

CD4046A Types

CMOS Micropower Phase-Locked Loop

The RCA-CD4046A CMOS Micropower Phase-Locked Loop (PLL) consists of a low-power, linear voltage-controlled oscillator (VCO) and two different phase comparators having a common signal-input amplifier and a common comparator input. A 5.2-V zener diode is provided for supply regulation if necessary.

These types are supplied in 16-lead hermetic dual-in-line ceramic packages (D and F suffixes), 16-lead dual-in-line plastic package (E suffix), 16-lead ceramic flat packages (K suffix), and in chip form (H suffix).

VCO Section

The VCO requires one external capacitor C1 and one or two external resistors (R1 or R1 and R2). Resistor R1 and capacitor C1 determine the frequency range of the VCO and resistor R2 enables the VCO to have a frequency offset if required. The high input impedance ( $10^{12}\Omega$ ) of the VCO simplifies the design of low-pass filters by permitting the designer a wide choice of resistor-to-capacitor ratios. In order not to load the low-pass filter, a source-follower output of the VCO input voltage is provided at terminal 10 (DEMOMULATED OUTPUT). If this terminal is used, a load resistor ( $R_S$ ) of 10 k $\Omega$  or more should be connected from this terminal to  $V_{SS}$ . If unused this terminal should be left open. The VCO can be connected either directly or through frequency dividers to the comparator input of the phase comparators. A full CMOS logic swing is available at the output of the VCO and allows direct coupling to CMOS frequency dividers such as the RCA-CD4024, CD4018, CD4020, CD4022, CD4029, and CD4059. One or more CD4018 (Presettable Divide-by-N Counter) or CD4029 (Presettable Up/Down Counter), or CD4059A (Programmable Divide-by-"N" Counter), together with the CD4046A (Phase-Locked Loop) can be used to build a micropower low-frequency synthesizer. A logic 0 on the INHIBIT input "enables" the VCO and the source follower, while a logic 1 "turns off" both to minimize stand-by power consumption.

Phase Comparators

The phase-comparator signal input (terminal 14) can be direct-coupled provided the signal swing is within CMOS logic levels [logic "0"  $\leq 30\%$  ( $V_{DD}-V_{SS}$ ), logic "1"  $\geq 70\%$  ( $V_{DD}-V_{SS}$ )]. For smaller swings the signal must be capacitively coupled to the self-biasing amplifier at the signal input.

Phase comparator I is an exclusive-OR network; it operates analogously to an over-driven balanced mixer. To maximize the lock range, the signal- and comparator-input frequencies must have a 50% duty cycle. With no signal or noise on the signal input, this phase comparator has an average output voltage equal to  $V_{DD}/2$ . The low-pass filter connected to the output of phase comparator I supplies the averaged voltage to the VCO input, and causes the VCO to oscillate at the center frequency ( $f_0$ ).

The frequency range of input signals on which the PLL will lock if it was initially

Features:

- Very low power consumption: 70  $\mu$ W (typ.) at VCO  $f_0 = 10$  kHz,  $V_{DD} = 5$  V
- Operating frequency range up to 1.2 MHz (typ.) at  $V_{DD} = 10$  V
- Wide supply-voltage range:  $V_{DD} - V_{SS} = 5$  to 15 V
- Low frequency drift: 0.06%/°C (typ.) at  $V_{DD} = 10$  V
- Choice of two phase comparators:
  1. Exclusive-OR network
  2. Edge-controlled memory network with phase-pulse output for lock indication
- High VCO linearity: 1% (typ.)
- VCO inhibit control for ON-OFF keying and ultra-low standby power consumption
- Source-follower output of VCO control input (Demod. output)
- Zener diode to assist supply regulation
- Quiescent current specified to 15 V
- Maximum input leakage current of 1  $\mu$ A at 15 V (full package-temperature range)

Applications:

- FM demodulator and modulator
- Frequency synthesis and multiplication
- Frequency discriminator
- Data synchronization
- Voltage-to-frequency conversion
- Tone decoding
- FSK - Modems
- Signal conditioning

out of lock is defined as the frequency capture range ( $2f_c$ ).

The frequency range of input signals on which the loop will stay locked if it was initially in lock is defined as the frequency lock range ( $2f_L$ ). The capture range is  $\leq$  the lock range.

With phase comparator I the range of frequencies over which the PLL can acquire lock (capture range) is dependent on the low-pass-filter characteristics, and can be made as large as the lock range. Phase-com-

parator I enables a PLL system to remain in lock in spite of high amounts of noise in the input signal.

One characteristic of this type of phase comparator is that it may lock onto input frequencies that are close to harmonics of the VCO center-frequency. A second characteristic is that the phase angle between the signal and the comparator input varies between 0° and 180°, and is 90° at the center frequency. Fig. 2 shows the typical, triangular, phase-to-output response characteristic

\* For sine wave, the frequency must be greater than 1 kHz for Phase Comparator II.

of phase-comparator I. Typical waveforms for a CMOS phase-locked-loop employing phase comparator I in locked condition of  $f_o$  is shown in Fig. 3.

Fig. 3 - Typical waveforms for COS/MOS phase-locked loop employing phase comparator I in locked condition of  $f_o$ .

Phase-comparator II is an edge-controlled digital memory network. It consists of four flip-flop stages, control gating, and a three-state output circuit comprising p- and n-type drivers having a common output node. When the p-MOS or n-MOS drivers are ON they pull the output up to  $V_{DD}$  or down to  $V_{SS}$ , respectively. This type of phase-comparator acts only on the positive edges of the signal and comparator inputs. The duty cycles of the signal and comparator inputs are not important since positive transitions control the PLL system utilizing this type of comparator. If the signal-input frequency is higher than the comparator-input frequency, the p-type output driver is maintained ON most of the time, and both the n and p drivers OFF (3 state) the remainder of the time. If the signal-input frequency is lower than the comparator-input frequency, the n-type output driver is maintained ON most of the time, and both the n and p drivers OFF (3 state) the remainder of the time. If the signal- and comparator-input frequencies are the same, but the signal input lags the comparator input in phase, the n-type output driver is maintained ON for a time corresponding to the phase difference. If the signal- and comparator-input frequencies are the same, but the comparator input lags the signal in phase, the p-type output driver is maintained ON for a time corresponding to the phase difference. Subsequently, the capacitor voltage of the low-pass filter connected to this phase comparator is adjusted until the signal and comparator inputs are equal in both phase and frequency. At this stable point both p- and n-type output drivers remain OFF and thus the phase comparator output becomes an open circuit and holds the voltage on the capacitor of the low-pass filter constant.

\* Positive coefficient.

Moreover the signal at the "phase pulses" output is a high level which can be used for indicating a locked condition. Thus, for phase comparator II, no phase difference exists between signal and comparator input over the full VCO frequency range. Moreover, the power dissipation due to the low-pass filter is reduced when this type of phase comparator is used because both the p- and n-type output drivers are OFF for most of the signal input cycle. It should be noted that the PLL lock range for this type of phase comparator is equal to the capture range, independent of the low-pass filter. With no signal present at the signal input, the VCO is adjusted to its lowest frequency for phase comparator II. Fig. 4 shows typical waveforms for a CMOS PLL employing phase comparator II in a locked condition.

**DESIGN INFORMATION**

This information is a guide for approximating the values of external components for the CD4046A in a Phase-Locked-Loop system. The selected external components must be within the following ranges:

$10\text{ k}\Omega \leq R_1, R_2, R_S \leq 1\text{ M}\Omega$   
 $C_1 \geq 100\text{ pF}$  at  $V_{DD} \geq 5\text{ V}$ ;  
 $C_1 \geq 50\text{ pF}$  at  $V_{DD} \geq 10\text{ V}$

In addition to the given design information refer to Fig.5 for  $R_1, R_2$ , and  $C_1$  component selections.

Characteristics	Phase Comparator Used	Design Information
VCO Frequency	1	<b>VCO WITHOUT OFFSET</b> $R_2 = \infty$ 
		<b>VCO WITH OFFSET</b> 
For No Signal Input	1	Same as for No.1
	2	VCO will adjust to center frequency, $f_0$
Frequency Lock Range, $2f_L$	1	$2f_L = \text{full VCO frequency range}$ $2f_L = f_{\text{max}} - f_{\text{min}}$
	2	Same as for No.1
Frequency Capture Range, $2f_C$	1	 $2f_C \approx \frac{1}{\pi} \sqrt{\frac{2\pi f_L}{\tau_1}}$
		For $2f_C$ , see Ref. (2)
Loop Filter Component Selection	1	$f_C = f_L$
		$f_C = f_L$
Phase Angle Between Signal and Comparator	1	$90^\circ$ at center frequency ( $f_0$ ) approximating $0^\circ$ and $180^\circ$ at ends of lock range ( $2f_L$ )
	2	Always $0^\circ$ in lock

Fig.5(a) - Typical center frequency vs  $C_1$  for  $R_1 = 10\text{ k}\Omega$ , and  $1\text{ M}\Omega$  and  $f_0 \sim 1/R_1 C_1$ .

Fig.5(b) - Typical frequency offset vs  $C_1$  for  $R_2 = 10\text{ k}\Omega, 100\text{ k}\Omega$ , and  $1\text{ M}\Omega$ .

NOTE: Lower frequency values are obtainable if larger values of  $C_1$  than shown in Figs. 5(a) and 5(b) are used.

**CD4046A Types**

Fig.5(c) - Typical  $f_{\text{max}}/f_{\text{min}}$  vs  $R_2/R_1$ .

Fig.6(a) - Typical VCO power dissipation at center frequency vs  $R_1$ .

N <sub>1</sub>	1		5	1	

NOTES:

- Refer to Rules for Dimensioning Axial Lead Product Outlines.
- Leads at gauge plane within 0.007" (0.178 mm) radius of True Position (TP) at maximum material condition.
- φB applies between L<sub>1</sub> and L<sub>2</sub>. φB<sub>2</sub> applies between L<sub>2</sub> and 0.500" (12.70 mm) from seating plane. Diameter is uncontrolled in L<sub>1</sub> and beyond 0.500" (12.70 mm).
- Measure from Max. φD.
- N<sub>1</sub> is the quantity of allowable missing leads.
- N is the maximum quantity of lead positions.

NOTES:

- Leads within 0.005" (0.13 mm) radius of True Position at maximum material condition.
- Dimension "L" to center of leads when formed parallel.
- When this device is supplied solder-dipped, the maximum lead thickness (narrow portion) will not exceed 0.013" (0.33 mm).

92CS-24026 R1

NOTES:

Refer to Rules for Dimensioning (JEDEC Publication No. 95) for Axial Lead Product Outlines.

- When this device is supplied solder-dipped, the maximum lead thickness (narrow portion) will not exceed 0.013".
- Leads within 0.005" (0.12 mm) radius of True Position (TP) at gauge plane with maximum material condition and unit installed.
- e<sub>A</sub> applies in zone L<sub>2</sub> when unit installed.
- a applies to spread leads prior to installation.
- N is the maximum quantity of lead positions.
- N<sub>1</sub> is the quantity of allowable missing leads.
