

Video Gain Control/Fader

The EL4094 is a complete two-input fader. It combines two inputs according to the equation:

$$V_{OUT} = V_{INA} (0.5V + V_G) + V_{INB} (0.5V - V_G)$$

where V_{GAIN} is the difference between V_{GAIN} and $\overline{V_{GAIN}}$ pin voltages and ranges from -0.5V to +0.5V. It has a wide 60MHz bandwidth at -3dB, and is designed for excellent video distortion performance. The EL4094 is the same circuit as the EL4095, but with feedback resistors included on-chip to implement unity-gain connection. An output buffer is included in both circuits.

The gain-control input is also very fast, with a 20MHz small-signal bandwidth and 70ns recovery time from overdrive.

The EL4094 is compatible with power supplies from $\pm 5V$ to $\pm 15V$, and is available in both the 8-pin plastic DIP and SO-8.

Pinout

**EL4094
(8-PIN PDIP, SO)
TOP VIEW**

Manufactured under U.S. Patent No. 5,321,371, 5,374,898

Features

- Complete video fader
- 0.02%/0.04° differential gain/phase @100% gain
- Output amplifier included
- Calibrated linear gain control
- $\pm 5V$ to $\pm 15V$ operation
- 60MHz bandwidth
- Low thermal errors

Applications

- Video faders/wipers
- Gain control
- Video text insertion
- Level adjust
- Modulation

Ordering Information

PART NUMBER	TEMP. RANGE	PACKAGE	PKG. NO.
EL4094CN	-40°C to +85°C	8-Pin PDIP	MDP0031
EL4094CS	-40°C to +85°C	8-Pin SO	MDP0027

Absolute Maximum Ratings ($T_A = 25^\circ\text{C}$)

V_{S+}	Voltage between V_{S+} and GND	+18V	I_{OUT}	Output Current	$\pm 35\text{mA}$
V_S	Voltage between V_{S+} and V_{S-}	+33V		Internal Power Dissipation	See Curves
V_{INA}	Input Voltage	(V_{S-}) -0.3V	T_A	Operating Ambient Temp. Range	-40°C to +85°C
V_{INB}		to (V_{S+}) +0.3V	T_J	Operating Junction Temperature	150°C
V_{GAIN}	Input Voltage	$\sqrt{V_{GAIN}} \pm 5\text{V}$	T_{ST}	Storage Temperature Range	-65°C to +150°C
$\sqrt{V_{GAIN}}$	Input Voltage	V_{S-} to V_{S+}			

CAUTION: Stresses above those listed in "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress only rating and operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied.

IMPORTANT NOTE: All parameters having Min/Max specifications are guaranteed. Typical values are for information purposes only. Unless otherwise noted, all tests are at the specified temperature and are pulsed tests, therefore: $T_J = T_C = T_A$

Open-Loop DC Electrical Specifications

$V_S = \pm 5\text{V}$, $T_A = 25^\circ\text{C}$, $V_{GAIN} = +0.6\text{V}$ to measure channel A, $V_{GAIN} = -0.6\text{V}$ to measure channel B, $\sqrt{V_{GAIN}} = 0\text{V}$, unless otherwise specified. NL, $A_V = 0.25\text{V}$

PARAMETER	DESCRIPTION	LIMITS			UNITS

Applications Information

The EL4094 is a self-contained and calibrated fader subsystem. When a given channel has 100% gain the circuit behaves as a current-feedback amplifier in unity-gain connection. As such, video and transfer distortions are very low. As the gain of the input is reduced, a 2-quadrant multiplier is gradually introduced into the signal path and distortions increase with reducing gain.

The input impedance also changes with gain setting, from about 1M Ω at 100% gain down to 16k Ω at zero gain. To

maximize gain accuracy and linearity, the inputs should be driven from source impedances of 500 Ω or less.

Linearity

The EL4094 is designed to work linearly with $\pm 2V$ inputs, but lowest distortion occurs at $\pm 1V$ levels and below. Errors are closer to those of a good current-feedback amplifier above 90% gain.

Low-frequency linearity is 0.1% or better for gains 25% to 100% and inputs up to 1V. NTSC differential gain and phase errors are better than 0.3% and 0.3 $^{\circ}$ for the 25% to 100% gain range. These distortions are not strongly affected by

supply voltage nor output loading, at least down to 150Ω. For settling to 0.1%, however, it is best to not load the output heavily and to run the EL4094 on the lowest practical supply voltages, so that thermal effects are minimized.

Gain Control Inputs

The gain control inputs are differential and may be biased at any voltage as long as $\sqrt{V_{\text{GAIN}}}$ is less than 2.5V below V_+ and 3V above V_- . The differential input impedance is 5.5kΩ, and the common-mode impedance is more than 500kΩ. With zero differential voltage on the gain inputs, both signal inputs have a 50% gain factor. Nominal calibration sets the 100% gain of V_{INA} input at +0.5V of gain control voltage, and 0% at -0.5V of gain control. V_{INB} 's gain is complementary to that of V_{INA} ; +0.5V of gain control sets 0% gain at V_{INB} and -0.5V gain control sets 100% V_{INB} gain. The gain control does not have a completely abrupt transition at the 0% and 100% points. There is about 10mV of "soft" transfer at the gain endpoints. To obtain the most accurate 100% gain factor or best attenuation at 0% gain, it is necessary to overdrive the gain control input by 30mV or more. This would set the gain control voltage range as -0.565V to +0.565V, or 30mV beyond the maximum guaranteed 0% to 100% range. In fact, the gain control inputs are very complex. Here is a representation of the terminals:

FIGURE 1. REPRESENTATION OF GAIN CONTROL INPUTS V_G AND $/V_G$

For gain control inputs between $\pm 0.5V$ ($\pm 90\mu A$), the diode bridge is a low impedance and all of the current into V_G flows back out through $/V_G$. When gain control inputs exceed this amount, the bridge becomes a high impedance as some of the diodes shut off, and the V_G impedance rises sharply from the nominal 5.5KΩ to about 500KΩ. This is the condition of gain control overdrive. The actual circuit produces a much sharper overdrive characteristic than does the simple diode bridge of this representation.

The gain input has a 20MHz -3dB bandwidth and 17ns risetime for inputs to $\pm 0.45V$. When the gain control voltage exceeds the 0% or 100% values, a 70ns overdrive recovery transient will occur when it is brought back to linear range. If quicker gain overdrive response is required, the Force control inputs of the EL4095 can be used.

Output Loading

The EL4094 does not work well with heavy capacitive loads. Like all amplifier outputs, the output impedance becomes inductive over frequency resonating with a capacitive load. The effective output inductance of the EL4094 is about 350nH. More than 50pF will cause excessive frequency response peaking and transient ringing. The problem can be solved by inserting a low-value resistor in series with the load, 22Ω or more. If a series resistance cannot be used, then adding a 300Ω or less load resistor to ground or a "snubber" network may help. A snubber is a resistor in series with a capacitor, 150Ω and 100pF being typical values. The advantage of a snubber is that it does not draw DC load current.

Unterminated coaxial line loads can also cause resonances, and they should be terminated either at the far end or a series back-match resistor installed between the EL4094 and the cable.

The output stage can deliver up to 140mA into a short-circuit load, but it is only rated for a continuous 35mA. More continuous current can cause reliability problems with the on-chip metal interconnect. Video levels and loads cause no problems at all.

Noise

The EL4094 has a very simple noise characteristic: the output noise is constant (40nV/ $\sqrt{\text{Hz}}$ wideband) for all gain settings. The input-referred noise is then the output noise divided by the gain. For instance, at a gain of 50% the input noise is 40nV/ $\sqrt{\text{Hz}}/0.5$, or 80nV/ $\sqrt{\text{Hz}}$.

Bypassing

The EL4094 is fairly tolerant of power-supply bypassing, but best multiplier performance is obtained with closely connected 0.1μF ceramic capacitors. The leaded chip capacitors are good, but neither additional tantalums nor chip components are necessary. The signal inputs can oscillate locally when connected to long lines or unterminated cables.

Power Dissipation

Peak die temperature must not exceed 150°C. At this temperature, the epoxy begins to soften and becomes unstable, chemically and mechanically. This allows 75°C internal temperature rise for a 75°C ambient. The EL4094 in the 8-pin PDIP package has a thermal resistance of 87°/W, and can thus dissipate 862mW at a 75°C ambient temperature. The device draws 17mA maximum supply current, only 510mW at $\pm 15V$ supplies, and the circuit has no dissipation problems in this package.

The SO-8 surface-mount package has a 153°/W thermal resistance with the EL4094, and only 490mW can be dissipated at 75°C ambient temperature. The EL4094 thus cannot be operated with $\pm 15V$ supplies at 75°C in the surface-mount package; the supplies should be reduced to

$\pm 5V$ to $\pm 12V$ levels, especially if extra dissipation occurs when driving a load.

The EL4094 as a Level Adjust

A common use for gain controls is as an input signal leveller—a circuit that scales too-large or too-small signals to a standard amplitude. A typical situation would be to scale a variable video input by +6dB to -6dB to obtain a standard amplitude. The EL4094 cannot provide more than 0dB gain, but it can span the range of 0dB to -12dB with another amplifier gaining the output up by 6dB. The simplest way to obtain the range is to simply ground the B input and vary the gain of the signal applied to the A input. The disadvantage of this approach is that linearity degrades at low gains. By connecting the signal to the A input of the EL4094 and the signal attenuated by 12dB to the B input, the gain control offers the highest linearity possible at 0dB and -12dB extremes, and good performance between. The circuit is shown on the following page.

The EL4095 can be used to provide the required gains without the extra amplifier. In practice, the gain control is adjusted to set a standard video level regardless of the input level. The EL4583 sync-separator has a recovered amplitude output that can be used to servo the gain control voltage. Here is the curve of differential gain and phase

distortion for varying inputs, with the output set to standard video level:

FIGURE 2. DIFFERENTIAL GAIN AND PHASE OF LINEARIZED LEVEL CONTROL

The differential gain error is kept to 0.3% and the differential phase to 0.15° or better over the entire input range.

The EL4094 as an Adjustable Filter

Equalizers are used to adjust the delay or frequency response of systems. A typical use is to compensate for the high-frequency loss of a cable system ahead of the cable so as to create a flat response at the far end. A generalized scheme with the EL4094 is shown below.

FIGURE 3. +6dB to -6dB LINEARIZED LEVEL CONTROL

FIGURE 4. GENERAL ADJUSTABLE EQUALIZER

For an adjustable preemphasis filter, for instance, filter A might be an all-pass filter to compensate for the delay of filter B, a peaking filter. Fading the gain from A to B provides a variable amount of peaking, but constant delay.

The EL4094 as a Phase Modulator

To make a phase modulator, filter A might be a leading-phase network, and filter B a lagging network. The wide bandwidth of the gain-control input allows wideband phase modulation of the carrier applied to the main input. Of course, the carrier and gain inputs must not be digital but be reasonably clean sinewaves for the modulation to be accurate.

EL4094 Macromodel

This macromodel is offered to allow simulation of general EL4094 behavior. We have included these characteristics:

- Small-signal frequency response
- Output loading effects
- Input impedance
- Off-channel feedthrough
- Output impedance over frequency
- Signal path DC distortions
- V_{GAIN} I-V characteristics
- V_{GAIN} overdrive recovery delay
- 100% gain error

These will give a good range of results for various operating conditions, but the macromodel does not behave identically as the circuit in these areas:

- Temperature effects
- Signal overload effects
- Signal and $\sqrt{V_G}$ operating range
- Current-limit
- Video and high-frequency distortions
- Supply voltage effects
- Slewrate limitations
- Noise
- Power supply interactions

The macromodel's netlist is based on the Pspice simulator (copyrighted by the Microsim Company). Other simulators may not support the POLY function, which is used to implement multiplication as well as square-law nonlinearities.
