

## QUAD POWER AMPLIFIER FOR CAR RADIO

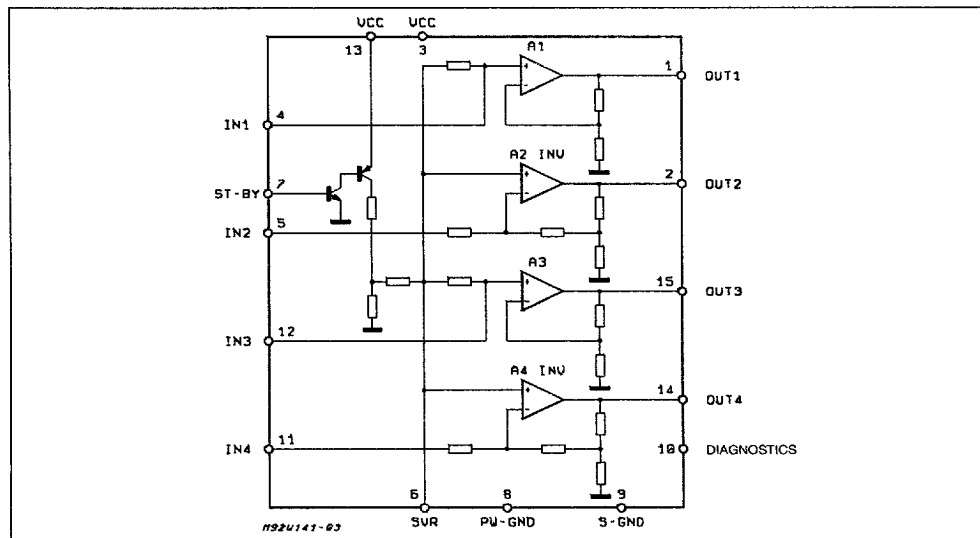

ADVANCE DATA

- HIGH OUTPUT POWER CAPABILITY
  - 2 x 25W/4Ω @ 14.4V, 1KHz, 10%
  - 4 x 7W/4Ω @ 14.4V, 1KHz, 10%
  - 4 x 12W/2Ω @ 14.4V, 1KHz, 10%
- MINIMUM EXTERNAL COMPONENTS COUNT:
  - NO BOOTSTRAP CAPACITORS
  - NO BOUCHEROT CELLS
  - INTERNALLY FIXED GAIN (26dB BTL)
- ST-BY FUNCTION (CMOS COMPATIBLE)
- NO AUDIBLE POP DURING ST-BY OPERATIONS
- DIAGNOSTICS FACILITY FOR:
  - CLIPPING
  - OUT TO GND SHORT
  - OUT TO V<sub>S</sub> SHORT
  - SOFT SHORT AT TURN-ON
  - THERMAL SHUTDOWN PROXIMITY

### Protections:

- OUTPUT AC/DC SHORT CIRCUIT
  - TO GND

### BLOCK DIAGRAM

MULTIWATT15

 ORDERING NUMBERS: TDA7375V  
 TDA7375H

- TO V<sub>S</sub>
- ACROSS THE LOAD
- SOFT SHORT AT TURN-ON
- OVERRATING CHIP TEMPERATURE WITH SOFT THERMAL LIMITER
- LOAD DUMP VOLTAGE SURGE
- VERY INDUCTIVE LOADS
- FORTUITOUS OPEN GND
- REVERSED BATTERY
- ESD

**DESCRIPTION**

The TDA7375 is a new technology class AB car radio amplifier able to work either in DUAL BRIDGE or QUAD SINGLE ENDED configuration.

The exclusive fully complementary structure of

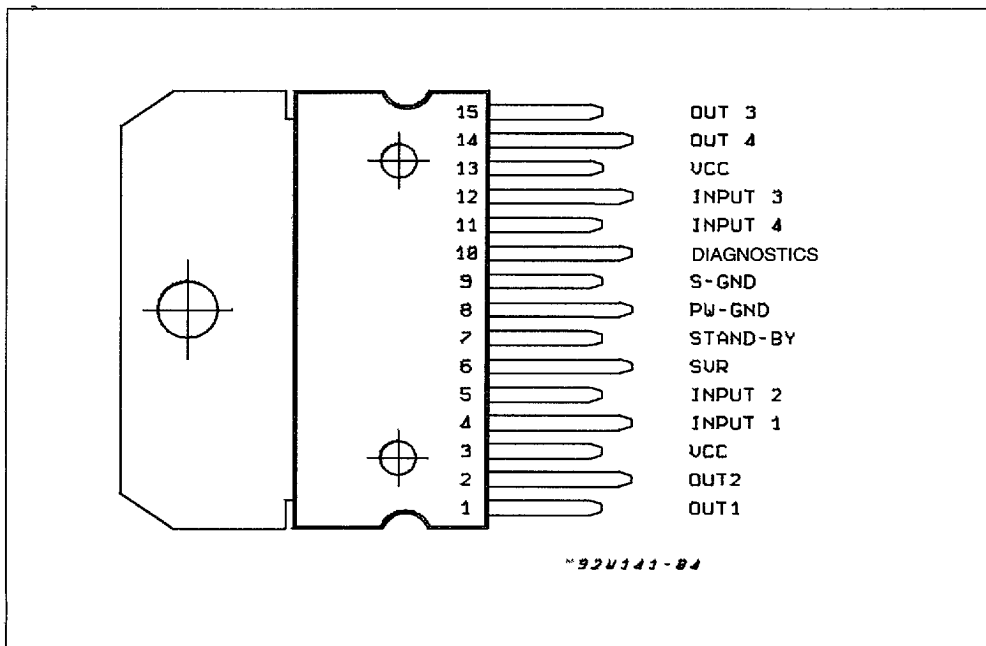

the output stage and the internally fixed gain guarantees the highest possible power performances with extremely reduced component count. The on-board clip detector simplifies gain compression operation. The fault diagnostics makes it possible to detect mistakes during car radio set assembly and wiring in the car.

**ABSOLUTE MAXIMUM RATINGS**

Symbol	Parameter	Value	Unit
$V_{op}$	Operating Supply Voltage	18	V
$V_S$	DC Supply Voltage	28	V
$V_{peak}$	Peak Supply Voltage (for $t = 50ms$ )	50	V
$I_o$	Output Peak Current (not repetitive $t = 100\mu s$ )	4.5	A
$I_o$	Output Peak Current (repetitive $f > 10Hz$ )	3.5	A
$P_{tot}$	Power Dissipation ( $T_{case} = 85^\circ C$ )	36	W
$T_{stg}, T_J$	Storage and Junction Temperature	-40 to 150	$^\circ C$

**THERMAL DATA**

Symbol	Description	Value	Unit
$R_{th j-case}$	Thermal Resistance Junction-case	Max 1.8	$^\circ C/W$

**PIB CONNECTION (Top view)**

**ELECTRICAL CHARACTERISTICS** (Refer to the test circuit,  $V_S = 14.4V$ ;  $R_L = 4\Omega$ ;  $f = 1KHz$ ;  
 $T_{amb} = 25^\circ C$ , unless otherwise specified)

Symbol	Parameter	Test Condition	Min.	Typ.	Max.	Unit
$V_S$	Supply Voltage Range		8		18	V
$I_d$	Total Quiescent Drain Current	$R_L = \infty$			150	mA
$V_{OS}$	Output Offset Voltage				150	mV
$P_O$	Output Power	(each channel) $d = 10\%$ ; $R_L = 4\Omega$ Bridge Single Ended $R_L = 2\Omega$	20 6.5	25 7 12		W W W

## GENERAL STRUCTURE

### High Application Flexibility

The availability of 4 independent channels makes it possible to accomplish several kinds of applications ranging from 4 speakers stereo (F/R) to 2 speakers bridge solutions.

In case of working in single ended conditions the polarity of the speakers driven by the inverting amplifier must be reversed respect to those driven by non inverting channels.

This is to avoid phase inconveniences causing sound alterations especially during the reproduction of low frequencies.

### Easy Single Ended to Bridge Transition

The change from single ended to bridge configurations is made simply by means of a short circuit across the inputs, that is no need of further external components.

### Gain Internally Fixed to 20dB in Single Ended, 26dB in Bridge

Advantages of this design choice are in terms of:

- components and space saving
- output noise, supply voltage rejection and distortion optimization.

### Silent Turn On/Off and Muting/Stand-by Function

The stand-by can be easily activated by means of a CMOS level applied to pin 7 through a RC filter. Under stand-by condition the device is turned off completely (supply current =  $1\mu\text{A}$  typ.; output attenuation = 80dB min.).

Every ON/OFF operation is virtually pop free.

Furthermore, at turn-on the device stays in muting condition for a time determined by the value assigned to the SVR capacitor.

While in muting the device outputs becomes insensitive to any kinds of signal that may be present at the input terminals. In other words every transient coming from previous stages produces no unpleasant acoustic effect to the speakers.

### STAND-BY DRIVING (pin 7)

Some precautions have to be taken in the definition of stand-by driving networks: pin 7 cannot be directly driven by a voltage source whose current capability is higher than 5mA. In practical cases a series resistance has always to be inserted, having it the double purpose of limiting the current at pin 7 and to smooth down the stand-by ON/OFF transitions - in combination with a capacitor - for output pop prevention.

In any case, a capacitor of at least 100nF from pin 7 to S-GND, with no resistance in between, is necessary to ensure correct turn-on.

## OUTPUT STAGE

The fully complementary output stage was made possible by the development of a new component: the ST exclusive power ICV PNP.

A novel design based upon the connection shown in fig. 20 has then allowed the full exploitation of its possibilities.

The clear advantages this new approach has over classical output stages are as follows:

### ■ Rail-to-Rail Output Voltage Swing With No Need of Bootstrap Capacitors.

The output swing is limited only by the VCEsat of the output transistors, which is in the range of  $0.3\Omega (R_{sat})$  each.

Classical solutions adopting composite PNP-NPN for the upper output stage have higher saturation loss on the top side of the waveform. This unbalanced saturation causes a significant power reduction. The only way to recover power consists of the addition of expensive bootstrap capacitors.

### ■ Absolute Stability Without Any External Compensation.

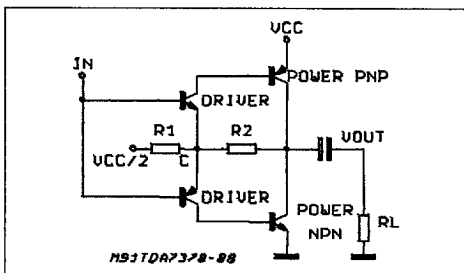

Referring to the circuit of fig. 20 the gain  $V_{out}/V_{in}$  is greater than unity, approximately  $1+R_2/R_1$ . The DC output ( $V_{cc}/2$ ) is fixed by an auxiliary amplifier common to all the channels.

By controlling the amount of this local feedback it is possible to force the loop gain ( $A^*B$ ) to less than unity at frequency for which the phase shift is  $180^\circ$ . This means that the output buffer is intrinsically stable and not prone to oscillation.

Most remarkably, the above feature has been achieved in spite of the very low closed loop gain of the amplifier.

In contrast, with the classical PNP-NPN stage, the solution adopted for reducing the gain at high frequencies makes use of external RC networks, namely the Boucherot cells.

Figure 20: The New Output Stage

### BUILT-IN SHORT CIRCUIT PROTECTION

Reliable and safe operation, in presence of all kinds of short circuit involving the outputs is assured by BUILT-IN protectors. Additionally to the AC/DC short circuit to GND, to  $V_s$ , across the speaker, a SOFT SHORT condition is signalled out during the TURN-ON PHASE so assuring correct operation for the device itself and for the loudspeaker.

This particular kind of protection acts in a way to avoid that the device is turned on (by ST-BY) when a resistive path (less than 16 ohms) is present between the output and GND. As the involved circuitry is normally disabled when a current higher than 5mA is flowing into the ST-BY pin, it is important, in order not to disable it, to have the external current source driving the ST-BY pin limited to 5mA.

This extra function becomes particularly attractive when, in the single ended configuration, one capacitor is shared between two outputs (see fig. 21).

Figure 21.

Supposing that the output capacitor  $C_{out}$  for any reason is shorted, the loudspeaker will not be damaged being this soft short circuit condition revealed.

### Diagnostics Facility

The TDA7375 is equipped with a diagnostic circuitry able to detect the following events:

- Clipping in the output signal
- Thermal shutdown
- Output fault:
  - short to GND
  - short to  $V_s$
  - soft short at turn on

The information is available across an open collector output (pin 10) through a current sinking when the event is detected

Figure 22: Clipping Detection Waveforms

A current sinking at pin 10 is triggered when a certain distortion level is reached at any of the outputs. This function allows gain compression possibility whenever the amplifier is overdriven.

### Thermal Shutdown

In this case the output 10 will signal the proximity of the junction temperature to the shutdown threshold. Typically current sinking at pin 10 will start  $\sim 10^\circ\text{C}$  before the shutdown threshold is reached.

Figure 23: Output Fault Waveforms (see fig. 24)

Figure 24: Fault Waveforms

### HANDLING OF THE DIAGNOSTICS INFORMATION

As various kinds of information is available at the same pin (clipping detection, output fault, thermal

proximity), this signal must be handled properly in order to discriminate each event.

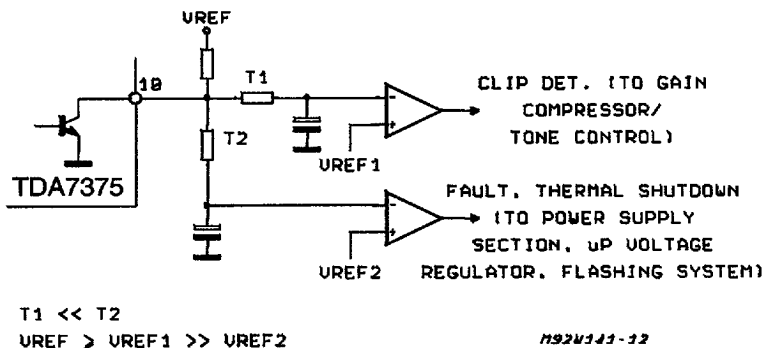

This could be done by taking into account the different timing of the diagnostic output during each case.

Figure 25: Waveforms

Normally the clip detector signalling produces a low level at pin 10 that is shorter than that present under faulty conditions; based on this assumption

Figure 26.

#### PCB-LAYOUT GROUNDING (general rules)

The device has 2 distinct ground leads, P-GND (POWER GROUND) and S-GND (SIGNAL GROUND) which are practically disconnected from each other at chip level. Proper operation requires that P-GND and S-GND leads be connected together on the PCB-layout by means of reasonably low-resistance tracks.

As for the PCB-ground configuration, a star-like arrangement whose center is represented by the supply-filtering electrolytic capacitor ground is highly advisable. In such context, at least 2 separate paths have to be provided, one for P-GND and one for S-GND. The correct ground assign-

ments are as follows:

STANDBY CAPACITOR, pin 7 (or any other standby driving networks): on S-GND

SVR CAPACITOR (pin 6): on S-GND and to be placed as close as possible to the device.

INPUT SIGNAL GROUND (from active/passive signal processor stages): on S-GND.

SUPPLY FILTERING CAPACITORS (pins 3,13): on P-GND. The (-) terminal of the electrolytic capacitor has to be directly tied to the battery (-) line and this should represent the starting point for all the ground paths.
