HIGH-SPEED 16K x 16 DUAL-PORT STATIC RAM WITH INTERRUPT

IDT70261S/L

FEATURES:

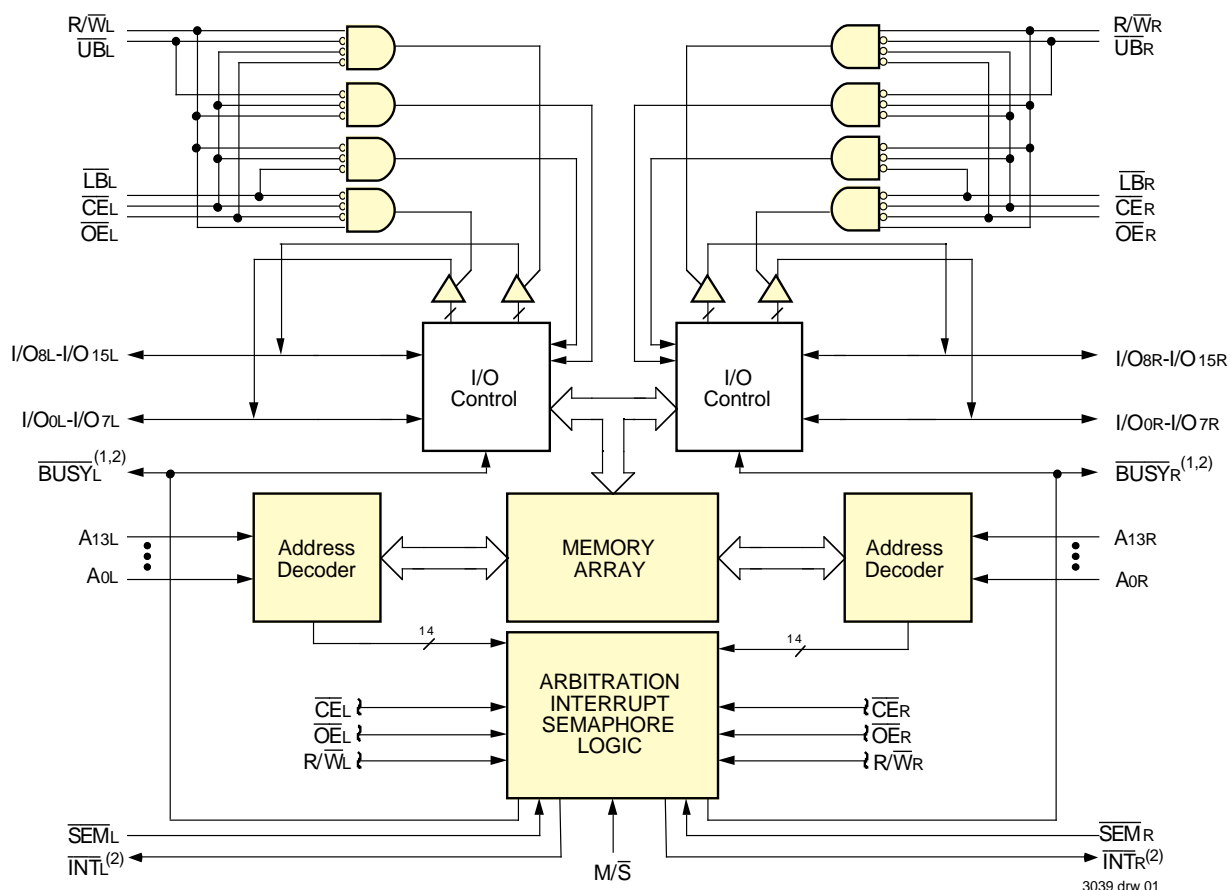

- True Dual-Ported memory cells which allow simultaneous access of the same memory location
- High-speed access
 - Commercial: 20/25/35/55ns (max.)
- Low-power operation
 - IDT70261S
 - Active: 750mW (typ.)
 - Standby: 5mW (typ.)
 - IDT70261L
 - Active: 750mW (typ.)
 - Standby: 1mW (typ.)
- Separate upper-byte and lower-byte control for multiplexed bus compatibility
- IDT70261 easily expands data bus width to 32 bits or more using the Master/Slave select when cascading more than one device

- $M/\overline{S} = H$ for \overline{BUSY} output flag on Master, $M/\overline{S} = L$ for \overline{BUSY} input on Slave
- Busy and Interrupt Flags
- On-chip port arbitration logic
- Full on-chip hardware support of semaphore signaling between ports
- Fully asynchronous operation from either port
- TTL-compatible, single 5V ($\pm 10\%$) power supply
- Available in 100-pin Thin Quad Plastic Flatpack

DESCRIPTION:

The IDT70261 is a high-speed 16K x 16 Dual-Port Static RAM. The IDT70261 is designed to be used as a stand-alone Dual-Port RAM or as a combination MASTER/SLAVE Dual-Port RAM for 32-bit-or-more word systems. Using the IDT MASTER/SLAVE Dual-Port RAM approach in 32-bit or wider memory system applications results in full-speed, error-free

FUNCTIONAL BLOCK DIAGRAM

NOTES:

1. (MASTER): \overline{BUSY} is output; (SLAVE): \overline{BUSY} is input.
2. \overline{BUSY} and \overline{INT} outputs are non-tri-stated push-pull.

The IDT logo is a registered trademark of Integrated Device Technology, Inc.

COMMERCIAL TEMPERATURE RANGE

OCTOBER 1996

operation without the need for additional discrete logic.

This device provides two independent ports with separate control, address, and I/O pins that permit independent, asynchronous access for reads or writes to any location in memory. An automatic power down feature controlled by CE

permits the on-chip circuitry of each port to enter a very low standby power mode.

Fabricated using IDT's CMOS high-performance technology, these devices typically operate on only 750mW of power.

The IDT70261 is packaged in a 100-pin TQFP.

PIN CONFIGURATIONS ^(1,2)

NOTES:

1. All Vcc pins must be connected to power supply.
2. All GND pins must be connected to ground supply.
3. This text does not indicate orientation of the actual part-marking.

PIN NAMES

Left Port	Right Port	Names
\overline{CE}_L	\overline{CE}_R	Chip Enable
R/\overline{WL}	R/\overline{WR}	Read/Write Enable
\overline{OE}_L	\overline{OE}_R	Output Enable
A0L – A13L	A0R – A13R	Address
I/O0L – I/O15L	I/O0R – I/O15R	Data Input/Output
\overline{SEM}_L	\overline{SEM}_R	Semaphore Enable
\overline{UB}_L	\overline{UB}_R	Upper Byte Select
\overline{LB}_L	\overline{LB}_R	Lower Byte Select
\overline{INT}_L	\overline{INT}_R	Interrupt Flag
\overline{BUSY}_L	\overline{BUSY}_R	Busy Flag
M/ \overline{S}		Master or Slave Select
Vcc		Power
GND		Ground

RECOMMENDED OPERATING TEMPERATURE AND SUPPLY VOLTAGE

Grade	Ambient Temperature	GND	Vcc
Commercial	0°C to +70°C	0V	5.0V \pm 10%

3039 tbl 02

TRUTH TABLE I – NON-CONTENTION READ/WRITE CONTROL

Inputs ⁽¹⁾						Outputs		Mode
\overline{CE}	R/W	\overline{OE}	\overline{UB}	\overline{LB}	\overline{SEM}	I/O8-15	I/O0-7	
H	X	X	X	X	H	High-Z	High-Z	Deselected: Power-Down
X	X	X	H	H	H	High-Z	High-Z	Both Bytes Deselected
L	L	X	L	H	H	DATAin	High-Z	Write to Upper Byte Only
L	L	X	H	L	H	High-Z	DATAin	Write to Lower Byte Only
L	L	X	L	L	H	DATAin	DATAin	Write to Both Bytes
L	H	L	L	H	H	DATAout	High-Z	Read Upper Byte Only
L	H	L	H	L	H	High-Z	DATAout	Read Lower Byte Only
L	H	L	L	L	H	DATAout	DATAout	Read Both Bytes
X	X	H	X	X	X	High-Z	High-Z	Outputs Disabled

NOTE:

1. A0L — A13L ≠ A0R — A13R.

3039 tbl 03

TRUTH TABLE II – SEMAPHORE READ/WRITE CONTROL⁽¹⁾

Inputs						Outputs		Mode
\overline{CE}	R/W	\overline{OE}	\overline{UB}	\overline{LB}	\overline{SEM}	I/O8-15	I/O0-7	
H	H	L	X	X	L	DATAout	DATAout	Read Data in Semaphore Flag
X	H	L	H	H	L	DATAout	DATAout	Read Data in Semaphore Flag
H	\nearrow	X	X	X	L	DATAin	DATAin	Write I/O0 into Semaphore Flag
X	\nearrow	X	H	H	L	DATAin	DATAin	Write I/O0 into Semaphore Flag
L	X	X	L	X	L	—	—	Not Allowed
L	X	X	X	L	L	—	—	Not Allowed

NOTE:

1. There are eight semaphore flags written to via I/O0 and read from all I/O's(I/O0 - I/O15). These eight semaphores are addressed by A0 - A2.

3039 tbl 04

ABSOLUTE MAXIMUM RATINGS⁽¹⁾

Symbol	Rating	Commercial	Unit
VTERM ⁽²⁾	Terminal Voltage with Respect to GND	-0.5 to +7.0	V
TA	Operating Temperature	0 to +70	°C
TBIAS	Temperature Under Bias	-55 to +125	°C
TSTG	Storage Temperature	-55 to +125	°C
IOUT	DC Output Current	50	mA

NOTES:

3039 tbl 05

- Stresses greater than those listed under ABSOLUTE MAXIMUM RATINGS may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.
- VTERM must not exceed Vcc + 0.5V for more than 25% of the cycle time or 10ns maximum, and is limited to ≤ 20mA for the period of VTERM ≥ Vcc + 0.5V.

RECOMMENDED DC OPERATING CONDITIONS

Symbol	Parameter	Min.	Typ.	Max.	Unit
VCC	Supply Voltage	4.5	5.0	5.5	V
GND	Supply Voltage	0	0	0	V
VIH	Input High Voltage	2.2	—	6.0 ⁽²⁾	V
VIL	Input Low Voltage	-0.5 ⁽¹⁾	—	0.8	V

NOTES:

3039 tbl 06

- VIL ≥ -1.5V for pulse width less than 10ns.
- VTERM must not exceed Vcc + 0.5V.

CAPACITANCE⁽¹⁾

(TA = +25°C, f = 1.0MHz) TQFP ONLY

Symbol	Parameter	Conditions ⁽²⁾	Max.	Unit
CIN	Input Capacitance	VIN = 3dV	9	pF
COUT	Output Capacitance	VOU = 3dV	10	pF

NOTES:

3039 tbl 07

- This parameter is determined by device characterization but is not production tested.
- 3dV represents the interpolated capacitance when the input and output signals switch from 0V to 3V or from 3V to 0V.

DC ELECTRICAL CHARACTERISTICS OVER THE OPERATING TEMPERATURE AND SUPPLY VOLTAGE RANGE ($V_{CC} = 5.0V \pm 10\%$)

Symbol	Parameter	Test Conditions	IDT70261S		IDT70261L		Unit
			Min.	Max.	Min.	Max.	
$ I_{LI} $	Input Leakage Current ⁽¹⁾	$V_{CC} = 5.5V$, $V_{IN} = 0V$ to V_{CC}	—	10	—	5	μA
$ I_{LO} $	Output Leakage Current	$\overline{CE} = V_{IH}$, $V_{OUT} = 0V$ to V_{CC}	—	10	—	5	μA
V_{OL}	Output Low Voltage	$I_{OL} = 4mA$	—	0.4	—	0.4	V
V_{OH}	Output High Voltage	$I_{OH} = -4mA$	2.4	—	2.4	—	V

NOTE:

1. At $V_{CC} \leq 2.0V$, input leakages are undefined.

NOTES:

1. Transition is measured ± 200 mV from Low or High-impedance voltage with Output Test Load (Figure 2).
2. This parameter is guaranteed by device characterization, but is not production tested.
3. To access RAM, $\overline{CE} = V_{IL}$ and $\overline{SEM} = V_{IH}$. To access semaphore, $\overline{CE} = V_{IH}$ and $\overline{SEM} = V_{IL}$.
4. "X" in part numbers indicates power rating (S or L).

3039 tbl 12

WAVEFORM OF READ CYCLES⁽⁵⁾

NOTES:

1. Timing depends on which signal is asserted last, \overline{OE} , \overline{CE} , \overline{LB} , or \overline{UB} .
2. Timing depends on which signal is de-asserted first \overline{CE} , \overline{OE} , \overline{LB} , or \overline{UB} .
3. t_{BDD} delay is required only in cases where the opposite port is completing a write operation to the same address location. For simultaneous read operations \overline{BUSY} has no relation to valid output data.
4. Start of valid data depends on which timing becomes effective last t_{AOE} , t_{ACE} , t_{AA} or t_{BDD} .
5. $SEM = V_{IH}$.

twZ	Write Enable to Output in High-Z ^(1, 2)	—	15	—	25	ns
tOW	Output Active from End-of-Write ^(1, 2, 4)	0	—	0	—	ns
tSWRD	SEM Flag Write to Read Time	5	—	5	—	ns
tSPS	SEM Flag Contention Window	5	—	5	—	ns

NOTES:

1. Transition is measured $\pm 200\text{mV}$ from Low or High-impedance voltage with Output Test Load (Figure 2).
2. This parameter is guaranteed by device characterization, but is not production tested.
3. To access RAM, $\text{CE} = \text{V}_{\text{IL}}$ and $\overline{\text{SEM}} = \text{V}_{\text{IH}}$. To access semaphore, $\text{CE} = \text{V}_{\text{IH}}$ and $\overline{\text{SEM}} = \text{V}_{\text{IL}}$. Either condition must be valid for the entire tEW time.
4. The specification for tDH must be met by the device supplying write data to the RAM under all operating conditions. Although tDH and tOW values will vary over voltage and temperature, the actual tDH will always be smaller than the actual tOW.
5. "X" in part numbers indicates power rating (S or L).

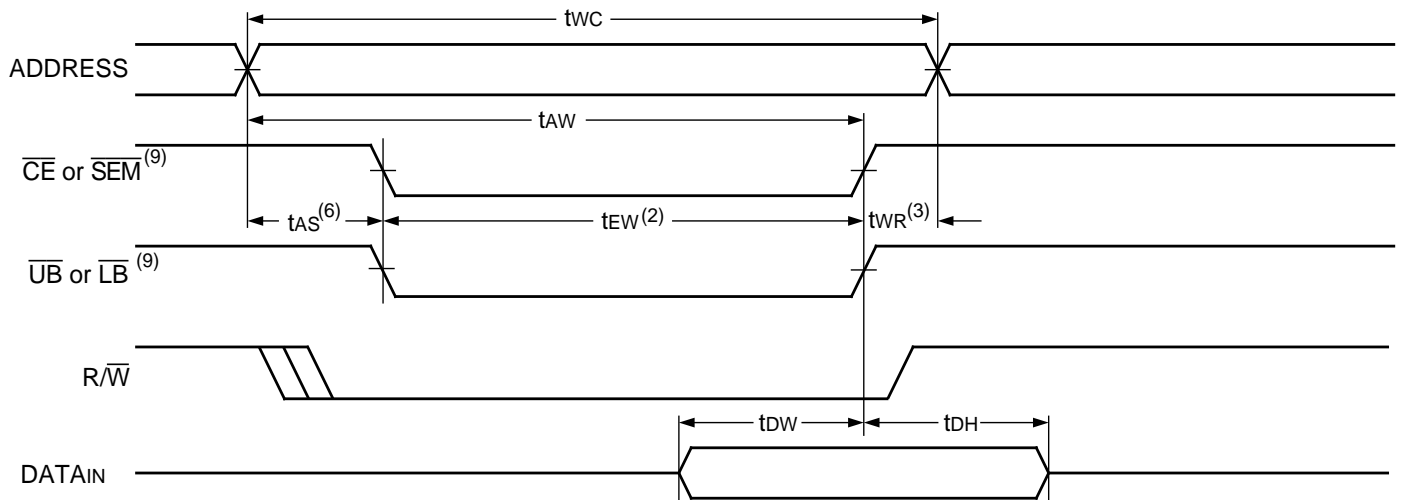

3039 tbl 13

TIMING WAVEFORM OF WRITE CYCLE NO. 1, $\overline{R/\overline{W}}$ CONTROLLED TIMING^(1,5,8)

3039 drw 07

TIMING WAVEFORM OF WRITE CYCLE NO. 2, \overline{CE} , \overline{UB} , \overline{LB} CONTROLLED TIMING^(1,5)

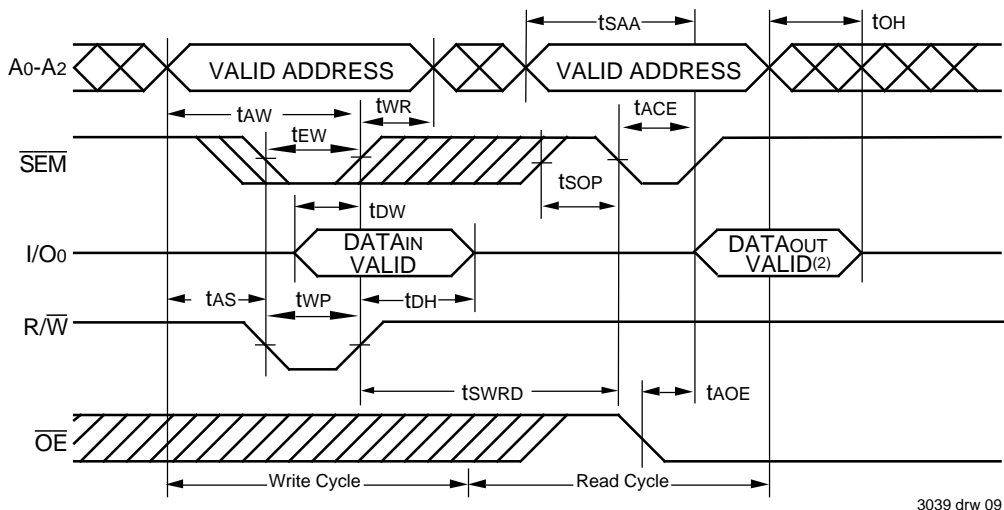

3039 drw 08

NOTES:

1. $\overline{R/\overline{W}}$ or \overline{CE} or \overline{UB} and \overline{LB} must be HIGH during all address transitions.
2. A write occurs during the overlap (t_{EW} or t_{WP}) of a LOW \overline{CE} and a LOW $\overline{R/\overline{W}}$ for memory array writing cycle.
3. t_{WR} is measured from the earlier of \overline{CE} or $\overline{R/\overline{W}}$ (or \overline{SEM} or $\overline{R/\overline{W}}$) going HIGH to the end of write cycle.
4. During this period, the I/O pins are in the output state and input signals must not be applied.
5. If the \overline{CE} or \overline{SEM} LOW transition occurs simultaneously with or after the $\overline{R/\overline{W}}$ LOW transition, the outputs remain in the High-impedance state.
6. Timing depends on which enable signal is asserted last, \overline{CE} or $\overline{R/\overline{W}}$.
7. This parameter is guaranteed by device characterization, but is not production tested. Transition is measured $\pm 200\text{mV}$ from steady state with the Output Test Load (Figure 2).
8. If \overline{OE} is LOW during $\overline{R/\overline{W}}$ controlled write cycle, the write pulse width must be the larger of t_{WP} or $(t_{WZ} + t_{OW})$ to allow the I/O drivers to turn off and data to be placed on the bus for the required t_{DW} . If \overline{OE} is HIGH during an $\overline{R/\overline{W}}$ controlled write cycle, this requirement does not apply and the write pulse can be as short as the specified t_{WP} .
9. To access RAM, $\overline{CE} = V_{IL}$ and $\overline{SEM} = V_{IH}$. To access semaphore, $\overline{CE} = V_{IH}$ and $\overline{SEM} = V_{IL}$. t_{EW} must be met for either condition.

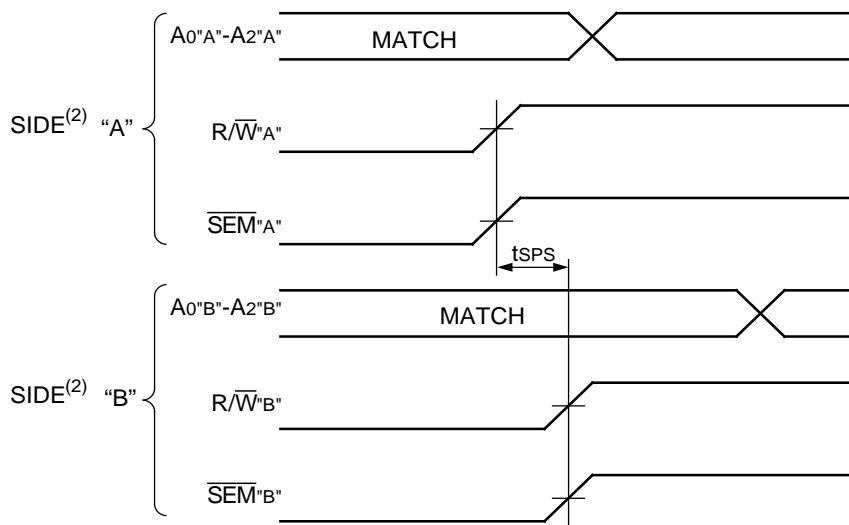

TIMING WAVEFORM OF SEMAPHORE READ AFTER WRITE TIMING, EITHER SIDE⁽¹⁾

NOTES:

1. $\overline{CE} = V_{IH}$ or $\overline{UB} = V_{IH}$ for the duration of the above timing (both write and read cycle).
2. "DATAout VALID" represents all I/O's (I/O₀-I/O₁₅) equal to the semaphore value.

TIMING WAVEFORM OF SEMAPHORE WRITE CONTENTION^(1,3,4)

NOTES:

1. $DOR = DOL = V_{IL}$, $\overline{CE}_R = \overline{CE}_L = V_{IH}$, or both $\overline{UB} \& \overline{LB} = V_{IH}$.
2. All timing is the same for left and right ports. Port "A" may be either left or right port. Port "B" is the opposite from port "A".
3. This parameter is measured from R/\overline{W}^A or \overline{SEM}^A going HIGH to R/\overline{W}^B or \overline{SEM}^B going HIGH.
4. If tSPS is not satisfied, there is no guarantee which side will be granted the semaphore flag.

tDDD	Write Data Valid to Read Data Delay ⁽¹⁾	—	45	—	65	ns

NOTES:

- Port-to-port delay through RAM cells from writing port to reading port, refer to "Timing Wave form of Write with Port-to-Port Read and \bar{BUSY} ($M/\bar{S} = V_{IH}$)".
- To ensure that the earlier of the two ports wins.
- tBDD is a calculated parameter and is the greater of 0, twDD – twP (actual), or tDDD – tDW (actual).
- To ensure that the write cycle is inhibited on port "B" during contention on port "A".
- To ensure that a write cycle is completed on port "B" after contention on port "A".
- "X" in part numbers indicates power rating (S or L).

3039 tbl 14

TIMING WAVEFORM OF WRITE WITH PORT-TO-PORT READ AND \overline{BUSY} ($M/\overline{S} = V_{IH}$)^(2,4,5)

3039 drw 11

NOTES:

1. To ensure that the earlier of the two ports wins. tAPS is ignored for $M/\overline{S} = V_{IL}$ (SLAVE).
2. $\overline{CE_L} = \overline{CE_R} = V_{IL}$.
3. $\overline{OE} = V_{IL}$ for the reading port.
4. If $M/\overline{S} = V_{IL}$ (slave), \overline{BUSY} is an input. Then for this example $\overline{BUSY}^A = V_{IH}$ and \overline{BUSY}^B input is shown above.
5. All timing is the same for left and right ports. Port "A" may be either the left or right port. Port "B" is the port opposite from port "A".

TIMING WAVEFORM OF WRITE WITH \overline{BUSY} ($M/\overline{S} = V_{IL}$)

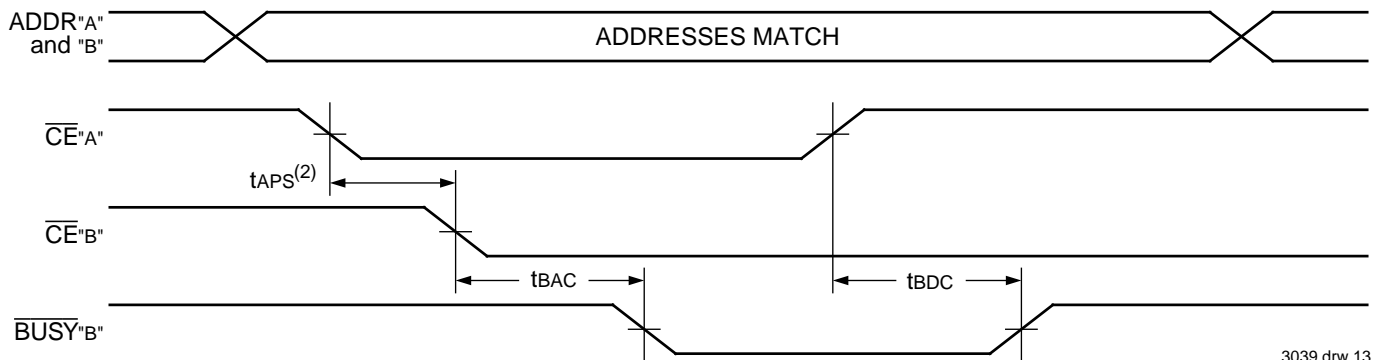

3039 drw 12

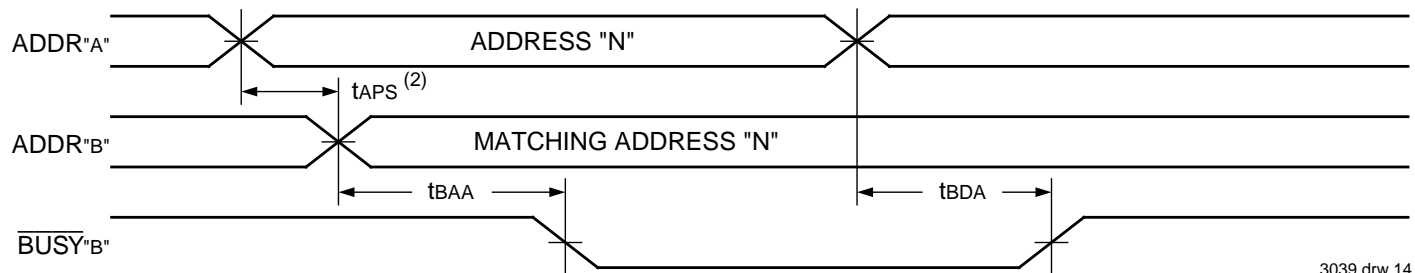

NOTES:

1. tWH must be met for both \overline{BUSY} input (SLAVE) and output (MASTER).
2. \overline{BUSY} is asserted on port "B" blocking R/\overline{W}^B , until \overline{BUSY}^B goes High.

WAVEFORM OF $\overline{\text{BUSY}}$ ARBITRATION CONTROLLED BY $\overline{\text{CE}}$ TIMING ($M/\overline{\text{S}} = V_{IH}$)⁽¹⁾

WAVEFORM OF BUSY ARBITRATION CYCLE CONTROLLED BY ADDRESS MATCH TIMING ($M/\overline{\text{S}} = V_{IH}$)⁽¹⁾

NOTES:

1. All timing is the same for left and right ports. Port "A" may be either the left or right port. Port "B" is the port opposite from port "A".
2. If t_{APS} is not satisfied, the busy signal will be asserted on one side or another but there is no guarantee on which side busy will be asserted.

X	X	NO MATCH	H	H	Normal
H	X	MATCH	H	H	Normal
X	H	MATCH	H	H	Normal
L	L	MATCH	(2)	(2)	Write Inhibit ⁽³⁾

NOTES:

2683 tbl 17

1. Pins $\overline{BUSY_L}$ and $\overline{BUSY_R}$ are both outputs when the part is configured as a master. Both are inputs when configured as a slave. \overline{BUSY} outputs on the IDT70261 are push-pull, not open drain outputs. On slaves the \overline{BUSY} input internally inhibits writes.
2. "L" if the inputs to the opposite port were stable prior to the address and enable inputs of this port. "H" if the inputs to the opposite port became stable after the address and enable inputs of this port. If taps is not met, either $\overline{BUSY_L}$ or $\overline{BUSY_R}$ = LOW will result. $\overline{BUSY_L}$ and $\overline{BUSY_R}$ outputs can not be LOW simultaneously.
3. Writes to the left port are internally ignored when $\overline{BUSY_L}$ outputs are driving LOW regardless of actual logic level on the pin. Writes to the right port are internally ignored when $\overline{BUSY_R}$ outputs are driving LOW regardless of actual logic level on the pin.

TRUTH TABLE V — EXAMPLE OF SEMAPHORE PROCUREMENT SEQUENCE^(1,2)

NOTES:

2683 tbl 18

1. This table denotes a sequence of events for only one of the eight semaphores on the IDT70261.
2. There are eight semaphore flags written to via I/O₀ and read from all I/O's (I/O₀-I/O₁₅). These eight semaphores are addressed by A₀ - A₇.

FUNCTIONAL DESCRIPTION

The IDT70261 provides two ports with separate control, address and I/O pins that permit independent access for reads or writes to any location in memory. The IDT70261 has an automatic power down feature controlled by \overline{CE} . The \overline{CE} controls on-chip power down circuitry that permits the respective port to go into a standby mode when not selected (\overline{CE} HIGH). When a port is enabled, access to the entire memory array is permitted.

INTERRUPTS

If the user chooses to use the interrupt function, a memory location (mail box or message center) is assigned to each port. The left port interrupt flag ($\overline{INT_L}$) is asserted when the right port writes to memory location 3FFE (HEX), where a write is defined as $\overline{CE} = R/\overline{W} = V_{IL}$ per the Truth Table. The left port clears the interrupt through access of address location 3FFE when $\overline{CER} = \overline{OER} = V_{IL}$, R/\overline{W} is a "don't care". Likewise, the right port interrupt flag ($\overline{INT_R}$) is asserted when the left port writes to memory location 3FFF (HEX) and to clear the

interrupt flag ($\overline{INT_R}$), the right port must read the memory location 3FFF. The message (16 bits) at 3FFE or 3FFF is user-defined since it is an addressable SRAM location. If the interrupt function is not used, address locations 3FFE and 3FFF are not used as mail boxes, but as part of the random access memory. Refer to Truth Table for the interrupt operation.

BUSY LOGIC

Busy Logic provides a hardware indication that both ports of the RAM have accessed the same location at the same time. It also allows one of the two accesses to proceed and signals the other side that the RAM is "Busy". The busy pin can then be used to stall the access until the operation on the other side is completed. If a write operation has been attempted from the side that receives a busy indication, the write signal is gated internally to prevent the write from proceeding.

The use of busy logic is not required or desirable for all applications. In some cases it may be useful to logically OR the busy outputs together and use any busy indication as an

interrupt source to flag the event of an illegal or illogical operation. If the write inhibit function of busy logic is not desirable, the busy logic can be disabled by placing the part in slave mode with the $\overline{M/\overline{S}}$ pin. Once in slave mode the \overline{BUSY} pin operates solely as a write inhibit input pin. Normal operation can be programmed by tying the \overline{BUSY} pins high. If desired, unintended write operations can be prevented to a port by tying the busy pin for that port low.

The busy outputs on the IDT 70261 RAM in master mode, are push-pull type outputs and do not require pull up resistors to operate. If these RAMs are being expanded in depth, then the busy indication for the resulting array requires the use of an external AND gate.

WIDTH EXPANSION WITH BUSY LOGIC MASTER/SLAVE ARRAYS

When expanding an IDT70261 RAM array in width while using busy logic, one master part is used to decide which side of the RAM array will receive a busy indication, and to output that indication. Any number of slaves to be addressed in the

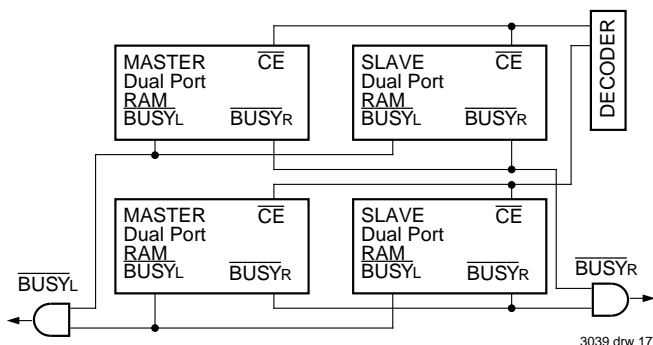

Figure 3. Busy and chip enable routing for both width and depth expansion with IDT70261 RAMs.

same address range as the master, use the busy signal as a write inhibit signal. Thus on the IDT70261 RAM the busy pin is an output if the part is used as a master ($\overline{M/\overline{S}}$ pin = H), and the busy pin is an input if the part used as a slave ($\overline{M/\overline{S}}$ pin = L) as shown in Figure 3.

If two or more master parts were used when expanding in width, a split decision could result with one master indicating busy on one side of the array and another master indicating busy on one other side of the array. This would inhibit the write operations from one port for part of a word and inhibit the write operations from the other port for the other part of the word.

The busy arbitration, on a master, is based on the chip enable and address signals only. It ignores whether an access is a read or write. In a master/slave array, both address and chip enable must be valid long enough for a busy flag to be output from the master before the actual write pulse can be initiated with either the $\overline{R/\overline{W}}$ signal or the byte enables. Failure to observe this timing can result in a glitched internal write inhibit signal and corrupted data in the slave.

SEMAPHORES

The IDT70261 is an extremely fast Dual-Port 16K x 16

CMOS Static RAM with an additional 8 address locations dedicated to binary semaphore flags. These flags allow either processor on the left or right side of the Dual-Port RAM to claim a privilege over the other processor for functions defined by the system designer's software. As an example, the semaphore can be used by one processor to inhibit the other from accessing a portion of the Dual-Port RAM or any other shared resource.

The Dual-Port RAM features a fast access time, and both ports are completely independent of each other. This means that the activity on the left port in no way slows the access time of the right port. Both ports are identical in function to standard CMOS Static RAM and can be read from, or written to, at the same time with the only possible conflict arising from the simultaneous writing of, or a simultaneous READ/WRITE of, a non-semaphore location. Semaphores are protected against such ambiguous situations and may be used by the system program to avoid any conflicts in the non-semaphore portion of the Dual-Port RAM. These devices have an automatic power-down feature controlled by \overline{CE} , the Dual-Port RAM enable, and \overline{SEM} , the semaphore enable. The \overline{CE} and \overline{SEM} pins control on-chip power down circuitry that permits the respective port to go into standby mode when not selected. This is the condition which is shown in Truth Table where \overline{CE} and \overline{SEM} are both high.

Systems which can best use the IDT70261 contain multiple processors or controllers and are typically very high-speed systems which are software controlled or software intensive. These systems can benefit from a performance increase offered by the IDT70261's hardware semaphores, which provide a lockout mechanism without requiring complex programming.

Software handshaking between processors offers the maximum in system flexibility by permitting shared resources to be allocated in varying configurations. The IDT70261 does not use its semaphore flags to control any resources through hardware, thus allowing the system designer total flexibility in system architecture.

An advantage of using semaphores rather than the more common methods of hardware arbitration is that wait states are never incurred in either processor. This can prove to be a major advantage in very high-speed systems.

HOW THE SEMAPHORE FLAGS WORK

The semaphore logic is a set of eight latches which are independent of the Dual-Port RAM. These latches can be used to pass a flag, or token, from one port to the other to indicate that a shared resource is in use. The semaphores provide a hardware assist for a use assignment method called "Token Passing Allocation." In this method, the state of a semaphore latch is used as a token indicating that shared resource is in use. If the left processor wants to use this resource, it requests the token by setting the latch. This processor then verifies its success in setting the latch by reading it. If it was successful, it proceeds to assume control over the shared resource. If it was not successful in setting the latch, it determines that the right side processor has set the

latch first, has the token and is using the shared resource. The left processor can then either repeatedly request that semaphore's status or remove its request for that semaphore to perform another task and occasionally attempt again to gain control of the token via the set and test sequence. Once the right side has relinquished the token, the left side should succeed in gaining control.

The semaphore flags are active low. A token is requested by writing a zero into a semaphore latch and is released when the same side writes a one to that latch.

The eight semaphore flags reside within the IDT70261 in a separate memory space from the Dual-Port RAM. This address space is accessed by placing a low input on the $\overline{\text{SEM}}$ pin (which acts as a chip select for the semaphore flags) and using the other control pins (Address, $\overline{\text{OE}}$, and $\text{R}/\overline{\text{W}}$) as they would be used in accessing a standard Static RAM. Each of the flags has a unique address which can be accessed by either side through address pins A0–A2. When accessing the semaphores, none of the other address pins has any effect.

When writing to a semaphore, only data pin D0 is used. If a low level is written into an unused semaphore location, that flag will be set to a zero on that side and a one on the other side (see Table III). That semaphore can now only be modified by the side showing the zero. When a one is written into the same location from the same side, the flag will be set to a one for both sides (unless a semaphore request from the other side is pending) and then can be written to by both sides. The fact that the side which is able to write a zero into a semaphore subsequently locks out writes from the other side is what makes semaphore flags useful in interprocessor communications. (A thorough discussing on the use of this feature follows shortly.) A zero written into the same location from the other side will be stored in the semaphore request latch for that side until the semaphore is freed by the first side.

When a semaphore flag is read, its value is spread into all data bits so that a flag that is a one reads as a one in all data bits and a flag containing a zero reads as all zeros. The read value is latched into one side's output register when that side's semaphore select ($\overline{\text{SEM}}$) and output enable ($\overline{\text{OE}}$) signals go active. This serves to disallow the semaphore from changing state in the middle of a read cycle due to a write cycle from the other side. Because of this latch, a repeated read of a semaphore in a test loop must cause either signal ($\overline{\text{SEM}}$ or $\overline{\text{OE}}$) to go inactive or the output will never change.

A sequence WRITE/READ must be used by the semaphore in order to guarantee that no system level contention will occur. A processor requests access to shared resources by attempting to write a zero into a semaphore location. If the semaphore is already in use, the semaphore request latch will contain a zero, yet the semaphore flag will appear as one, a fact which the processor will verify by the subsequent read (see Table III). As an example, assume a processor writes a zero to the left port at a free semaphore location. On a subsequent read, the processor will verify that it has written successfully to that location and will assume control over the resource in question. Meanwhile, if a processor on the right side attempts to write a zero to the same semaphore flag it will

fail, as will be verified by the fact that a one will be read from that semaphore on the right side during subsequent read. Had a sequence of READ/WRITE been used instead, system contention problems could have occurred during the gap between the read and write cycles.

3039 drw 18

Figure 4. IDT70261 Semaphore Logic

It is important to note that a failed semaphore request must be followed by either repeated reads or by writing a one into the same location. The reason for this is easily understood by looking at the simple logic diagram of the semaphore flag in Figure 4. Two semaphore request latches feed into a semaphore flag. Whichever latch is first to present a zero to the semaphore flag will force its side of the semaphore flag low and the other side high. This condition will continue until a one is written to the same semaphore request latch. Should the other side's semaphore request latch have been written to a zero in the meantime, the semaphore flag will flip over to the other side as soon as a one is written into the first side's request latch. The second side's flag will now stay low until its semaphore request latch is written to a one. From this it is easy to understand that, if a semaphore is requested and the processor which requested it no longer needs the resource, the entire system can hang up until a one is written into that semaphore request latch.

The critical case of semaphore timing is when both sides request a single token by attempting to write a zero into it at the same time. The semaphore logic is specially designed to resolve this problem. If simultaneous requests are made, the logic guarantees that only one side receives the token. If one side is earlier than the other in making the request, the first side to make the request will receive the token. If both requests arrive at the same time, the assignment will be arbitrarily made to one port or the other.

One caution that should be noted when using semaphores is that semaphores alone do not guarantee that access to a resource is secure. As with any powerful programming technique, if semaphores are misused or misinterpreted, a software error can easily happen.

Initialization of the semaphores is not automatic and must be handled via the initialization program at power-up. Since any semaphore request flag which contains a zero must be reset to a one, all semaphores on both sides should have a one written into them at initialization from both sides to assure

that they will be free when needed.

USING SEMAPHORES—SOME EXAMPLES

Perhaps the simplest application of semaphores is their application as resource markers for the IDT70261's Dual-Port RAM. Say the 16K x 16 RAM was to be divided into two 8K x 16 blocks which were to be dedicated at any one time to servicing either the left or right port. Semaphore 0 could be used to indicate the side which would control the lower section of memory, and Semaphore 1 could be defined as the indicator for the upper section of memory.

To take a resource, in this example the lower 8K of Dual-Port RAM, the processor on the left port could write and then read a zero in to Semaphore 0. If this task were successfully completed (a zero was read back rather than a one), the left processor would assume control of the lower 8K. Meanwhile the right processor was attempting to gain control of the resource after the left processor, it would read back a one in response to the zero it had attempted to write into Semaphore 0. At this point, the software could choose to try and gain control of the second 8K section by writing, then reading a zero into Semaphore 1. If it succeeded in gaining control, it would lock out the left side.

Once the left side was finished with its task, it would write a one to Semaphore 0 and may then try to gain access to Semaphore 1. If Semaphore 1 was still occupied by the right side, the left side could undo its semaphore request and perform other tasks until it was able to write, then read a zero into Semaphore 1. If the right processor performs a similar task with Semaphore 0, this protocol would allow the two processors to swap 8K blocks of Dual-Port RAM with each other.

The blocks do not have to be any particular size and can

even be variable, depending upon the complexity of the software using the semaphore flags. All eight semaphores could be used to divide the Dual-Port RAM or other shared resources into eight parts. Semaphores can even be assigned different meanings on different sides rather than being given a common meaning as was shown in the example above.

Semaphores are a useful form of arbitration in systems like disk interfaces where the CPU must be locked out of a section of memory during a transfer and the I/O device cannot tolerate any wait states. With the use of semaphores, once the two devices has determined which memory area was "off-limits" to the CPU, both the CPU and the I/O devices could access their assigned portions of memory continuously without any wait states.

Semaphores are also useful in applications where no memory "WAIT" state is available on one or both sides. Once a semaphore handshake has been performed, both processors can access their assigned RAM segments at full speed.

Another application is in the area of complex data structures. In this case, block arbitration is very important. For this application one processor may be responsible for building and updating a data structure. The other processor then reads and interprets that data structure. If the interpreting processor reads an incomplete data structure, a major error condition may exist. Therefore, some sort of arbitration must be used between the two different processors. The building processor arbitrates for the block, locks it and then is able to go in and update the data structure. When the update is completed, the data structure block is released. This allows the interpreting processor to come back and read the complete data structure, thereby guaranteeing a consistent data structure.
