

Multichip module for TMC tuner applications

Features

- High-performance FM receiver
- SW-Controlled world tuning
- Variable bandwidth IF filter (ISS, intelligent selectivity system)
- Programmable quality detectors
- High-speed PLL for RDS operation
- Full electronic alignment
- High-performance fully digital RDS/RBDS demodulator
- Integrated group and block synchronization
- Error detection and correction
- Full I²C-Bus control

Description

The TDA7546 multichip module combines in a single compact (14X14mm) 80-pin package the functionalities of a state-of-the-art FM receiver and RDS processor, exploiting one single 10.25MHz crystal reference.

The following two devices are included

- **TDA7512F**, high performance car-radio FM tuner with high-speed on-chip PLL and variable-bandwidth IF filter (ISS)
- **TDA7333N**, fully digital RDS data decoder with with on-chip group and block synchronization and error detection/correction.

Both chips are I²C-bus controlled.

Order codes

| Part number | Package | Packing |
|-------------|---------|----------------|
| TDA7546 | LQFP80 | Tray |
| TDA7546TR | LQFP80 | in Tape & Reel |

4 Applications and test circuit

Figure 3. Applications and test circuit

5 Functional description

5.1 Tuner

5.1.1 Mixer1, AGC and 1.IF

The FM quadrature I/Q-mixer converts RF to IF1 of 10.7MHz. The mixer provides inherent image rejection and wide dynamic range with low noise and large input signal performance. The mixer1 tank can be adjusted by software (IF1T). For accurate image rejection the gain- and phase-error generated as well in mixer as VCO stage can be compensated by software (G,PH)

It is capable of tuning the US FM, US weather, Europe FM, Japan FM and East Europe FM bands

- US FM = 87.9 to 107.9 MHz
- US weather = 162.4 to 162.55 MHz
- Europe FM = 87.5 to 108 MHz
- Japan FM = 76 to 91 MHz
- East Europe FM = 65.8 to 74 MHz

The AGC operates on different sensitivities and bandwidths in order to improve the input sensitivity and dynamic range. AGC thresholds are programmable by software (RFAGC,IFAGC,KAGC). The output signal is a controlled current for double pin diode attenuator. Two 10.7MHz programmable amplifiers (IFG1, IFG2) correct the IF ceramic insertion loss and the costumer level plan application.

5.1.2 Mixer2, limiter and demodulator

In this 2. mixer stage the first 10.7MHz IF is converted into the second 450KHz IF. A multi-stage limiter generates signals for the complete integrated demodulator without external tank. MPX output DC offset versus noise DC level is correctable by software (DEM).

5.1.3 Quality detection and ISS

Fieldstrength

Parallel to mixer2 input a 10.7MHz limiter generates a signal for digital IF counter and a fieldstrength output signal. This internal unweighted fieldstrength is used for keying AGC, adjacent channel and multipath detection and is available at PIN14 (FSU) after +6dB buffer stage. The behaviour of this output signal can be corrected for DC offset (SL) and slope (SMSL). The internal generated unweighted fieldstrength is filtered at PIN35 and used for softmute function and generation of ISS filter switching signal for weak input level (sm).

Adjacent channel detector

The input of the adjacent channel detector is AC coupled from internal unweighted fieldstrength. A programmable highpass or bandpass (ACF) and amplifier (ACG) as well as rectifier determines the influences. This voltage is compared with adjustable comparator1 thresholds (ACWTH, ACNTH). The output signal of this comparator generates a DC level at PIN15 by programmable time constant. Time control (TISS) for a present adjacent channel is made by charge and discharge current after comparator1 in an external capacitance. The

charge current is fixed and the discharge current is controlled by I²C Bus. This level produces digital signals (ac, ac+) in an additional comparator⁴. The adjacent channel information is available as analog output signal after rectifier and +8dB output buffer.

Multipath detector

The input of the multipath detector is AC coupled from internal unweighted fieldstrength. A programmable bandpass (MPF) and amplifier (MPG) as well as rectifier determines the influences. This voltage is compared with an adjustable comparator² thresholds (MP_{TH}). The output signal of this comparator² is used for the "Milano" effect. In this case the adjacent channel detection is switched off. The "Milano" effect is selectable by I²C Bus (MPOFF). The multipath information is available as analog output signal after rectifier and +8dB output buffer.

450KHz IF narrow bandpass filter (ISS filter)

The device gets an additional second IF narrow bandpass filter for suppression of noise and adjacent channel influences. This narrow filter has three switchable bandwidths, narrow range of 80KHz, mid range of 120KHz and 30KHz for weather band information.

Without ISS filter the IF bandwidth (wide range) is defined only by ceramic filter chain. The filter is switched in after mixer² before 450KHz limiter stage. The centre frequency is matching to the demodulator center frequency.

Deviation detector

In order to avoid distortion in audio output signal the narrow ISS filter is switched OFF for present overdeviation. Hence the demodulator output signal is detected.

A lowpass filtering and peak rectifier generates a signal that is defined by software controlled current (TDEV) in an external capacitance. This value is compared with a programmable comparator³ thresholds (DW_{TH}, D_{TH}) and generates two digital signals (dev, dev+). For weak signal condition deviation threshold is proportional to FSU.

ISS switch logic

All digital signals coming from adjacent channel detector, deviation detector and softmute are acting via switching matrix on ISS filter switch. The IF bandpass switch mode is controlled by software (ISSON, ISS30, ISS80, CTLOFF).

The switch ON of the IF bandpass is also available by external manipulation of the voltage at PIN15.

Two application modes are available (APPM). The conditions are described in [Table 50](#).

5.1.4 PLL and IF counter section

PLL frequency synthesizer block

This part contains a frequency synthesizer and a loop filter for the radio tuning system. Only one VCO is required to build a complete PLL system for FM world tuning. For auto search stop operation an IF counter system is available.

The counter works in a two stages configuration. The first stage is a swallow counter with a two modulus (32/33) precounter. The second stage is an 11-bit programmable counter.

The circuit receives the scaling factors for the programmable counters and the values of the reference frequencies via an I²C-Bus interface. The reference frequency is generated by an adjustable internal (XTAL) oscillator followed by the reference divider. The main reference and step-frequencies are free selectable (RC, PC).

Output signals of the phase detector are switching the programmable current sources. The loop filter integrates their currents to a DC voltage.

The values of the current sources are programmable by 6 bits also received via the I²C Bus (A, B, CURRH).

To minimize the noise induced by the digital part of the system, a special guard configuration is implemented. The loop gain can be set for different conditions by setting the current values of the chargepump generator.

Frequency generation for phase comparison

The RF signals applies a two modulus counter (32/33) pre-scaler, which is controlled by a 5-bit A-divider. The 5-bit register (PC0 to PC4) controls this divider. In parallel the output of the prescaler connects to an 11-bit B-divider. The 11-bit PC register (PC5 to PC15) controls this divider

Dividing range:

$$f_{VCO} = [33 \times A + (B + 1 - A) \times 32] \times f_{REF}$$

$$f_{VCO} = (32 \times B + A + 32) \times f_{REF}$$

Important: For correct operation: $A \leq 32$; $B \geq A$

Three state phase comparator

The phase comparator generates a phase error signal according to phase difference between f_{SYN} and f_{REF} . This phase error signal drives the charge pump current generator.

Charge pump current generator

This system generates signed pulses of current. The phase error signal decides the duration and polarity of those pulses. The current absolute values are programmable by A register for high current and B register for low current.

Inlock detector

Switching the chargepump in low current mode can be done either via software or automatically by the inlock detector, by setting bit LDENA to "1".

After reaching a phase difference about lower than 40nsec the chargepump is forced in low current mode. A new PLL divider alternation by I²C-Bus will switch the chargepump in the high current mode.

Low noise CMOS op-amp

An internal voltage divider at pin VREF2 connects the positive input of the low noise op-amp. The charge pump output connects the negative input. This internal amplifier in cooperation with external components can provide an active filter.

While the high current mode is activated LPHC output is switched on.

IF counter block

The aim of IF counter is to measure the intermediate frequency of the tuner. The input signal is the 10.7MHz IF level after limiter.

The grade of integration is adjustable by eight different measuring cycle times. The tolerance of the accepted count value is adjustable, to reach an optimum compromise for search speed and precision of the evaluation.

Sampling timer

A sampling timer generates the gate signal for the main counter. The basically sampling time are in FM mode 6.25KHz ($t_{TIM}=160\mu s$).

This is followed by an asynchronous divider to generate several sampling times.

Intermediate frequency main counter

This counter is a 11 - 21-bit synchronous autoreload down counter. Five bits (CF) are programmable to have the possibility for an adjust to the centre frequency of the IF-filter. The counter length is automatic adjusted to the chosen sampling time.

At the start the counter will be loaded with a defined value which is an equivalent to the divider value ($t_{Sample} \times f_{IF}$).

If a correct frequency is applied to the IF counter frequency input at the end of the sampling time the main counter is changing its state from 0h to 1FFFFFFh.

This is detected by a control logic and an external search stop output is changing from LOW to HIGH. The frequency range inside which a successful count result is adjustable by the EW bits.

$$CNT = \frac{CF + 1696}{f_{IF}}$$

Counter result succeeded:

$$t_{TIM} \geq t_{CNT} - t_{ERR}$$

$$t_{TIM} \leq t_{CNT} + t_{ERR}$$

Counter result failed:

$$t_{TIM} > t_{CNT} + t_{ERR}$$

$$t_{TIM} < t_{CNT} - t_{ERR}$$

t_{TIM} = IF timer cycle time (sampling time)

t_{CNT} = IF counter cycle time

t_{ERR} = discrimination window (controlled by the EW registers)

The IF counter is only started by inlock information from the PLL part. It is enabled by software (IFENA).

Adjustment of the measurement sequence time

The precision of the measurements is adjustable by controlling the discrimination window. This is adjustable by programming the control registers EW.

The measurement time per cycle is adjustable by setting the registers IFS.

Adjust of the frequency value

The center frequency of the discrimination window is adjustable by the control registers CF.

5.1.5 I²C-bus interface

The TDA7512F supports the I²C-Bus protocol. This protocol defines any device that sends data onto the bus as a transmitter, and the receiving device as the receiver. The device that controls the transfer is a master and device being controlled is the slave. The master will always initiate data transfer and provide the clock to transmit or receive operations.

Data transition

Data transition on the SDA line must only occur when the clock SCL is LOW. SDA transitions while SCL is HIGH will be interpreted as START or STOP condition.

Start condition

A start condition is defined by a HIGH to LOW transition of the SDA line while SCL is at a stable HIGH level. This "START" condition must precede any command and initiate a data transfer onto the bus.

The device continuously monitors the SDA and SCL lines for a valid START and will not respond to any command if this condition has not been met.

Stop condition

A STOP condition is defined by a LOW to HIGH transition of the SDA while the SCL line is at a stable HIGH level. This condition terminates the communication between the devices and forces the bus-interface of the device into the initial condition.

Acknowledge

Indicates a successful data transfer. The transmitter will release the bus after sending 8 bits of data. During the 9th clock cycle the receiver will pull the SDA line to LOW level to indicate it receive the eight bits of data.

Data transfer

During data transfer the device samples the SDA line on the leading edge of the SCL clock. Therefore, for proper device operation the SDA line must be stable during the SCL LOW to HIGH transition.

Device addressing

To start the communication between two devices, the bus master must initiate a start instruction sequence, followed by an eight bit word corresponding to the address of the device it is addressing.

The most significant 6 bits of the slave address are the device type identifier.

The TDA7512F device type is fixed as "110001".

The next significant bit is used to address a particular device of the previous defined type connected to the bus.

The state of the hardwired PIN 41 defines the state of this address bit. So up to two devices could be connected on the same bus. When PIN 41 is connected to VCC2 the address bit "1" is selected. When PIN 41 is left open the address bit "0" is selected. Therefore a double FM tuner concept is possible.

The last bit of the start instruction defines the type of operation to be performed:

- When set to "1", a read operation is selected
- When set to "0", a write operation is selected

The TDA7512F connected to the bus will compare their own hardwired address with the slave address being transmitted, after detecting a START condition. After this comparison, the TDA7512F will generate an "acknowledge" on the SDA line and will do either a read or a write operation according to the state of R/W bit.

Write operation

Following a START condition the master sends a slave address word with the R/W bit set to "0". The device will generate an "acknowledge" after this first transmission and will wait for a second word (the word address field). This 8-bit address field provides an access to any of the 32 internal addresses.

Upon receipt of the word address the TDA7512F slave device will respond with an "acknowledge". At this time, all the following words transmitted to the TDA7512F will be considered as Data.

The internal address will be automatically incremented. After each word receipt the TDA7512F will answer with an "acknowledge".

Read operation

If the master sends a slave address word with the R/W bit set to "1", the TDA7512F will transit one 8-bit data word. This data word includes the following informations:

bit0 (ISS filter, 1 = ON, 0 = OFF)

bit1 (ISS filter bandwidth, 1 = 80KHz, 0 = 120KHz)

bit2 (MPOUT, 1 = multipath present, 0 = no multipath)

bit3 (1 = PLL is locked in , 0 = PLL is locked out).

bit4 (fieldstrength indicator, 1 = lower as softmute threshold, 0 = higher as softmute threshold)

bit5 (adjacent channel indicator, 1 = adjacent channel present, 0 = no adjacent channel)

bit6 (deviation indicator, 1 = strong overdeviation present, 0 = no strong overdeviation)

bit7 (deviation indicator, 1 = overdeviation present, 0 = no overdeviation)

5.2 RDS decoder

5.2.1 Overview

The new RDS/RBDS processor contains all RDS/RBDS relevant functions on a single chip. It recovers the inaudible RDS/RBDS information which are transmitted on most FM radio broadcasting stations.

The oscillator frequency is 10.25MHz and is derived from the tuner. The fractional PLL must be initialized through I²C/SPI interface to generate the internal 8.55 MHz or 8.664 MHz reference clock (toll).

Due to an integrated 3rd order sigma delta converter, which samples the MPX signal, all further processing is done in the digital. After filtering the highly over sampled output of the A/D converter, the RDS/RBDS demodulator extracts the RDS data clock, RDS data signal and the quality information. A next RDS/RBDS decoder will synchronize the bit wise RDS stream to a group and block wise information. This processing includes an error detection and error correction algorithm. In addition, an automatic flywheel control avoids overheads in the data exchange between the RDS/RBDS processor and the host.

The device operates in accordance with the CENELEC Radio Data System (RDS) specification EN50067.

5.2.2 Fractional PLL

Figure 4. Fractional PLL

The fractional PLL (Figure 4) is used to generate from the XTI input clock one of the two possible system clocks (fsys) 8.55 MHz or 8.664 MHz. For this a setting for the input diver

factor (IDF), output divider factor (ODF), multiplication factor (MF) and fractional factor (FRA) must be found (max. f_{sys} tolerance $\pm 0.7\text{KHz}$). For fractional mode an additional dither can be enabled (DITEN) to eliminate tones in the PLL output clock. The fractional mode can be disabled (FRAEN) if not needed.

The system clock (f_{sys}) is equal to the XTI input clock after reset. After the PLL is locked, the system clock will switch automatically to the PLL output clock. Then the SPI/I²C can be used at the maximum speed of 400kbits/s.

The initialization of the PLL must be done only once after hardware reset. After PLL locking the RDS functionality can be used regardless of the PLL.

It is possible to disabled all clock for power down mode, which can be external hardware reset .

5.2.3 Sigma delta converter

The sigma delta modulator is a 3rd order (second order-first order cascade) structure. Therefore a multi bit output (2 bit streams) represents the analog input signal. A next digital noise canceller will take the 2 bit streams and calculates a combined stream which is then fed to the decimation filter. The modulator works at a sampling frequency of $f_{sys}/2$. The over sampling factor in relation to the band of interest ($57\text{KHz} \pm 2.4\text{KHz}$) is 38.

5.2.4 Demodulator

The demodulator includes:

- RDS quality indicator with selectable sensitivity
- Selectable time constant of 57KHz PLL
- Selectable time constant of bit PLL
- Time constant selection done automatically or by software

The demodulator is fed by the 57KHz bandpass filter and interpolated multiplex signal. The input signal passes a digital filter extracting the sinus and cosinus components, to be used for further processing.

The sign of both channels are used as input for the ARI indicator and for the 57KHz PLL.

A fast ARI indicator determines the presence of an ARI carrier. If an ARI carrier is present, the 57KHz PLL is operating as a normal PLL, else it is operating as a Costas loop.

One part of the PLL is compensating the integral offset (frequency deviation between oscillator and input signal).

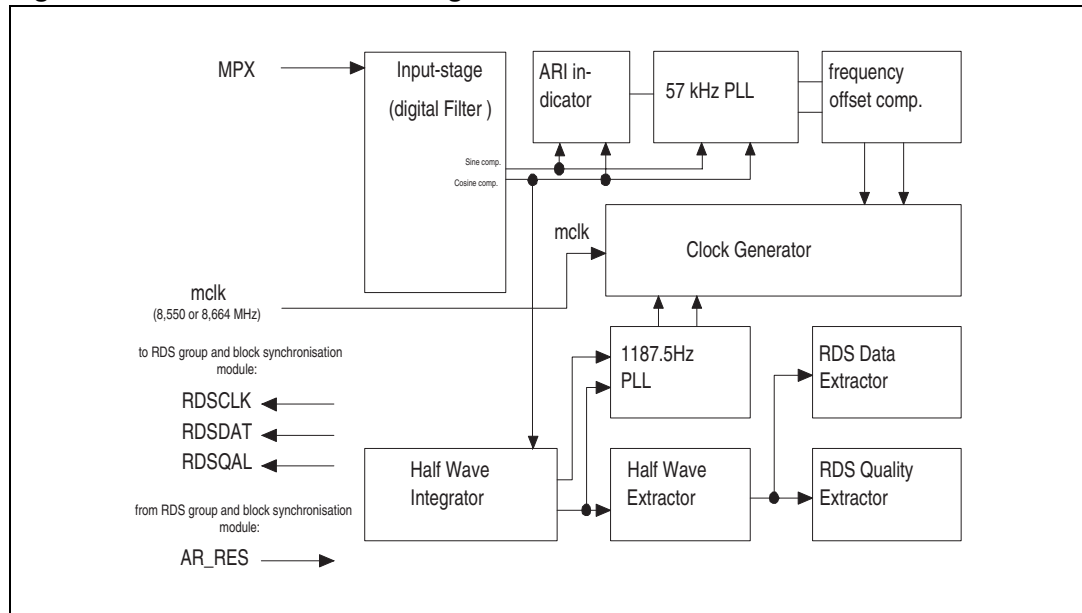

One channel of the filter is fed into the half wave integrator. Two half waves are created, with a phase deviation of 90 degrees. One wave represents the RDS component, whereas the other wave represents the ARI component.

The sign of both waves are used as reference for the bit PLL (1187.5 Hz).

The RDS wave is then fed into the half wave extractor. This leads into an RDS signal, which after integration and differential decoding represents the RDS data.

In a similar way a quality bit can be calculated. This is useful to optimize error correction.

Figure 5. Demodulator block diagram

The module needs a fixed clock of 8.55MHz. Optionally an 8.664MHz clock may be used by setting the corresponding bit in `rds_bd_ctrl` register (refer to [Table 42](#)).

In order to optimize the error correction in the group and block synchronization module, the sensitivity level of the quality bit can be adjusted in four steps with “qsens” bits `rds_bd_ctrl[5:4]`. Only bits marked as bad by the quality bit are allowed to be corrected in the group and block synchronization module. If an error correction is done on a good marked RDS bit, the “data_ok” bit `rds_corr[1]` will not be set .

The RDS bit demodulator can be controlled by the bits 1-6 of `rds_bd_ctrl` register for example to select 57KHz PLL and 1187.5Hz PLL time constant. This is useful in order to achieve a fast synchronization after a program resp. frequency change (fast time constant) and to get a maximum of noise immunity after synchronization (slow time constant).

The user may choose between 2 possibilities via bit `rds_bd_ctrl[1]`:

- Hardware selected time constant - In this case both pll time constants are reset to the fastest one, with a reset from the group and block synchronization module, or if the software decides to resynchronize by setting “ar_res” `rds_int[5]` . Then both PLLs increase automatically to the slowest time constant. This is done in four steps within a total time of 215.6 ms (256 RDS clocks).
- Software selected time constant - In this case the time constant of both PLL can be selected individually by software (`rds_bd_ctrl[4:2]`). Four time constants (5 ms, 15 ms, 35 ms, 76 ms) can be set independently for 1187.5 Hz PLL and two time constants (2 ms, 10 ms) for the 57 KHz PLL.

The sensitivity of the quality bit can be adjusted to four levels with the “qsens1” and “qsens0” `rds_bd_ctrl[6:5]` bits. “qsens1 = 0” and “qsens0 = 0” means minimum sensitivity, “qsens1 = 1” and “qsens0 = 1” maximum sensitivity.

5.2.5 Group and block synchronization module

The group and block synchronization module has the following features:

- Hardware group and block synchronization
- Hardware error detection
- Hardware error correction, using quality bit information to indicate bad corrections
- Hardware synchronization flywheel
- TA, TAEON information extraction
- Reset by software “ar_res”, which resets also RAM buffer addresses and RDS demodulator

Figure 6. Group and block synchronization diagram

This module is used to acquire group and block synchronization of the received RDS data stream, which is provided in a modified shortened cyclic code. For theory and implementation of modified shortened cyclic code and error correction, please refer to CENELEC Radio Data System (RDS) specification EN50067.

Group and block synchronization module can detect and correct five bit error burst in the data stream. If an error correction is done on a good quality marked RDS bit, the “data_ok” bit rds_corr[1] won’t be set (refer to page 49). Before error correction, the five MSBs of the syndrome register are stored in the “cp” bits rds_corr[7:3].

If the five LSBs of the syndrome register are zero, the “cp” pattern is used for error correction. After that operation the syndrome must become zero for valid RDS data. The type of error can be measured with the five “cp” bits in order to classify the reliability of the correction. Each bit set within “cp” means that one bit was corrected.

The two RDS data bytes rds_bd_h[7:0] and rds_bd_l[7:0] are available at the I²C/SPI interface together with status bits rds_corr[7:0] and rds_qu[7:0] giving reliability information of the data (refer to Figure 5). rds_int[7:0] bits are used for interrupt and group and block

synchronization control. A software reset “ar_res” rds_int[5] can be used to force resynchronization.

An endless 2 bit block counter (A, B, C or C', D, A, B...) increments one step if a new RDS block was received. During synchronization the block counter is set to the first identified valid RDS block. Then every next RDS block must be of that type which is indicated by the block counter “blk” rds_qu[3:2]. If this is not true, then the syndrome becomes not zero (indicated by “synz” bit rds_qu[0]) and the “data_ok” bit rds_corr[1] is not set. In case of USA BRDS, four consecutive E blocks can be received which are indicated by the “e” bit rds_qu[1].

The quality bit counter rds_qu[7:4] counts the bad quality marked RDS bits within a RDS block.

The group and block synchronization module extracts also TA, TAEON information and detects blocks types A, B, D (refer to [Table 37](#)) which can be used as interrupt sources.

The TA interrupt is performed in two cases: If within block B the group 0A or 0B is indicated and the TA bit is set or if within block B group 15B is indicated and the TA bit is set. The TAEON interrupt is performed, if within block B group 14B is indicated and the TA bit is set.

The interrupts can be recognized on the interrupt flag “int” rds_int[0] (refer to [Table 37](#)). The external open drain pin INTN (15) is the inverted version of the “int” flag.

5.2.6 Flywheel mechanism

Figure 7. Example for flywheel mechanism

Within group and block synchronization control block a 6 bit (64 states) flywheel counter is implemented to control RDS synchronization. After reset or a forced resynchronization by setting “ar_res” bit rds_int[5], this counter increments from zero to one, if a valid RDS block was detected. Valid means the syndrome has to be zero (“synz” = 1 rds_qu[0]) without any

error corrections done on good quality marked RDS bits. Then the RDS module is synchronized. This is indicated by “synch” bit `rds_int[4]` which is set if the flywheel counter is greater than zero. Every valid consecutive RDS block (A, B, C or C', D, A, B...) increments the flywheel counter by two.

If the next consecutive RDS block has its syndrome not zero, or corrections are done on good quality marked RDS bits, then the flywheel counter decrements by one. If the flywheel counter becomes zero, then a new RDS block synchronization will be performed. If blocks of type E are detected (indicated by “e” bit `rds_qu[1]`), then the flywheel counter will be not modified, because in case of European RDS, block E is an error but not in case of USA BRDS. This means E blocks are treated as neutral in this RDS/BRDS implementation.

The “data_ok” bit `rds_corr[1]` is set only, if the flywheel counter is greater than two, the syndrome of the detected RDS block is zero and if no error corrections are done on good quality marked RDS bits.

Figure 7 shows an example for the flywheel mechanism.

The first diagram shows the relative signal quality of 26 received RDS bits. 100% means that the last received 26 RDS bits are all marked as good by the demodulator and 0% that all are marked as bad.

The second diagram gives information about the flywheel counter status. The counter value could be between 0 and 63.

The next two charts showing the bits “synch” `rds_int[4]` and “data_ok” `rds_corr[1]`

The last graph indicates every generated buffer not empty (bne) interrupt. After each interrupt the RDS data will be read out from the RAM buffer (within 22 ms), before next RDS block is written into. This is done to reset the interrupt flag “int” `rds_int[0]` each time. Further the “syncw” bit `rds_bd_ctrl[0]` is set to one, to store only synchronized RDS blocks .

The following case is considered now: First the receiving condition is good (section 1), then it is going to be worse (section 2) because of entering a tunnel, after leaving it is going to be better again (section 3).

Section 1:

After power up or resynchronization (“ar_res”, `rds_int[5]`), the first recognized RDS block is stored in the RAM buffer and generates an “bne” interrupt. At the same time “synch” bit `rds_int[4]` is set to one. With the next stored RDS block the “data_ok” bit `rds_corr[1]` is set, because the flywheel counter becomes greater than two.

With every next RDS block the flywheel counter increments by two, until the upper margin of 63 is reached.

Section 2:

Because of entering a tunnel, the demodulator increases bad marked RDS bits until all are marked as bad. The flywheel counter decrements by one after each new RDS block because of error corrections done on good marked RDS bits or because the syndrome of the expected block was not zero after error correction. The “data_ok” bit `rds_corr[1]` is set to zero whenever the flywheel counter decrements. Note that the synchronization flag “synch” `rds_int[4]` is set and the interrupt is performed after every expected RDS block, until the flywheel counter is zero.

Then the RDS is desynchronized. Now spurious interrupts could occur because of random RDS blocks detected during resynchronization process. If the time of

receiving bad signal is shorter than the decreasing time of the flywheel counter, then the RDS will keep its synchronization and stores RDS data every 22ms.

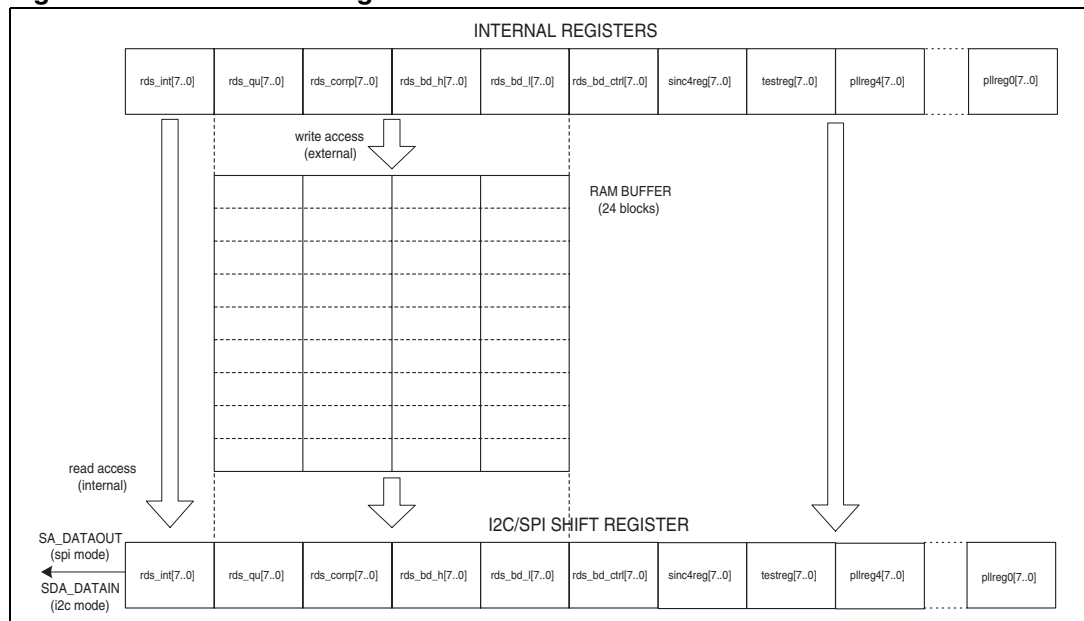

Section 3:

After leaving the tunnel, the signal is getting better and the RDS will be synchronized again as described in section 1.

5.2.7 RAM buffer

The RAM buffer can store up to 24 RDS blocks (rds_bd_h[7:0] and rds_bd_l[7:0]) with their related information (rds_qu[7:0] and rds_corr[7:0]) (Figure 7):

Figure 8. RAM buffer usage

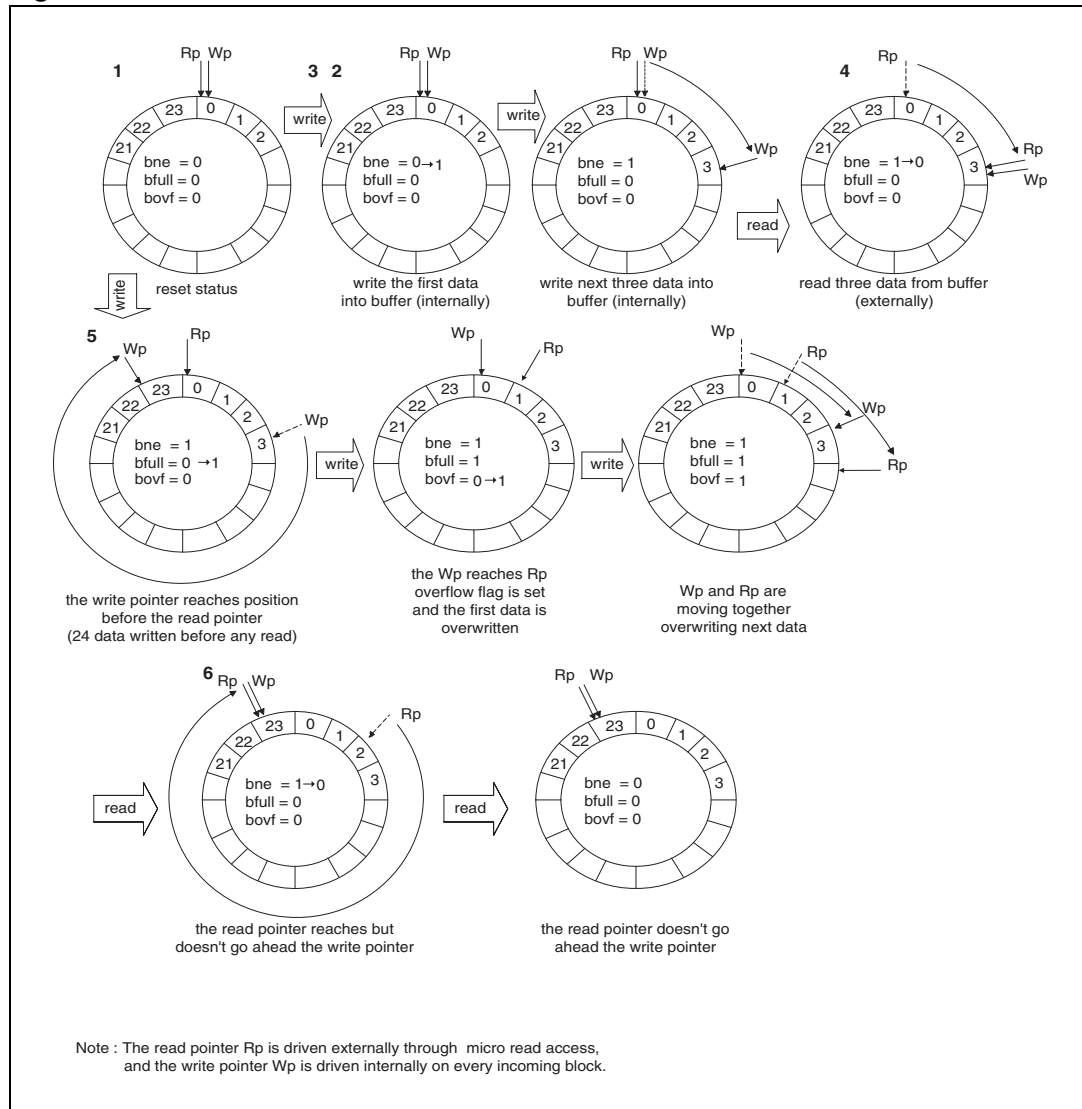

After power up, or after resynchronization by setting “ar_res” rds_int[5] to one, incoming RDS blocks are stored in the RAM buffer when synchronization has been established (Figure 8). But if the bit “syncw” rds_bd_ctrl[0] (refer to page 50) is cleared, every received RDS block is stored, also without synchronization. This means if the RDS is not synchronized, every received consecutive 26 RDS data bits are treated as a RDS block.

Figure 9. RAM buffer update depends on “syncw” bit rds_bd_ctrl[0]

The RAM buffer is used as a circular FIFO (*Figure 9*). If more than 24 blocks are written, the oldest data will be overwritten. One level of the buffer consists of 4 bytes (2 information bytes, 2 RDS data bytes). If less than 4 bytes of the RAM buffer are read out from the master via the SPI or I²C interface, the buffer address will not be incremented.

Figure 10. RAM buffer states

The different states of the buffer are indicated with the help of following flags:

- “bne”, buffer not empty. It is set as soon as one RDS block is written in the buffer, and reset when reading rds_int register. This flag is a bit of rds_int register, it is also an interrupt source .
- “bfull”, buffer full. It is set when 24 RDS blocks have been written, that is to say that there is about 20 ms to read out the buffer content before an overflow occurs. This flag is an interrupt source.
- “bovf”, buffer overflow. It is set if more than 24 RDS blocks are written. This flag is a bit of register rds_corr (refer to *Table 39*) and is cleared only by reading the whole buffer (24 blocks).

An address reset of the RAM buffer can be performed by writing a 1 to “ar_res” bit in rds_int register, it also forces a resynchronization.

Figure 10 describes the different states of the buffer with corresponding flags values:

1. This is the reset state, read (Rp) and write pointer (Wp) pointing at the same location 0. The buffer is empty.
2. After the first buffer write operation, Wp points to the last written data (0, it is not incremented) and the flag “bne” (buffer not empty) is set.
3. After next buffer write operation, Wp points to the last written data (3, incremented address).
4. After buffer read operation, Rp points to incremented address (data to be read on the next read cycle), following the Wp. As soon as Rp reaches the Wp (of value 3), it is not incremented to 4 and flag “bne” is reset. Rp never goes ahead the Wp.
5. If the buffer is full (i.e. 24 blocks have been written before any read), flag “bfull” is set. If no read operation is performed, on next write operation “bovf” (buffer overflow) is set, and each subsequent write operation will overwrite the oldest data of the RAM buffer. Rp is moved in front of the Wp.
6. If the whole content of the buffer has already been read, subsequent read operation will always read the last written location - Rp never goes ahead the Wp.

6 Software specifications

6.1 Tuner software specification

The interface protocol comprises:

- start condition (S)
- chip address byte
- subaddress byte
- sequence of data (N bytes + Acknowledge)
- stop condition (P)

Figure 11. Tuner software specification

S = Start

P = Stop

ACK = Acknowledge

D = Device Address

X = R/W bit

I = Pagemode

A = Subaddress

6.3 RDS decoder software specification

6.3.1 Programming through serial bus interface

The serial bus interface is used to access the different registers of the chip. It is able to handle both I²C and

SPI transfer protocols, the selection between the two modes is done thanks to the pin CSN:

- if the pin CSN is high, the interface operates as an I²C bus.
- if the pin CSN is asserted low, the interface operates as a SPI bus.

In both modes, the device is a slave, i.e the clock pin SCL_CLK is only an input for the chip.

Depending on the transfer mode, external pins have alternate functions as following:

Table 35. External pins alternate functions

| pin | function in SPI mode (CSN=0) | function in I ² C mode (CSN=1) |
|------------|------------------------------|---|
| SCL_CLK | CLK (serial clock) | SCL (serial clock) |
| SDA_DATAIN | DATAIN (data input) | SDA (data line) |
| SA_DATAOUT | DATAOUT (data output) | SA (slave address) |

13 registers are available with read or read/write access:

Table 36. Registers description

| register | access rights | function |
|------------------|---------------|--|
| rds_int[7:0] | read/write | interrupt source setting, synch., bne information |
| rds_qu[7:0] | read | quality counter, actual block name |
| rds_corr[7:0] | read | error correction status, buffer ovf information |
| rds_bd_h[7:0] | read | high byte of current RDS block |
| rds_bd_l[7:0] | read | low byte of current RDS block |
| rds_bd_ctrl[7:0] | read/write | frequency, quality sensitivity, demodulator pll settings |
| sinc4reg[7:0] | read/write | sinc4 filter settings (for internal use only) |
| testreg[7:0] | read/write | test modes (for internal use only) |
| pllreg4[7:0] | read/write | PLL control register 4 |
| pllreg3[7:0] | read/write | PLL control register 3 |
| pllreg2[7:0] | read/write | PLL control register 2 |
| pllreg1[7:0] | read/write | PLL control register 1 |
| pllreg0[7:0] | read/write | PLL control register 0 |

The meaning of each bit is described below:

Table 37. rds_int register

| rds_int | bit 7 | bit 6 | bit 5 | bit 4 | bit 3 | bit 2 | bit 1 | bit 0 |
|-------------|-------|-------|--------|-------|--------|--------|--------|-------|
| reset value | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| bit name | write | bne | ar_res | synch | itsrc2 | itsrc1 | itsrc0 | int |
| access | r/w | r | r/w | r | r/w | r/w | r/w | r |

(1)

| interrupt source | itsrc2 | itsrc1 | itsrc0 |
|------------------|--------|--------|--------|
| no interrupt | 0 | 0 | 0 |
| buffer not empty | 0 | 0 | 1 |
| buffer full | 0 | 1 | 0 |
| block A | 0 | 1 | 1 |
| block B | 1 | 0 | 0 |
| block D | 1 | 0 | 1 |
| TA | 1 | 1 | 0 |
| TA EON | 1 | 1 | 1 |

Interrupt bit. It is set to one on every programmed interrupt. It is reset by reading rds_int register. The inverted version is also externally available on RDSINT pin.

itsrc[2:0] selects interrupt source (1).
Block A, B, D and TA, TA EON interrupts only if "synch" =1.

Synchronization information (refer to pages 28-29).
1: The module is already synchronized.
0: The module is synchronizing.

It is used to force a resynchronization. If it is set to one, the RDS modules are forced to resynchronization state and the RAM buffer address is reset.
This bit is reset automatically. It is read always as zero.

Buffer not empty.
1: At least one block is present in the RAM buffer.
0: The RAM buffer is empty.

rds_int, rds_bd_ctrl and pllreg4-0 write order.
This bit is only used in SPI mode and is read always as zero.
1: Update of rds_int, rds_bd_ctrl and pllreg4-0 with data shifted in.
0: No update of rds_int, rds_bd_ctrl and pllreg4-0.

(1) If the interrupt source is changed from block A, B, D, TA, TA EON to another one "no interrupt" must be set before to clear the previous interrupt acknowledge.

Table 38. rds_qu register

| rds_qu | bit 7 | bit 6 | bit 5 | bit 4 | bit 3 | bit 2 | bit 1 | bit 0 |
|-------------|-------|-------|-------|-------|-------|-------|-------|-------|
| reset value | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| bit name | qu3 | qu2 | qu1 | qu0 | blk1 | blk0 | e | synz |
| access | r | r | r | r | r | r | r | r |

(2)

| block name | blk1 | blk0 |
|------------|------|------|
| block A | 0 | 0 |
| block B | 0 | 1 |
| block C,C' | 1 | 0 |
| block D | 1 | 1 |

It indicates if error correction was successful.
1: The syndrome was zero after error correction.
0: The syndrome did not become zero and therefore the error correction was not successful.

1: Block E is detected. This indicates a paging block which is defined in the RBDS specification used in the United States of America.
0: An ordinary RDS block A, B, C, C' or D is detected, or no valid syndrome was found.

Bit 0 of block counter (2).
bit 1 of block counter (2).
bit 0 of quality counter (3).
bit 1 of quality counter (3).
bit 2 of quality counter (3).
bit 3 of quality counter (3).

(2) If "synzw" =1 of rds_bd_ctrl register, the block counter indicates the expected RDS block.

(3) qu[3...0] counts the number of bits (max.16) which are marked as bad by the demodulator within each RDS block. It could be used as a quality information, indicating the maximum number of bits which are allowed to be corrected.

Table 39. rds_corrp register

| rds_corrp | bit 7 | bit 6 | bit 5 | bit 4 | bit 3 | bit 2 | bit 1 | bit 0 |
|-------------|-------|-------|-------|-------|-------|---------|--------|-------|
| reset value | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| bit name | cp9 | cp8 | cp7 | cp6 | cp5 | correct | dat_ok | bovf |
| access | r | r | r | r | r | r | r | r |

| |
|---|
| <p>Buffer overflow 1: More than 24 blocks have been written into the buffer. 0: No buffer data has been overwritten.</p> |
| <p>Information if the current RDS data could be used. 1: A correct syndrome was detected and no error correction was done on a good quality marked RDS bit and the flywheel counter is greater than 2 (RDS data is OK). 0: The syndrome was wrong, or an error correction was done on a good quality marked RDS bit, or the flywheel counter is lower than 3 (RDS data is not OK).</p> |
| <p>It is an information about error correction. 1: An error correction was done. 0: The actual RDS block is detected as error free.</p> |
| bit 5 of the syndrome register(4). |
| bit 6 of the syndrome register(4). |
| bit 7 of the syndrome register(4). |
| bit 8 of the syndrome register(4). |
| bit 9 of the syndrome register(4). |

(4) (Refer to CENELEC Radio Data System specification EN50067, ANNEX B). When bits 0...4 of the syndrome register are zero, a possible error burst is detected. With help of the correction pattern (bits 5...9 of the syndrome register), the type of error can be measured, in order to classify the reliability of the correction.

Write into buffer if synchronized (refer to page 10-12) (8)
 1: Write into buffer only if synchronized (reset value).
 0: Write into buffer any incoming RDS block.

Select PLL time constants by software or hardware (8)
 1: Software. Time constants are selected by pllb[1:0] respectively pllf.
 0: Hardware (reset value). Time constants automatically increase after reset or resynchronization.

Set the 57 kHz pll time constant (5) (8).

Bit 0 of 1187.5 Hz pll time constant (6) (8).

Bit 1 of 1187.5 Hz pll time constant (6) (8).

Bit 0 of quality sensitivity (7) (8).

Bit 1 of quality sensitivity (7) (8).

Select internal master clock frequency (fsys):
 1: 8.664 MHz.
 0: 8.55 MHz (reset value).

(5)

| pllf | lock time needed for 90 deg deviation |
|------|---------------------------------------|
| 0 | 2 ms |
| 1 | 10 ms |

(6)

| pllb1 | pllb0 | lock time needed for 90 deg deviation |
|-------|-------|---------------------------------------|
| 0 | 0 | 5 ms (reset status) |
| 0 | 1 | 15 ms |
| 1 | 0 | 35 ms |
| 1 | 1 | 76 ms |

(7) Select sensitivity of quality bit.
 00: minimum (reset value)
 11: maximum

(8) Bit 5 "ar_res" of rds_int register will clear the bits 0-6 of the rds_bd_ctrl register.

Table 43. sinc4reg register

| sinc4reg | bit 7 | bit 6 | bit 5 | bit 4 | bit 3 | bit 2 | bit 1 | bit 0 |
|-------------|-------|-------|-------|-------|-------|-------|-------|-------|

| bit 2 of fractional factor (10). |
| bit 3 of fractional factor (10). |
| bit 4 of fractional factor (10). |
| bit 5 of fractional factor (10). |
| bit 6 of fractional factor (10). |
| bit 7 of fractional factor (10). |

(12) The registers pllreg3, pllreg2 and pllreg1 must be written at once to be updated, i.e. if the I2C/SPI stops after pllreg2, then these registers are not updated.

Note: *sinc4reg and testreg registers are dedicated for testing and are not described in this specification.*

Reset values of rds_qu, rds_corr_p, rds_bd_h and rds_bd_l registers are not visible for the programmer, because he can see only the copy of this registers in the RAM buffer after a new RDS block was received.

The pllreg4-0 registers must be initialized first, before the RDS functionality can be used. If the “PLLEN” bit of pllreg4 is set from zero to one, then the PLL will be initialized after I²C/SPI transfer with the actual values of pllreg4-0. After the lock time the PLL switches automatically over to the PLL output clock. The next I²C/SPI transfer is only allowed after the lock time (500µs) and additional 25 XT1 input clock cycles. If the “PLLEN” bit is set from one to zero, the PLL will be stopped and the system clock is switched back to the XT1 input clock (after the I²C/SPI transfer). The next I²C/SPI transfer is then only allowed after 25 XT1 input clock cycles. This is to avoid any I²C/SPI communication during clock switching.

The registers pllreg3-1 can be only changed at once. If there are less than all three pllreg3-1 registers written during a I²C/SPI transfer, then they will be not updated.

If the XT1 input frequency is 10.25MHz, then only register pllreg4 must be programmed, because the pllreg3-0 register reset values can be used without any modification.

6.3.2 I²C transfer mode

This interface consists of three lines: a serial data line (SDA), a bit clock (SCL), and a slave address select (SA).

The interface is capable of operating up to 400kbits/s. If during the setup the system clock fsys is smaller than 8.55MHz, then the max. I²C speed decreases linear (e.i. if fsys = 4.275MHz then the maximum I²C speed is 200 kbits/s for setup).

Data transfers follow the format shown in After the START condition (S), a slave address is sent. The address is 7 bits long followed by an eighth bit which is a data direction bit (R/_W).

A zero indicates a transmission (WRITE), a one indicates a request for data (READ).

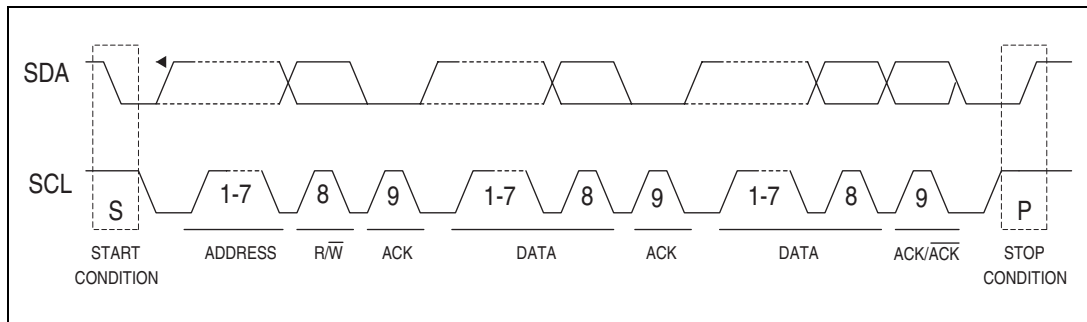

The slave address of the chip is set to 001000S, where S is the least significant bit of the slave address set externally via the pin SA_DATAOUT. This allows to choose between two addresses in case of conflict with another device of the radio set.

Each byte has to be followed by an acknowledge bit (SDA low).

Data is transferred with the most significant (MSB) bit first.

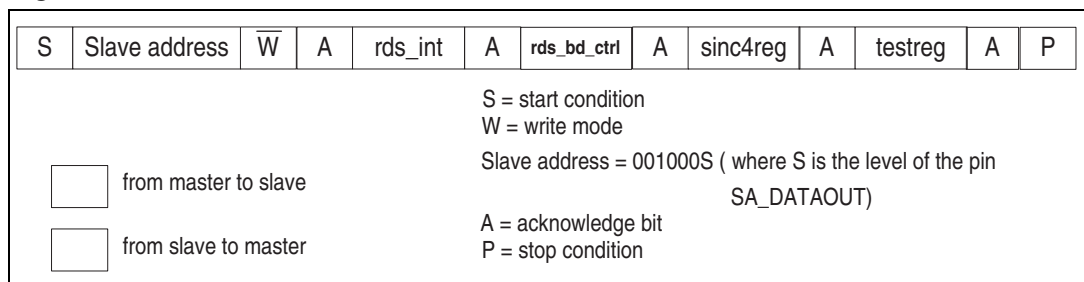

A data transfer is always terminated by a stop condition (P) generated by the master.

Figure 12. I²C data transfer

Write transfer

Figure 13. I²C write transfer

9 registers are available with write access (please refer to the relevant sections for the meaning of each bit).

To write registers, the external master must initiate the write transfer as described above, then send the data to be written, and terminate the transfer by generating a stop condition. The transfer can be terminated after having written one, two, three, four (Figure 13), or five bytes.

The registers are written in the following order:

rds_int[7:0], rds_bd_ctrl[7:0], sinc4reg[7:0], testreg[7:0], pllreg4[7:0], pllreg3[7:0], pllreg2[7:0], pllreg1[7:0], pllreg0[7:0].

sinc4reg[7:0] and testreg[7:0] are dedicated for test and have to keep zero filled for application.

Figure 14. I²C write operation example: write of rds_int and rds_bd_ctrl registers

Read transfer

Figure 15. I²C read transfer

13 bytes can be read at a time (please refer to the to the relevant sections for the meaning of each bit).

The master has the possibility to read less than 13 registers by not sending the acknowledge bit and then generating a stop condition after having read the needed amount of registers.

There are two typical read access:

- read only the first register rds_int to check the interrupt bit.
- read the first five registers rds_int, rds_qu, rds_corr, rds_bd_h and rds_bd_l to get the RDS data.

The registers are read in the following order:

rds_int[7:0], rds_qu[7:0], rds_corr[7:0], rds_bd_h[7:0], rds_bd_l[7:0], rds_bd_ctrl[7:0], sinc4reg[7:0], testreg[7:0], pllreg4[7:0], pllreg3[7:0], pllreg2[7:0], pllreg1[7:0], pllreg0[7:0].

Only the “bne” flag can be used for polling mode. There are two different ways to use this mode, while the first one causes less bus traffic than the second:

1. Read only the first register rds_int to check the “bne” bit.
If “bne” bit is not set, the stop condition can be set, as shown in (Figure 17).

If “bne” bit is set, the transfer must be continued by the I²C master, until at least the four register rds_qu, rds_corr, rds_bd_h and rds_bd_l are read out, then the I²C master is allowed to set the stop condition (Figure 16). Then the whole Buffer must be read out, by reading each time at least the five registers rds_int, rds_qu, rds_corr, rds_bd_h and rds_bd_l without interruption. This must be done until the “bne” bit is set to zero (last RDS block).

2. If the I²C master is not able to handle the above protocol, it must read always at least the first five registers rds_int, rds_qu, rds_corr, rds_bd_h, rds_bd_l out independent if “bne” is set or not (Figure 16). If the “bne” flag is set the whole RAM buffer must be read out, by reading each time at least the five registers rds_int, rds_qu, rds_corr, rds_bd_h and rds_bd_l without interruption. This must be done until the “bne” bit is set to zero (last RDS block).

Note: In polling mode the interrupt flag “int” is just a indication that the wanted information is stored within the RAM Buffer.

Note: In polling mode it is possible that the last RDS data (rds_qu, rds_corr, rds_bd_h and rds_bd_l), which was read out as the “bne” flag was set to zero, is identical to the RDS data before. This must be checked by the external micro controller by comparing the last received 2 RDS blocks. If they are identical, one of them can be skipped. (This is the case if just one RDS block is stored in the RAM buffer).

Figure 16. I²C read access example 1: read of 5 bytes

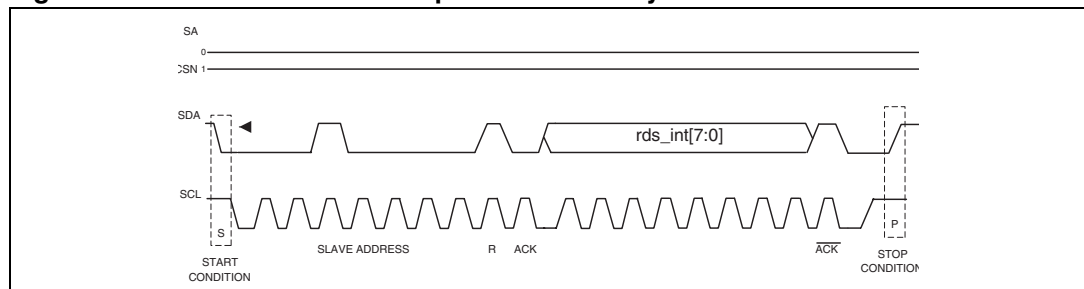

Figure 17. I²C read access example 2: read of 1 byte

6.3.3 SPI mode

Figure 18. SPI data transfer

This interface consists of four lines (*Figure 18*). A serial data input (DATAIN), a serial data output (DATAOUT), a chip select input (CSN) and a bit clock input (CLK).

The interface is capable of operating up to 1 MHz. If during the setup the system clock f_{sys} is smaller than 8.55 MHz, then the max. SPI speed decreases linear (e.i. if $f_{sys} = 4.275$ MHz then the maximum SPI speed is 500KHz for setup).

CSN starts and stops the data transfer. After starting data transfer, one bit is shifted out (DATAOUT) with the active bit clock edge (CLK) and at the same time one bit in (DATAIN). When CSN stops the data transfer, the pllreg0[7:0], pllreg1[7:0], pllreg2[7:0], pllreg3[7:0], pllreg4[7:0], rdstest[7:0], sinc4reg[7:0], rds_bd_ctrl[7:0], rds_int[7:0] registers can be updated with the last bytes which have been shifted in.

The last byte shifted in on DATAIN must be always rds_int[7:0] and the last but one is rds_bd_ctrl[7:0], and so on, as listed above. In other words, the master has take into account the number of bytes to transfer before starting, to be sure that the last byte shifted in at DATAIN is rds_int[7:0].

If the pllreg0[7:0], pllreg1[7:0], pllreg2[7:0], pllreg3[7:0], pllreg4[7:0], rdstest[7:0], sinc4reg[7:0], rds_bd_ctrl[7:0], rds_int[7:0] registers will be updated depends on the MSB of rds_int. If $rds_int[7] = 1$ all registers listed above are updated (refer to page 48). The registers pllreg3-1 are only updated if they are shifted completely into the SPI.

sinc4reg[7:0] and testreg[7:0] are dedicated for test **and have to be kept zero filled** in the application, independent if rds_int[7] bit is set or not.

Only the “bne” flag can be used for polling mode. There are two different ways to use **polling mode**, while the first one causes less bus traffic than the second:

1. Read only the first register rds_int to check the “bne” bit.
If “bne” bit is not set, the CSN can be set, as shown in (*Figure 21*).
If “bne” bit is set, the transfer must be continued by the SPI master, until at least the four register rds_qu, rds_corr, rds_bd_h and rds_bd_l are read out, then the SPI master is allowed to stop the transfer by pulling CSN up. Then the whole Buffer must be read out, by reading each time at least the five registers rds_int, rds_qu, rds_corr,

rds_bd_h and rds_bd_l without interruption. This must be done until the “bne” bit is set to zero (last RDS block).

2. If the SPI master is not able to handle the above protocol, it must read always at least the first five registers rds_int, rds_qu, rds_corr, rds_bd_h, rds_bd_l out independent if “bne” is set or not. If the “bne” flag is set the whole RAM Buffer must be read out, by reading each time at least the five registers rds_int, rds_qu, rds_corr, rds_bd_h and rds_bd_l without interruption. This must be done until the “bne” bit is set to zero (last RDS block).

Note: In polling mode the interrupt flag “int” is just a indication that the wanted information is stored within the RAM buffer.

Note: In polling mode it is possible that the last RDS data (rds_qu, rds_corr, rds_bd_h and rds_bd_l), which was read out as the “bne” flag was set to zero, is identical to the RDS data before. This must be checked by the external micro controller by comparing the last received 2 RDS blocks. If they are identical, one of them can be skipped (This is the case if just one RDS block is stored within the RAM buffer).

Hereafter you can find typical read/write access in SPI mode:

Figure 19. Write rds_int, rds_bd_ctrl and pll_reg4 registers in SPI mode, reading RDS data and related flags

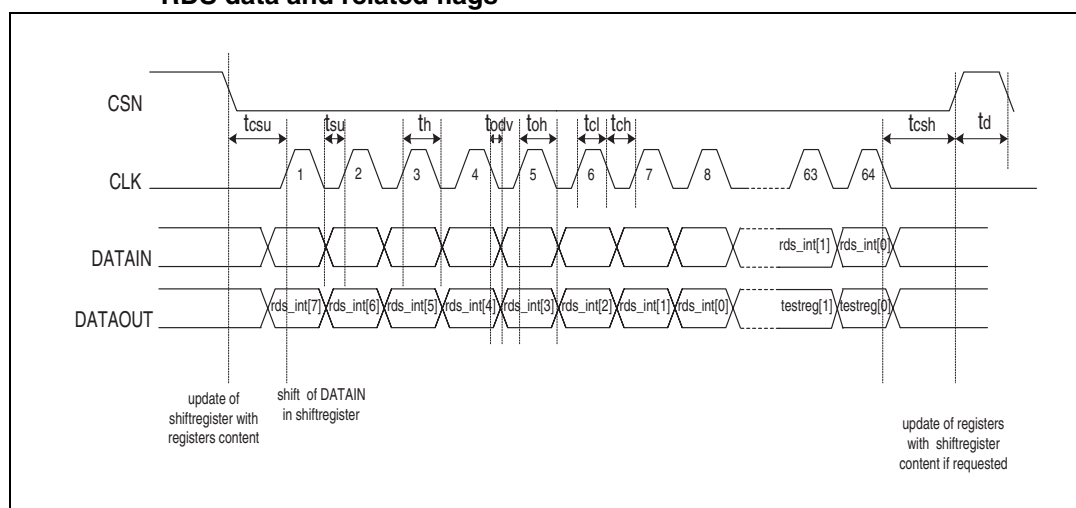

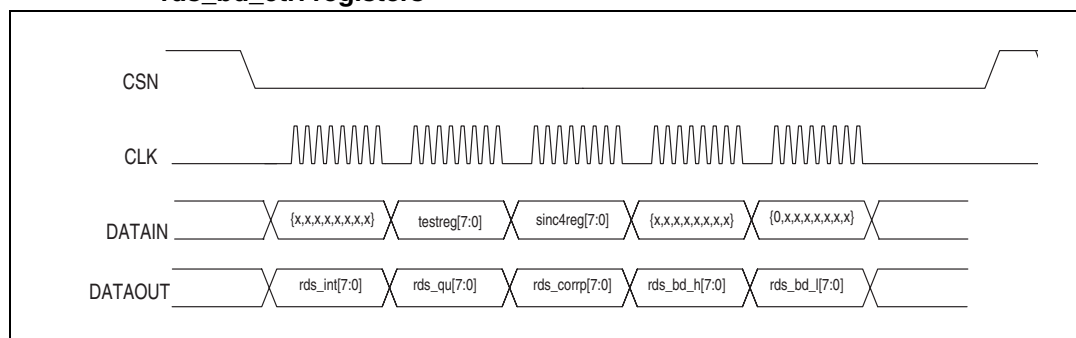

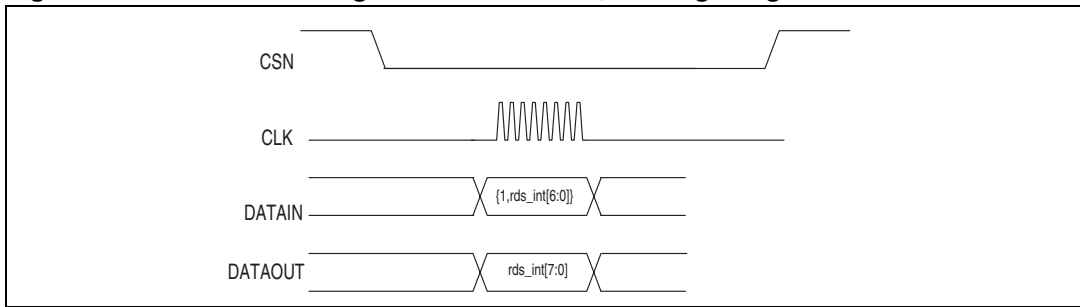

Figure 20. Read out RDS data and related flags, no update of rds_int and rds_bd_ctrl registers

Note: sinc4reg and testreg must be zero filled for application.

Figure 21. Write rds_int registers in SPI mode, reading 1 register

The content of the RDS registers is clocked out on DATAOUT pin in the following order:

rds_int[7:0], rds_qu[7:0], rds_corr[7:0], rds_bd_l[7:0], rds_bd_h[7:0], rds_ctrl[7:0], sinc4reg[7:0], testreg[7:0], pllreg4[7:0], pllreg3[7:0], pllreg2[7:0], pllreg1[7:0], pllreg0[7:0].

For the meaning of each bit please refer to the relevant sections.

Note: After 40 bit clocks the whole RDS data and flags are clocked out.

8 Application notes

8.1 Typical RDS data transfer:

1. After power up the device, the PLL must be initialized and enabled to generate the 8.55 MHz or 8.664 MHz system clock (fsys). If the XTI frequency is already 8.55 MHz or 8.664 MHz, this point can be skipped. If not, the pllreg4-0 register must be programmed via I²C/SPI. If the XTI frequency is smaller than 8.55 MHz, the reduced maximum I²C/SPI speed must be considered. After the pllreg4-0 register has been programmed, 500 us and additional 25 XTI input clock cycles must be waited until the PLL is locked and the system clock fsys is switched over to the PLL output clock. Then the next I²C/SPI transfer is allowed with its maximum speed specified for the 8.55/8.664 MHz system clock (fsys).
2. In the next I²C/SPI transfer the interrupt source will be set to “buffer not empty” (itsrc[2:0] = 001) and a resynchronization should be forced (rds_int[5] = 1), to be sure that the buffer is empty and not filled with spurious RDS data. To do this only a write access to the first register rds_int is needed.
3. Now the pin INTN must be continuously checked for an interrupt (active low). If there is an interrupt the five registers rds_int, rds_qu, rds_corr, rds_bd_h and rds_bd_l must be read out to get the RDS data. The next interrupt can not be expected before 22 ms.
4. If it is not possible to service the interrupt in time, then the RDS buffer can store up to 24 RDS blocks. If the buffer is full and the data could not be read before the next RDS block, the “buffer overflow” flag (rds_corr[0] = 1) will be set. In this case at least one RDS block is missed. The “buffer overflow” flag is only cleared, if the whole RDS buffer is read out.

If there is no pin available for checking the INTN pin, then it is possible to read out the RDS data by I²C/SPI polling. Only the “buffer not empty” flag (rds_int[6]) can be used for that. If rds_int[6] bit is set, the I²C/SPI transfer must be continued, until at least the four registers rds_qu, rds_corr, rds_bd_h and rds_bd_l are read out.

This must be done until rds_int[6] bit is set to zero (last RDS block). It is possible that the last RDS block is the same as the last but one RDS block. This is the case if just one RDS block was stored in the RAM buffer. If they are identical, one of them can be skipped.

If another interrupt source is used instead of “buffer not empty” for the INTN pin, also the polling mode must be used for reading out the whole RDS buffer, as described above.

9 Package information

In order to meet environmental requirements, ST offers these devices in ECOPACK® packages. These packages have a Lead-free second level interconnect. The category of second Level Interconnect is marked on the package and on the inner box label, in compliance with JEDEC Standard JESD97. The maximum ratings related to soldering conditions are also marked on the inner box label. ECOPACK is an ST trademark.

ECOPACK specifications are available at: www.st.com.

10 Revision history

Table 51. Document revision history

| Date | Revision | Changes |
|-------------|----------|---|
| 02-Nov-2005 | 1 | Initial release. |
| 14-Nov-2005 | 1.1 | Minor corrections. |
| 05-Dec-2005 | 1.2 | Updated datas in the Electrical specification chapter. |
| 22-Dec-2005 | 1.3 | Minimum tuner supply voltage changed to 7.7V. |
| 13-Jan-2006 | 1.4 | Updated datas in the Electrical specification chapter. |
| 02-Feb-2006 | 1.5 | Corrected Figure 11 , Table 48 & 49 . |
| 08-Mar-2006 | 1.6 | Changed Vco impedance value. |
| 04-May-2006 | 2 | First issue in st.com web site. |
| 30-May-2006 | 3 | Corrected type error in Order Codes table. |
| 30-Oct-2006 | 4 | Changed Table 40 . |

Please Read Carefully:

Information in this document is provided solely in connection with ST products. STMicroelectronics NV and its subsidiaries ("ST") reserve the right to make changes, corrections, modifications or improvements, to this document, and the products and services described herein at any time, without notice.

All ST products are sold pursuant to ST's terms and conditions of sale.

Purchasers are solely responsible for the choice, selection and use of the ST products and services described herein, and ST assumes no liability whatsoever relating to the choice, selection or use of the ST products and services described herein.

No license, express or implied, by estoppel or otherwise, to any intellectual property rights is granted under this document. If any part of this document refers to any third party products or services it shall not be deemed a license grant by ST for the use of such third party products or services, or any intellectual property contained therein or considered as a warranty covering the use in any manner whatsoever of such third party products or services or any intellectual property contained therein.

UNLESS OTHERWISE SET FORTH IN ST'S TERMS AND CONDITIONS OF SALE ST DISCLAIMS ANY EXPRESS OR IMPLIED WARRANTY WITH RESPECT TO THE USE AND/OR SALE OF ST PRODUCTS INCLUDING WITHOUT LIMITATION IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE (AND THEIR EQUIVALENTS UNDER THE LAWS OF ANY JURISDICTION), OR INFRINGEMENT OF ANY PATENT, COPYRIGHT OR OTHER INTELLECTUAL PROPERTY RIGHT.

UNLESS EXPRESSLY APPROVED IN WRITING BY AN AUTHORIZED ST REPRESENTATIVE, ST PRODUCTS ARE NOT RECOMMENDED, AUTHORIZED OR WARRANTED FOR USE IN MILITARY, AIR CRAFT, SPACE, LIFE SAVING, OR LIFE SUSTAINING APPLICATIONS, NOR IN PRODUCTS OR SYSTEMS WHERE FAILURE OR MALFUNCTION MAY RESULT IN PERSONAL INJURY, DEATH, OR SEVERE PROPERTY OR ENVIRONMENTAL DAMAGE. ST PRODUCTS WHICH ARE NOT SPECIFIED AS "AUTOMOTIVE GRADE" MAY ONLY BE USED IN AUTOMOTIVE APPLICATIONS AT USER'S OWN RISK.

Resale of ST products with provisions different from the statements and/or technical features set forth in this document shall immediately void any warranty granted by ST for the ST product or service described herein and shall not create or extend in any manner whatsoever, any liability of ST.
