 cans.

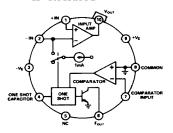

PRODUCT HIGHLIGHTS

 The ADVFC32 uses a charge balancing circuit technique (see Functional Block Diagram) which is well suited to high accuracy voltage-to-frequency conversion. The full-scale operating frequency is determined by only one precision resistor and capacitor. The tolerance of other support components (including the integration capacitor) is not critical. Inexpensive ± 20% resistors and capacitors can be used without affecting linearity or temperature drift.

PIN CONFIGURATION (TOP VIEW)

ONE SHOT SHOT OWNERATOR ONE ADVEC32

"H" PACKAGE - TO-100

- The ADVFC32 is easily configured to satisfy a wide range of system requirements. Input voltage scaling is set by selecting the input resistor which sets the input current to 0.25mA at the maximum input voltage.
- The same components used for V/F conversion can also be used for F/V conversion by adding a simple logic biasing network and reconfiguring the ADVFC32.
- The ADVFC32 is intended as a pin-for-pin replacement for VFC32 devices from other manufacturers.
- The ADVFC32 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current ADVFC32/883B data sheet for detailed specifications.

UNIPOLAR V/F, POSITIVE INPUT VOLTAGE

When operated as a V/F converter, the transformation from voltage to frequency is based on a comparison of input signal magnitude to the ImA internal current source.

A more complete understanding of the ADVFC32 requires a close examination of the internal circuitry of this part. Consider the operation of the ADVFC32 when connected as shown in Figure 1. At the start of a cycle, a current proportional to the

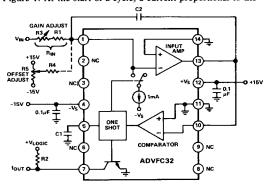

Figure 1. Connection Diagram for V/F Conversion, Positive Input Voltage

input voltage flows through R3 and R1 to charge integration capacitor C2. As charge builds up on C2, the output voltage of the input amplifier decreases. When the amplifier output voltage (pin 13) crosses ground (see Figure 2 at time t₁), the comparator

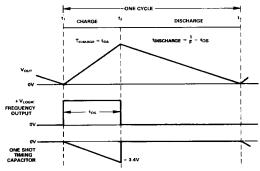

Figure 2. Voltage-to-Frequency Conversion Waveforms

triggers a one shot whose time period is determined by capacitor C1. Specifically, the one shot time period (in nanoseconds) is:

$$t_{OS} \cong (C_1 + 44pF) \times 6.7k\Omega$$

During this period, a current of ($1 \text{mA} - I_{1N}$) flows out of the integration capacitor. The total amount of charge depleted during one cycle is, therefore ($1 \text{mA} - I_{1N}$) \times t_{OS} . This charge is replaced during the remainder of the cycle to return the integrator to its original voltage. Since the charge taken out of C2 is equal to the charge that is put on C2 every cycle,

$$(1\text{mA} - I_{IN}) \times t_{OS} = I_{IN} \times \left(\frac{1}{F_{OUT}} - t_{OS}\right)$$

or, rearranging terms,

$$F_{OUT} = \frac{I_{IN}}{lmA \times t_{OS}}$$

The complete transfer equation can now be derived by substituting $I_{\rm IN} = V_{\rm IN}/R_{\rm IN}$ and the equation relating C1 and $t_{\rm OS}$. The final equation describing ADVFC32 operation is:

$$F_{OUT} = \frac{V_{IN}/R_{IN}}{1mA \times (C_1 + 44pF) \times 6.7k\Omega}$$

Components should be selected to optimize performance over the desired input voltage and output frequency range using the equations listed below:

$$\begin{split} C_1 &= \frac{3.7 \, \times \, 10^7 pF/sec}{F_{OUT \, FS}} \quad -44 pF \\ C_2 &= \frac{10^{-4} \, Farads/sec}{F_{OUT \, FS}} \left(1000 pF \, minimum\right) \\ R_{IN} &= \frac{V_{IN \, FS}}{0.25 mA} \\ R_2 &\geqslant \frac{+V_{LOGIC}}{8mA} \end{split}$$

Both $R_{\rm IN}$ and C_1 should have very low temperature coefficients as changes in their values will result in a proportionate change in the V/F transfer function. Other component values and temperature coefficients are not critical.

Table I. Suggested Values for C1, RIN and C2

V _{IN FS}	F _{OUT FS}	$\mathbf{C_1}$	R _{IN}	C ₂

10V	100kHz	330pF	40kΩ	1000pF	

V/F & F/V CONVERTERS 3-53

ADVFC32

Input resistance $R_{\rm IN}$ is composed of a fixed resistor (R1) and a variable resistor (R3) to allow for initial gain error compensation. To cover all possible situations, R3 should be 20% of $R_{\rm IN}$, and R1 should be 90% of $R_{\rm IN}$. This allows a \pm 10% gain adjustment to compensate for the ADVFC32 full-scale error and the tolerance of C1.

If more accurate initial offset is required, the circuit of R4 and R5 can be added. R5 can have a value between $10k\Omega$ and $100k\Omega$, and R4 should be approximately $10M\Omega$. The amount of current required to trim zero offset will be relatively small, so the temperature coefficients of these resistors are not critical. If large offsets are added using this circuit, temperature drift of both of these resistors is much more important.

BIPOLAR V/F

By adding another resistor from pin 1 (pin 2 of TO-100 can) to a stable positive voltage, the ADVFC32 can be operated with a bipolar input voltage. For example, an $80 \mathrm{k}\Omega$ resistor to $+10 \mathrm{V}$ causes an additional current of $0.125 \mathrm{mA}$ to flow into the integrator so that the net current flow to the integrator is positive even for negative input voltages. At negative full scale input voltage, $0.125 \mathrm{mA}$ will flow into the integrator from $\mathrm{V_{IN}}$ cancelling out the $0.125 \mathrm{mA}$ from the offset resistor, resulting in an output frequency of zero. At positive full scale, the sum of the two currents will be $0.25 \mathrm{mA}$ and the output will be at its maximum frequency

UNIPOLAR V/F, NEGATIVE INPUT VOLTAGE

Figure 3 shows the connection diagram for V/F conversion of negative input voltages. In this configuration full scale output frequency occurs at negative full scale input, and zero output frequency corresponds to zero input voltage.

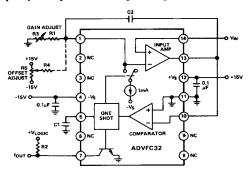

Figure 3. Connection Diagram for V/F Conversion, Negative Input Voltage

A very high impedance signal source may be used since it only drive the noninverting integrator input. Typical input impedance at this terminal is 250MΩ or higher. For V/F conversion of positive input signals the signal generator must be able to source 0.25mA to properly drive the ADVFC32, but for negative V/F conversion the 0.25mA integration current is drawn from ground through R1 and R3.

Circuit operation for negative input voltages is very similar to positive input unipolar conversion described in the previous section. For best operating results use component equations listed in that section.

F/V CONVERSION

Although the mathematics of F/V conversion can be very complex, the basic principle is easy to understand. Figure 4 shows the connection diagram for F/V conversion with TTL input logic levels. Each time the input signal crosses the comparator threshold going negative, the one shot is activated and switches ImA into the integrator input for a measured time period (determined by C1). As the frequency increases, the amount of charge injected into the integration capacitor increases proportionately. The voltage across the integration capacitor is stabilized when the leakage current through R1 and R3 equals the average current being switched into the integrator. The net result of these two effects is an average output voltage which is proportional to the input frequency. Optimum performance can be obtained by selecting components using the same guidelines and equations listed in the V/F conversion section.

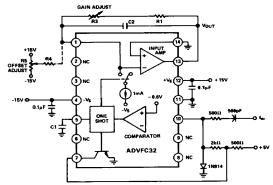

Figure 4. Connection Diagram for F/V Conversion, TTL Input

DECOUPLING

Decoupling power supplies at the device is good practice in any system, but absolutely imperative in high resolution applications. For the ADVFC32, it is important to remember where the voltage transients and ground currents flow. For example, the current drawn through the output pulldown transistor originates from the logic supply, and is directed to ground through pin 11 (pin 8 of TO-100). Therefore, the logic supply should be decoupled near the ADVFC32 to provide a low impedance return path for switching transients. Also, if there is a separate digital ground it should be connected to the analog ground at the ADVFC32. This will prevent ground offsets that could be created by directing the full 8mA output current into the analog ground, and subsequently back to the logic supply.

Although some circuits may operate satisfactorily with the power supplies decoupled at only one location on each board, this practice is not recommended for the ADVFC32. For best results, each supply should be decoupled with $0.1\mu F$ capacitor at the ADVFC32. In addition, a larger board level decoupling capacitor of $1\mu F$ to $10\mu F$ should be located relatively close to the ADVFC32 on each power supply.

COMPONENT TEMPERATURE COEFFICIENTS

The drift specifications of the ADVFC32 do not include temperature effects of any of the supporting resistors or capacitors. The drift of the input resistors R1 and R3 and the timing capacitor C₁ directly affect the overall temperature stability. In the application of Figure 2, a 10ppm/°C input resistor used with a

REV. A

Application Hints—ADVFC32

100ppm/°C capacitor may result in a maximum overall circuit gain drift of:

 $100ppm/^{\circ}C (ADVFC32BH) + 100ppm/^{\circ}C (C1) + 10ppm/^{\circ}C (R_{IN}) = 210ppm/^{\circ}C$

Although $R_{\rm IN}$ and C_1 have the most pronounced effect on temperature stability, the offset circuit of resistors R4 and R5 may also have a slight effect on the offset temperature drift of the circuit. The offset will change with variations in the resistance of R4 and supply voltage changes. In most applications the offset adjustment is very small, and the offset drift attributable to this circuit will be negligible. In the bipolar mode, however, both the positive reference and the resistor used to offset the signal range will have a pronounced effect on offset drift. A high quality reference and resistor should be used to minimize offset drift errors.

Other circuit components do not directly influence temperature performance as long as their actual values are not so different from nominal value as to preclude operation. This includes integration capacitor C2. A change in the capacitance value of C2 results in a different rate of voltage change across C2, but this is compensated by an equal effect when C2 is discharged by the switched 1mA current source so that no net effect occurs.

The temperature effects of the components described above are the same when the ADVFC32 is configured for negative or bipolar input ranges, or F/V conversion.

OTHER CIRCUIT CONSIDERATIONS

The input amplifier connected to pins 1, 13, and 14 is not a standard operational amplifier. Although it operates like an op amp in most applications, two key differences should be noted. First, the bias current of the positive input is typically 40nA

while the bias current of the inverting input is ±8nA. Therefore, any attempt to cancel input offset voltage due to bias currents by matching input resistors will create worse offsets. Second, the output of this amplifier will sink only 1mA, even though it will source as much as 10mA. When used in the F/V mode, the amplifier must be buffered if large sink currents are required.

MICROPROCESSOR OPERATED A/D CONVERTER

With the addition of a few external components the ADVFC32 can be used as a $\pm\,10V$ A/D microprocessor front end. Although the nonlinearity of the ADVFC32 is only 0.05% maximum (0.01% typ), the resolution is much higher, allowing it to be used in 16-bit measurement and control systems where a monotonic transfer function is essential. The resolution of the circuit shown in Figure 5 is dependent on the amount of time allowed to count the ADVFC32 frequency output. Using a full scale frequency of 100kHz, an 8-bit conversion can be made in about 10ms, and a 2 second time period allows a 16-bit measurement, including offset and gain calibration cycles.

As shown in Figure 5, the input signal is selected via the AD7590 input multiplexer. Positive and negative references as well as a ground input are provided to calibrate the A/D. This is very important in systems subject to moderate or extreme temperature changes since the gain temperature coefficient of the ADVFC32 is as high as ± 150 ppm/°C. By using the calibration cycles, the A/D conversion will be as accurate as the references provided. The AD542 following the input multiplexer provides a high impedance input (10^{12} ohms) and buffers the switch resistance from the relatively low impedance ADVFC32 input.

If higher linearity is required, the ADVFC32 can be operated at 10kHz, but this will require a proportionately longer conversion time. Conversely, the conversion time can be decreased at the expense of nonlinearity by increasing the maximum frequency to as high as 500kHz.

V/F & F/V CONVERTERS 3-55

ADVFC32

HIGH NOISE IMMUNITY, HIGH CMRR ANALOG DATA LINK

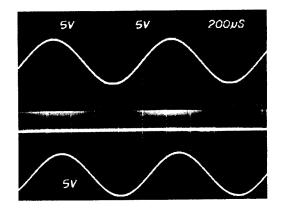

In many applications, a signal must be sensed at a remote site and sent through a very noisy environment to a central location for further processing. In these cases, even a shielded cable may not protect the signal from noise pickup. The circuit of Figure 6 provides a solution in these cases. Due to the optocoupler and voltage-to-frequency conversion, this data link is extremely insensitive to noise and common mode voltage interference. For even more protection, an optical fiber link substituted for the HCPL2630 will provide common mode rejection of more than several hundred kilovolts and virtually total immunity to electrical noise. For most applications, however, the frequency modulated signal has sufficient noise immunity without using an optical fiber link, and the optocoupler provides common mode isolation up to 3000V dc.

The data link input voltage is changed in a frequency modulated signal by the first ADVFC32. A 42.2k Ω input resistor and a 100k Ω offset resistor set the scaling so that a 0V input signal corresponds to 50kHz, and a 10V input results in the maximum output frequency of 500kHz. A high frequency optocoupler is then used to transmit the signal across any common mode voltage potentials to the receiving ADVFC32. The optocoupler is not necessary in systems where common mode noise is either very small or a constant low level dc voltage. In systems where common mode voltage may present a problem, the connection between the two locations should be through the optocoupler; no power or ground connections need to be made.

The output of the optocoupler drives an ADVFC32 hooked up in the F/V configuration. Since the reconstructed signal at pin 10 has a considerable amount of carrier feedthrough, it is desirable to filter out any frequencies in the carrier range of 50kHz to 500kHz. The frequency response of the F/V converter is only 3kHz due to the pole made by the integrator, so a second 3kHz

filter will not significantly limit the bandwidth. With the simple one pole filter shown in Figure 6, the input to output 3dB point is approximately 2kHz, and the output noise is less than 15mV. If a lower output impedance drive is needed, a two pole active filter is recommended as an output stage.

Although the F/V conversion technique used in this circuit is quite simple, it is also very limited in terms of its frequency response and output ripple. The frequency response is limited by the integrator time constant and while it is possible to decrease that time constant, either signal range or output ripple must be sacrificed. The performance of the circuit of Figure 6 is shown in the photograph below. The top trace is the input signal, the middle trace is the frequency-modulated signal at the optocoupler's output, and the bottom trace is the recovered signal at the output of the F/V converter.
