

M29W640DT M29W640DB

64 Mbit (8Mb x8 or 4Mb x16, Boot Block)
3V Supply Flash Memory

PRELIMINARY DATA

FEATURES SUMMARY

- **SUPPLY VOLTAGE**
 - $V_{CC} = 2.7V$ to $3.6V$ for Program, Erase, Read
 - $V_{PP} = 12V$ for Fast Program (optional)
- **ACCESS TIME:** 70, 90 ns
- **PROGRAMMING TIME**
 - 10 μs per Byte/Word typical
 - Double Word Programming Option
- **135 MEMORY BLOCKS**
 - 1 Boot Block and 7 Parameter Blocks, 8 KBytes each (Top or Bottom Location)
 - 127 Main Blocks, 64 KBytes each
- **PROGRAM/ERASE CONTROLLER**
 - Embedded Byte/Word Program algorithms
- **ERASE SUSPEND and RESUME MODES**
 - Read and Program another Block during Erase Suspend
- **UNLOCK BYPASS PROGRAM COMMAND**
 - Faster Production/Batch Programming
- **V_{PP}/\overline{WP} Pin for FAST PROGRAM and WRITE PROTECT**
- **TEMPORARY BLOCK UNPROTECTION MODE**
- **COMMON FLASH INTERFACE**
 - 64-bit Security Code
- **EXTENDED MEMORY BLOCK**
 - Extra block used as security block or to store additional information
- **LOW POWER CONSUMPTION**
 - Standby and Automatic Standby
- **100,000 PROGRAM/ERASE CYCLES per BLOCK**
- **ELECTRONIC SIGNATURE**
 - Manufacturer Code: 0020h
 - Top Device Code M29W640DT: 22DEh
 - Bottom Device Code M29W640DB: 22DFh

SUMMARY DESCRIPTION

The M29W640D is a 64 Mbit (8Mb x8 or 4Mb x16) non-volatile memory that can be read, erased and reprogrammed. These operations can be performed using a single low voltage (2.7 to 3.6V) supply. On power-up the memory defaults to its Read mode where it can be read in the same way as a ROM or EPROM.

The memory is divided into blocks that can be erased independently so it is possible to preserve valid data while old data is erased. Blocks can be protected in units of 256 KByte (generally groups of four 64 KByte blocks), to prevent accidental Program or Erase commands from modifying the memory. Program and Erase commands are written to the Command Interface of the memory. An on-chip Program/Erase Controller simplifies the process of programming or erasing the memory by taking care of all of the special operations that are required to update the memory contents. The end of a program or erase operation can be detected and any error conditions identified. The command set required to control the memory is consistent with JEDEC standards.

The device features an asymmetrical blocked architecture. The device has an array of 135 blocks:

- 8 Parameter Blocks of 8 KBytes each (or 4 KWords each)
- 127 Main Blocks of 64 KBytes each (or 32 KWords each)

M29W640DT has the Parameter Blocks at the top of the memory address space while the M29W640DB locates the Parameter Blocks starting from the bottom.

The M29W640D has an extra block, the Extended Block, (of 32 KWords in x16 mode or of 64 KBytes in x8 mode) that can be accessed using a dedicated command. The Extended Block can be protected and so is useful for storing security information. However the protection is not reversible, once protected the protection cannot be undone.

Chip Enable, Output Enable and Write Enable signals control the bus operation of the memory. They allow simple connection to most microprocessors, often without additional logic.

The V_{PP}/\overline{WP} signal is used to enable faster programming of the device, enabling double word programming. If this signal is held at V_{SS} , the boot block, and its adjacent parameter block, are protected from program and erase operations.

The memory is delivered with all the bits erased (set to 1).

SIGNAL DESCRIPTIONS

See Figure 2, Logic Diagram, and Table 1, Signal Names, for a brief overview of the signals connected to this device.

Address Inputs (A0-A21). The Address Inputs select the cells in the memory array to access during Bus Read operations. During Bus Write operations they control the commands sent to the Command Interface of the Program/Erase Controller.

Data Inputs/Outputs (DQ0-DQ7). The Data I/O outputs the data stored at the selected address during a Bus Read operation. During Bus Write operations they represent the commands sent to the Command Interface of the Program/Erase Controller.

Data Inputs/Outputs (DQ8-DQ14). The Data I/O outputs the data stored at the selected address during a Bus Read operation when $\overline{\text{BYTE}}$ is High, V_{IH} . When $\overline{\text{BYTE}}$ is Low, V_{IL} , these pins are not used and are high impedance. During Bus Write operations the Command Register does not use these bits. When reading the Status Register these bits should be ignored.

Data Input/Output or Address Input (DQ15A-1). When $\overline{\text{BYTE}}$ is High, V_{IH} , this pin behaves as a Data Input/Output pin (as DQ8-DQ14). When $\overline{\text{BYTE}}$ is Low, V_{IL} , this pin behaves as an address pin; DQ15A-1 Low will select the LSB of the addressed Word, DQ15A-1 High will select the MSB. Throughout the text consider references to the Data Input/Output to include this pin when $\overline{\text{BYTE}}$ is High and references to the Address Inputs to include this pin when $\overline{\text{BYTE}}$ is Low except when stated explicitly otherwise.

Chip Enable ($\overline{\text{E}}$). The Chip Enable, $\overline{\text{E}}$, activates the memory, allowing Bus Read and Bus Write operations to be performed. When Chip Enable is High, V_{IH} , all other pins are ignored.

Output Enable ($\overline{\text{G}}$). The Output Enable, $\overline{\text{G}}$, controls the Bus Read operation of the memory.

Write Enable ($\overline{\text{W}}$). The Write Enable, $\overline{\text{W}}$, controls the Bus Write operation of the memory's Command Interface.

V_{PP} /Write Protect ($V_{PP}/\overline{\text{WP}}$). The V_{PP} /Write Protect pin provides two functions. The V_{PP} function allows the memory to use an external high voltage power supply to reduce the time required for Unlock Bypass Program operations. The Write Protect function provides a hardware method of protecting the two outermost boot blocks. The V_{PP} /Write Protect pin must not be left floating or unconnected.

When V_{PP} /Write Protect is Low, V_{IL} , the memory protects the two outermost boot blocks; Program

and Erase operations in this block are ignored while V_{PP} /Write Protect is Low.

When V_{PP} /Write Protect is High, V_{IH} , the memory reverts to the previous protection status of the two outermost boot blocks. Program and Erase operations can now modify the data in the two outermost boot blocks unless the block is protected using Block Protection.

When V_{PP} /Write Protect is raised to V_{PP} the memory automatically enters the Unlock Bypass mode. When V_{PP} /Write Protect returns to V_{IH} or V_{IL} normal operation resumes. During Unlock Bypass Program operations the memory draws I_{PP} from the pin to supply the programming circuits. See the description of the Unlock Bypass command in the Command Interface section. The transitions from V_{IH} to V_{PP} and from V_{PP} to V_{IH} must be slower than t_{VHVPP} , see Figure 13.

Never raise V_{PP} /Write Protect to V_{PP} from any mode except Read mode, otherwise the memory may be left in an indeterminate state.

A 0.1 μF capacitor should be connected between the V_{PP} /Write Protect pin and the V_{SS} Ground pin to decouple the current surges from the power supply. The PCB track widths must be sufficient to carry the currents required during Unlock Bypass Program, I_{PP} .

Reset/Block Temporary Unprotect ($\overline{\text{RP}}$). The Reset/Block Temporary Unprotect pin can be used to apply a Hardware Reset to the memory or to temporarily unprotect all Blocks that have been protected.

Note that if $V_{PP}/\overline{\text{WP}}$ is at V_{IL} , then the two outermost boot blocks will remain protected even if $\overline{\text{RP}}$ is at V_{ID} .

A Hardware Reset is achieved by holding Reset/Block Temporary Unprotect Low, V_{IL} , for at least t_{LPX} . After Reset/Block Temporary Unprotect goes High, V_{IH} , the memory will be ready for Bus Read and Bus Write operations after t_{PHEL} or t_{RHEL} , whichever occurs last. See the Ready/Busy Output section, Table 15 and Figure 12, Reset/Block Temporary Unprotect AC Characteristics, for more details.

Holding $\overline{\text{RP}}$ at V_{ID} will temporarily unprotect the protected Blocks in the memory. Program and Erase operations on all blocks will be possible. The transition from V_{IH} to V_{ID} must be slower than t_{PHPHH} .

Ready/Busy Output ($\overline{\text{RB}}$). The Ready/Busy pin is an open-drain output that can be used to identify when the device is performing a Program or Erase operation. During Program or Erase operations Ready/Busy is Low, V_{OL} . Ready/Busy is high-impedance during Read mode, Auto Select mode and Erase Suspend mode.

After a Hardware Reset, Bus Read and Bus Write operations cannot begin until Ready/Busy becomes high-impedance. See Table 15 and Figure 12, Reset/Block Temporary Unprotect AC Characteristics.

The use of an open-drain output allows the Ready/Busy pins from several memories to be connected to a single pull-up resistor. A Low will then indicate that one, or more, of the memories is busy.

Byte/Word Organization Select ($\overline{\text{BYTE}}$). The Byte/Word Organization Select pin is used to switch between the x8 and x16 Bus modes of the memory. When Byte/Word Organization Select is Low, V_{IL} , the memory is in x8 mode, when it is High, V_{IH} , the memory is in x16 mode.

V_{CC} Supply Voltage (2.7V to 3.6V). V_{CC} provides the power supply for all operations (Read, Program and Erase).

The Command Interface is disabled when the V_{CC} Supply Voltage is less than the Lockout Voltage, V_{LKO}. This prevents Bus Write operations from accidentally damaging the data during power up, power down and power surges. If the Program/Erase Controller is programming or erasing during this time then the operation aborts and the memory contents being altered will be invalid.

A 0.1μF capacitor should be connected between the V_{CC} Supply Voltage pin and the V_{SS} Ground pin to decouple the current surges from the power supply. The PCB track widths must be sufficient to carry the currents required during Program and Erase operations, I_{CC3}.

V_{SS} Ground. V_{SS} is the reference for all voltage measurements. The device features two V_{SS} pins which must be both connected to the system ground.

BUS OPERATIONS

There are five standard bus operations that control the device. These are Bus Read, Bus Write, Output Disable, Standby and Automatic Standby. See Table 2 and Table 3, Bus Operations, for a summary. Typically glitches of less than 5ns on Chip Enable or Write Enable are ignored by the memory and do not affect bus operations.

Bus Read. Bus Read operations read from the memory cells, or specific registers in the Command Interface. A valid Bus Read operation involves setting the desired address on the Address Inputs, applying a Low signal, V_{IL} , to Chip Enable and Output Enable and keeping Write Enable High, V_{IH} . The Data Inputs/Outputs will output the value, see Figure 9, Read Mode AC Waveforms, and Table 12, Read AC Characteristics, for details of when the output becomes valid.

Bus Write. Bus Write operations write to the Command Interface. A valid Bus Write operation begins by setting the desired address on the Address Inputs. The Address Inputs are latched by the Command Interface on the falling edge of Chip Enable or Write Enable, whichever occurs last. The Data Inputs/Outputs are latched by the Command Interface on the rising edge of Chip Enable or Write Enable, whichever occurs first. Output Enable must remain High, V_{IH} , during the whole Bus Write operation. See Figure 10 and Figure 11, Write AC Waveforms, and Table 13 and Table 14, Write AC Characteristics, for details of the timing requirements.

Output Disable. The Data Inputs/Outputs are in the high impedance state when Output Enable is High, V_{IH} .

Standby. When Chip Enable is High, V_{IH} , the memory enters Standby mode and the Data Inputs/Outputs pins are placed in the high-impedance state. To reduce the Supply Current to the Standby Supply Current, I_{CC2} , Chip Enable should

be held within $V_{CC} \pm 0.2V$. For the Standby current level see Table 11, DC Characteristics.

During program or erase operations the memory will continue to use the Program/Erase Supply Current, I_{CC3} , for Program or Erase operations until the operation completes.

Automatic Standby. If CMOS levels ($V_{CC} \pm 0.2V$) are used to drive the bus and the bus is inactive for 300ns or more the memory enters Automatic Standby where the internal Supply Current is reduced to the Standby Supply Current, I_{CC2} . The Data Inputs/Outputs will still output data if a Bus Read operation is in progress.

Special Bus Operations

Additional bus operations can be performed to read the Electronic Signature and also to apply and remove Block Protection. These bus operations are intended for use by programming equipment and are not usually used in applications. They require V_{ID} to be applied to some pins.

Electronic Signature. The memory has two codes, the manufacturer code and the device code, that can be read to identify the memory. These codes can be read by applying the signals listed in Table 2 and Table 3, Bus Operations.

Block Protect and Chip Unprotect. Groups of blocks can be protected against accidental Program or Erase. The Protection Groups are shown in Appendix A, Table 19 and Table 20, Block Addresses. The whole chip can be unprotected to allow the data inside the blocks to be changed.

The V_{PP} /Write Protect pin can be used to protect the two outermost boot blocks. When V_{PP} /Write Protect is at V_{IL} the two outermost boot blocks are protected and remain protected regardless of the Block Protection Status or the Reset/Block Temporary Unprotect pin status.

Block Protect and Chip Unprotect operations are described in Appendix D.

Table 2. Bus Operations, $\overline{\text{BYTE}} = V_{\text{IL}}$

Operation	$\overline{\text{E}}$	$\overline{\text{G}}$	$\overline{\text{W}}$	Address Inputs DQ15A–1, A0–A21	Data Inputs/Outputs

Note: X = V_{IL} or V_{IH} .

COMMAND INTERFACE

All Bus Write operations to the memory are interpreted by the Command Interface. Commands consist of one or more sequential Bus Write operations. Failure to observe a valid sequence of Bus Write operations will result in the memory returning to Read mode. The long command sequences are imposed to maximize data security.

The address used for the commands changes depending on whether the memory is in 16-bit or 8-bit mode. See either Table 4, or Table 5, depending on the configuration that is being used, for a summary of the commands.

Read/Reset Command.

The Read/Reset command returns the memory to its Read mode where it behaves like a ROM or EPROM. It also resets the errors in the Status Register. Either one or three Bus Write operations can be used to issue the Read/Reset command.

The Read/Reset command can be issued, between Bus Write cycles before the start of a program or erase operation, to return the device to read mode. If the Read/Reset command is issued during the timeout of a Block erase operation then the memory will take up to 10 μ s to abort. During the abort period no valid data can be read from the memory. The Read/Reset command will not abort an Erase operation when issued while in Erase Suspend.

Auto Select Command.

The Auto Select command is used to read the Manufacturer Code, the Device Code, the Block Protection Status and the Extended Memory Block Verify Code. Three consecutive Bus Write operations are required to issue the Auto Select command. Once the Auto Select command is issued the memory remains in Auto Select mode until a Read/Reset command is issued. Read CFI Query and Read/Reset commands are accepted in Auto Select mode, all other commands are ignored.

In Auto Select mode the Manufacturer Code can be read using a Bus Read operation with A0 = V_{IL} and A1 = V_{IL}. The other address bits may be set to either V_{IL} or V_{IH}. The Manufacturer Code for ST-Microelectronics is 0020h.

The Device Code can be read using a Bus Read operation with A0 = V_{IH} and A1 = V_{IL}. The other address bits may be set to either V_{IL} or V_{IH}. The Device Code for the M29W640DT is 22DEh and for the M29W640DB is 22DFh.

The Block Protection Status of each block can be read using a Bus Read operation with A0 = V_{IL}, A1 = V_{IH}, and A12-A21 specifying the address of the block. The other address bits may be set to either V_{IL} or V_{IH}. If the addressed block is protected then 01h is output on Data Inputs/Outputs DQ0-DQ7, otherwise 00h is output.

Read CFI Query Command

The Read CFI Query Command is used to read data from the Common Flash Interface (CFI) Memory Area. This command is valid when the device is in the Read Array mode, or when the device is in Autoselected mode.

One Bus Write cycle is required to issue the Read CFI Query Command. Once the command is issued subsequent Bus Read operations read from the Common Flash Interface Memory Area.

The Read/Reset command must be issued to return the device to the previous mode (the Read Array mode or Autoselected mode). A second Read/Reset command would be needed if the device is to be put in the Read Array mode from Autoselected mode.

See Appendix B, Table 21 to Table 26 for details on the information contained in the Common Flash Interface (CFI) memory area.

Program Command.

The Program command can be used to program a value to one address in the memory array at a time. The command requires four Bus Write operations, the final write operation latches the address and data, and starts the Program/Erase Controller.

If the address falls in a protected block then the Program command is ignored, the data remains unchanged. The Status Register is never read and no error condition is given.

During the program operation the memory will ignore all commands. It is not possible to issue any command to abort or pause the operation. Typical program times are given in Table 6. Bus Read operations during the program operation will output the Status Register on the Data Inputs/Outputs. See the section on the Status Register for more details.

After the program operation has completed the memory will return to the Read mode, unless an error has occurred. When an error occurs the memory will continue to output the Status Register. A Read/Reset command must be issued to reset the error condition and return to Read mode.

Note that the Program command cannot change a bit set at '0' back to '1'. One of the Erase Commands must be used to set all the bits in a block or in the whole memory from '0' to '1'.

Fast Program Commands

There are two Fast Program commands available to improve the programming throughput, by writing several adjacent words or bytes in parallel. The Quadruple Byte Program command is available for x8 operations, while the Double Word Program command is available for x16 operations.

Quadruple Byte Program Command. The Quadruple Byte Program command is used to write a page of four adjacent Bytes in parallel. The four bytes must differ only for addresses A0, DQ15A-1. Five bus write cycles are necessary to issue the Quadruple Byte Program command.

- The first bus cycle sets up the Quadruple Byte Program Command.
- The second bus cycle latches the Address and the Data of the first byte to be written.
- The third bus cycle latches the Address and the Data of the second byte to be written.
- The fourth bus cycle latches the Address and the Data of the third byte to be written.
- The fifth bus cycle latches the Address and the Data of the fourth byte to be written and starts the Program/Erase Controller.

Double Word Program Command. The Double Word Program command is used to write a page of two adjacent words in parallel. The two words must differ only for the address A0.

Three bus write cycles are necessary to issue the Double Word Program command.

- The first bus cycle sets up the Double Word Program Command.
- The second bus cycle latches the Address and the Data of the first word to be written.
- The third bus cycle latches the Address and the Data of the second word to be written and starts the Program/Erase Controller.

Only one bank can be programmed at any one time. The other bank must be in Read mode or Erase Suspend.

Programming should not be attempted when V_{PP} is not at V_{PPH} .

After programming has started, Bus Read operations in the Bank being programmed output the Status Register content, while Bus Read operations to the other Bank output the contents of the memory array.

After the program operation has completed the memory will return to the Read mode, unless an error has occurred. When an error occurs Bus Read operations to the Bank where the command was issued will continue to output the Status Register. A Read/Reset command must be issued to reset the error condition and return to Read mode.

Note that the Fast Program commands cannot change a bit set at '0' back to '1'. One of the Erase Commands must be used to set all the bits in a block or in the whole memory from '0' to '1'.

Typical Program times are given in Table 6, Program, Erase Times and Program, Erase Endurance Cycles.

Unlock Bypass Command.

The Unlock Bypass command is used in conjunction with the Unlock Bypass Program command to program the memory faster than with the standard program commands. When the cycle time to the device is long (as with some EPROM programmers) considerable time saving can be made by using these commands. Three Bus Write operations are required to issue the Unlock Bypass command.

Once the Unlock Bypass command has been issued the memory will only accept the Unlock Bypass Program command and the Unlock Bypass Reset command. The memory can be read as if in Read mode.

When V_{PP} is applied to the V_{PP} /Write Protect pin the memory automatically enters the Unlock Bypass mode and the Unlock Bypass Program command can be issued immediately.

Unlock Bypass Program Command.

The Unlock Bypass command is used in conjunction with the Unlock Bypass Program command to program the memory. When the cycle time to the device is long (as with some EPROM programmers) considerable time saving can be made by using these commands. Three Bus Write operations are required to issue the Unlock Bypass command.

Once the Unlock Bypass command has been issued the memory will only accept the Unlock Bypass Program command and the Unlock Bypass Reset command. The memory can be read as if in Read mode.

The memory offers accelerated program operations through the V_{PP} /Write Protect pin. When the system asserts V_{PP} on the V_{PP} /Write Protect pin, the memory automatically enters the Unlock Bypass mode. The system may then write the two-cycle Unlock Bypass program command sequence. The memory uses the higher voltage on the V_{PP} /Write Protect pin, to accelerate the Unlock Bypass Program operation.

Never raise V_{PP} /Write Protect to V_{PP} from any mode except Read mode, otherwise the memory may be left in an indeterminate state.

Unlock Bypass Reset Command.

The Unlock Bypass Reset command can be used to return to Read/Reset mode from Unlock Bypass Mode. Two Bus Write operations are required to issue the Unlock Bypass Reset command. Read/Reset command does not exit from Unlock Bypass Mode.

Chip Erase Command.

The Chip Erase command can be used to erase the entire chip. Six Bus Write operations are re-

quired to issue the Chip Erase Command and start the Program/Erase Controller.

If any blocks are protected then these are ignored and all the other blocks are erased. If all of the blocks are protected the Chip Erase operation appears to start but will terminate within about 100 μ s, leaving the data unchanged. No error condition is given when protected blocks are ignored.

During the erase operation the memory will ignore all commands, including the Erase Suspend command. It is not possible to issue any command to abort the operation. Typical chip erase times are given in Table 6. All Bus Read operations during the Chip Erase operation will output the Status Register on the Data Inputs/Outputs. See the section on the Status Register for more details.

After the Chip Erase operation has completed the memory will return to the Read Mode, unless an error has occurred. When an error occurs the memory will continue to output the Status Register. A Read/Reset command must be issued to reset the error condition and return to Read Mode.

The Chip Erase Command sets all of the bits in unprotected blocks of the memory to '1'. All previous data is lost.

Block Erase Command.

The Block Erase command can be used to erase a list of one or more blocks. Six Bus Write operations are required to select the first block in the list. Each additional block in the list can be selected by repeating the sixth Bus Write operation using the address of the additional block. The Block Erase operation starts the Program/Erase Controller about 50 μ s after the last Bus Write operation. Once the Program/Erase Controller starts it is not possible to select any more blocks. Each additional block must therefore be selected within 50 μ s of the last block. The 50 μ s timer restarts when an additional block is selected. The Status Register can be read after the sixth Bus Write operation. See the Status Register section for details on how to identify if the Program/Erase Controller has started the Block Erase operation.

If any selected blocks are protected then these are ignored and all the other selected blocks are erased. If all of the selected blocks are protected the Block Erase operation appears to start but will terminate within about 100 μ s, leaving the data unchanged. No error condition is given when protected blocks are ignored.

During the Block Erase operation the memory will ignore all commands except the Erase Suspend command. Typical block erase times are given in Table 6. All Bus Read operations during the Block Erase operation will output the Status Register on the Data Inputs/Outputs. See the section on the Status Register for more details.

After the Block Erase operation has completed the memory will return to the Read Mode, unless an error has occurred. When an error occurs the memory will continue to output the Status Register. A Read/Reset command must be issued to reset the error condition and return to Read mode. The Block Erase Command sets all of the bits in the unprotected selected blocks to '1'. All previous data in the selected blocks is lost.

Erase Suspend Command.

The Erase Suspend Command may be used to temporarily suspend a Block Erase operation and return the memory to Read mode. The command requires one Bus Write operation.

The Program/Erase Controller will suspend within the Erase Suspend Latency time of the Erase Suspend Command being issued. Once the Program/Erase Controller has stopped the memory will be set to Read mode and the Erase will be suspended. If the Erase Suspend command is issued during the period when the memory is waiting for an additional block (before the Program/Erase Controller starts) then the Erase is suspended immediately and will start immediately when the Erase Resume Command is issued. It is not possible to select any further blocks to erase after the Erase Resume.

During Erase Suspend it is possible to Read and Program cells in blocks that are not being erased; both Read and Program operations behave as normal on these blocks. If any attempt is made to program in a protected block or in the suspended block then the Program command is ignored and the data remains unchanged. The Status Register is not read and no error condition is given. Reading from blocks that are being erased will output the Status Register.

It is also possible to issue the Auto Select, Read CFI Query and Unlock Bypass commands during an Erase Suspend. The Read/Reset command must be issued to return the device to Read Array mode before the Resume command will be accepted.

Erase Resume Command.

The Erase Resume command must be used to restart the Program/Erase Controller after an Erase Suspend. The device must be in Read Array mode before the Resume command will be accepted. An erase can be suspended and resumed more than once.

Enter Extended Block Command

The device has an extra 64 KByte block (Extended Block) that can only be accessed using the Enter Extended Block command. Three Bus write cycles are required to issue the Extended Block command. Once the command has been issued the device enters Extended Block mode where all Bus

Read or Write operations to the Boot Block addresses access the Extended Block. The Extended Block (with the same address as the Boot Blocks) cannot be erased, and can be treated as one-time programmable (OTP) memory. In Extended Block mode the Boot Blocks are not accessible.

To exit from the Extended Block mode the Exit Extended Block command must be issued.

The Extended Block can be protected, however once protected the protection cannot be undone.

Exit Extended Block Command

The Exit Extended Block command is used to exit from the Extended Block mode and return the de-

vice to Read mode. Four Bus Write operations are required to issue the command.

Block Protect and Chip Unprotect Commands

Groups of blocks can be protected against accidental Program or Erase. The Protection Groups are shown in Appendix A, Table 19 and Table 20, Block Addresses. The whole chip can be unprotected to allow the data inside the blocks to be changed.

Block Protect and Chip Unprotect operations are described in Appendix D.

Table 4. Commands, 16-bit mode, $\overline{\text{BYTE}} = V_{IH}$

Command	Length	Bus Write Operations											
		1st		2nd		3rd		4th		5th		6th	
		Addr	Data	Addr	Data	Addr	Data	Addr	Data	Addr	Data	Addr	Data
Read/Reset	1	X	F0										
	3	555	AA	2AA	55	X	F0						
Auto Select	3	555	AA	2AA	55	555	90						
Program	4	555	AA	2AA	55	555	A0	PA	PD				
Double Word Program	3	555	50	PA0	PD0	PA1	PD1						
Unlock Bypass	3	555	AA	2AA	55	555	20						
Unlock Bypass Program	2	X	A0	PA	PD								
Unlock Bypass Reset	2	X	90	X	00								
Chip Erase	6	555	AA	2AA	55	555	80	555	AA	2AA	55	555	10
Block Erase	6+	555	AA	2AA	55	555	80	555	AA	2AA	55	BA	30
Erase Suspend	1	X	B0										
Erase Resume	1	X	30										
Read CFI Query	1	55	98										
Enter Extended Block	3	555	AA	2AA	55	555	88						
Exit Extended Block	4	555	AA	2AA	55	555	90	X	00				

Note: X Don't Care, PA Program Address, PD Program Data, BA Any address in the Block. All values in the table are in hexadecimal.

The Command Interface only uses A-1, A0-A10 and DQ0-DQ7 to verify the commands; A11-A20, DQ8-DQ14 and DQ15 are Don't Care. DQ15A-1 is A-1 when $\overline{\text{BYTE}}$ is V_{IL} or DQ15 when $\overline{\text{BYTE}}$ is V_{IH} .

Table 5. Commands, 8-bit mode, $\overline{\text{BYTE}} = V_{\text{IL}}$

Command	Length	Bus Write Operations											
		1st		2nd		3rd		4th		5th		6th	
		Add	Data	Add	Data	Add	Data	Add	Data	Add	Data	Add	Data
Read/Reset	1	X	F0										
	3	AAA	AA	555	55	X	F0						
Auto Select	3	AAA	AA	555	55	AAA	90						
Program	4	AAA	AA	555	55	AAA	A0	PA	PD				
Quadruple Byte Program	5	AAA	55	PA0	PD0	PA1	PD1	PA2	PD2	PA3	PD3		
Unlock Bypass	3	AAA	AA	555	55	AAA	20						
Unlock Bypass Program	2	X	A0	PA	PD								
Unlock Bypass Reset	2	X	90	X	00								
Chip Erase	6	AAA	AA	555	55	AAA	80	AAA	AA	555	55	AAA	10
Block Erase	6+	AAA	AA	555	55	AAA	80	AAA	AA	555	55	BA	30
Erase Suspend	1	X	B0										
Erase Resume	1	X	30										
Read CFI Query	1	AA	98										
Enter Extended Block	3	AAA	AA	555	55	AAA	88						
Exit Extended Block	4	AAA	AA	555	55	AAA	90	X	00				

Note: X Don't Care, PA Program Address, PD Program Data, BA Any address in the Block. All values in the table are in hexadecimal.

The Command Interface only uses A–1, A0-A10 and DQ0-DQ7 to verify the commands; A11-A20, DQ8-DQ14 and DQ15 are Don't Care. DQ15A–1 is A–1 when $\overline{\text{BYTE}}$ is V_{IL} or DQ15 when $\overline{\text{BYTE}}$ is V_{IH} .

Table 6. Program, Erase Times and Program, Erase Endurance Cycles

Parameter	Min	Typ ^(1, 2)	Max ⁽²⁾	Unit
Chip Erase		80	400 ⁽³⁾	s
Block Erase (64 KBytes)		0.8	6 ⁽⁴⁾	s
Erase Suspend Latency Time			50 ⁽⁴⁾	μs
Program (Byte or Word)		10	200 ⁽³⁾	μs
Double Word Program (Byte or Word)		10	200 ⁽³⁾	μs
Chip Program (Byte by Byte)		80	400 ⁽³⁾	s
Chip Program (Word by Word)		40	200 ⁽³⁾	s
Chip Program (Quadruple Byte or Double Word)		20	100 ⁽³⁾	s
Program/Erase Cycles (per Block)	100,000			cycles
Data Retention	20			years

Note: 1. Typical values measured at room temperature and nominal voltages.

2. Sampled, but not 100% tested.

3. Maximum value measured at worst case conditions for both temperature and V_{CC} after 100,00 program/erase cycles.

4. Maximum value measured at worst case conditions for both temperature and V_{CC} .

STATUS REGISTER

Bus Read operations from any address always read the Status Register during Program and Erase operations. It is also read during Erase Suspend when an address within a block being erased is accessed.

The bits in the Status Register are summarized in Table 7, Status Register Bits.

Data Polling Bit (DQ7). The Data Polling Bit can be used to identify whether the Program/Erase Controller has successfully completed its operation or if it has responded to an Erase Suspend. The Data Polling Bit is output on DQ7 when the Status Register is read.

During Program operations the Data Polling Bit outputs the complement of the bit being programmed to DQ7. After successful completion of the Program operation the memory returns to Read mode and Bus Read operations from the address just programmed output DQ7, not its complement.

During Erase operations the Data Polling Bit outputs '0', the complement of the erased state of DQ7. After successful completion of the Erase operation the memory returns to Read Mode.

In Erase Suspend mode the Data Polling Bit will output a '1' during a Bus Read operation within a block being erased. The Data Polling Bit will change from a '0' to a '1' when the Program/Erase Controller has suspended the Erase operation.

Figure 5, Data Polling Flowchart, gives an example of how to use the Data Polling Bit. A Valid Address is the address being programmed or an address within the block being erased.

Toggle Bit (DQ6). The Toggle Bit can be used to identify whether the Program/Erase Controller has successfully completed its operation or if it has responded to an Erase Suspend. The Toggle Bit is output on DQ6 when the Status Register is read.

During Program and Erase operations the Toggle Bit changes from '0' to '1' to '0', etc., with successive Bus Read operations at any address. After successful completion of the operation the memory returns to Read mode.

During Erase Suspend mode the Toggle Bit will output when addressing a cell within a block being erased. The Toggle Bit will stop toggling when the Program/Erase Controller has suspended the Erase operation.

Figure 6, Data Toggle Flowchart, gives an example of how to use the Data Toggle Bit.

Error Bit (DQ5). The Error Bit can be used to identify errors detected by the Program/Erase Controller. The Error Bit is set to '1' when a Program, Block Erase or Chip Erase operation fails to write the correct data to the memory. If the Error Bit is set a Read/Reset command must be issued before other commands are issued. The Error bit is output on DQ5 when the Status Register is read.

Note that the Program command cannot change a bit set to '0' back to '1' and attempting to do so will set DQ5 to '1'. A Bus Read operation to that address will show the bit is still '0'. One of the Erase commands must be used to set all the bits in a block or in the whole memory from '0' to '1'.

Erase Timer Bit (DQ3). The Erase Timer Bit can be used to identify the start of Program/Erase Controller operation during a Block Erase command. Once the Program/Erase Controller starts erasing the Erase Timer Bit is set to '1'. Before the Program/Erase Controller starts the Erase Timer Bit is set to '0' and additional blocks to be erased may be written to the Command Interface. The Erase Timer Bit is output on DQ3 when the Status Register is read.

Alternative Toggle Bit (DQ2). The Alternative Toggle Bit can be used to monitor the Program/Erase controller during Erase operations. The Alternative Toggle Bit is output on DQ2 when the Status Register is read.

During Chip Erase and Block Erase operations the Toggle Bit changes from '0' to '1' to '0', etc., with successive Bus Read operations from addresses within the blocks being erased. A protected block is treated the same as a block not being erased. Once the operation completes the memory returns to Read mode.

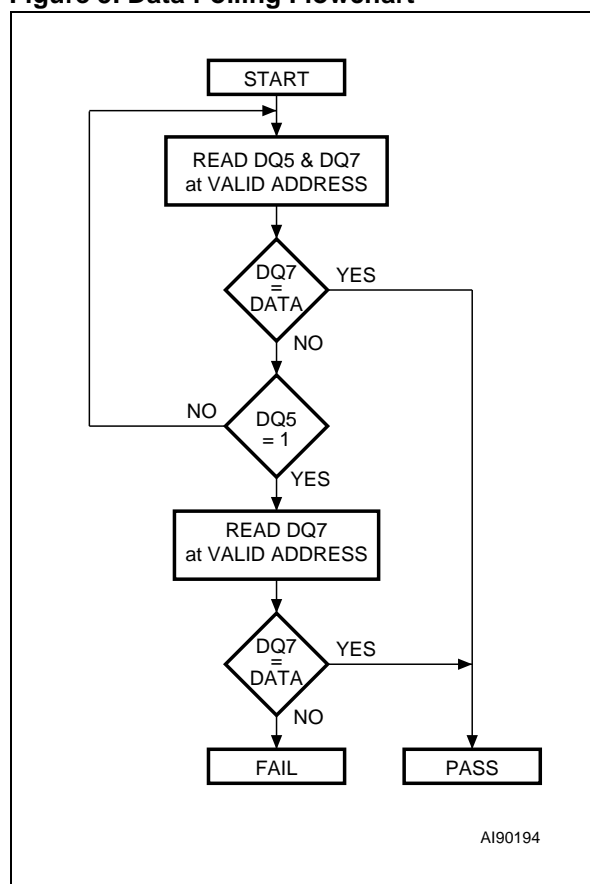

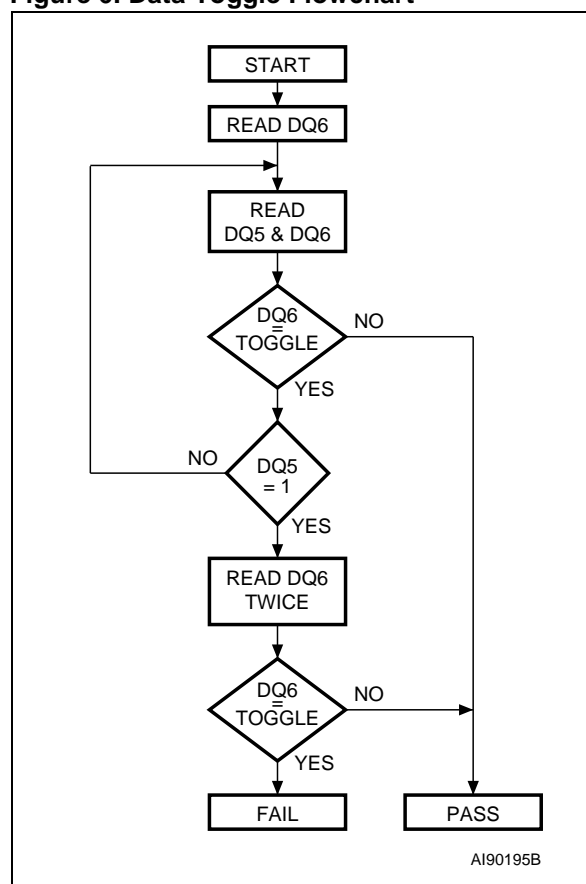

During Erase Suspend the Alternative Toggle Bit changes from '0' to '1' to '0', etc. with successive Bus Read operations from addresses within the blocks being erased. Bus Read operations to addresses within blocks not being erased will output the memory cell data as if in Read mode.

After an Erase operation that causes the Error Bit to be set the Alternative Toggle Bit can be used to identify which block or blocks have caused the error. The Alternative Toggle Bit changes from '0' to '1' to '0', etc. with successive Bus Read Operations from addresses within blocks that have not erased correctly. The Alternative Toggle Bit does not change if the addressed block has erased correctly.

Table 7. Status Register Bits

Operation	Address	DQ7	DQ6	DQ5	DQ3	DQ2	R \overline{B}
Program	Any Address	$\overline{DQ7}$	Toggle	0	–	–	0
Program During Erase Suspend	Any Address	$\overline{DQ7}$	Toggle	0	–	–	0
Program Error	Any Address	$\overline{DQ7}$	Toggle	1	–	–	0
Chip Erase	Any Address	0	Toggle	0	1	Toggle	0
Block Erase before timeout	Erasing Block	0	Toggle	0	0	Toggle	0
	Non-Erasing Block	0	Toggle	0	0	No Toggle	0
Block Erase	Erasing Block	0	Toggle	0	1	Toggle	0
	Non-Erasing Block	0	Toggle	0	1	No Toggle	0
Erase Suspend	Erasing Block	1	No Toggle	0	–	Toggle	1
	Non-Erasing Block	Data read as normal					1
Erase Error	Good Block Address	0	Toggle	1	1	No Toggle	0
	Faulty Block Address	0	Toggle	1	1	Toggle	0

Note: Unspecified data bits should be ignored.

Figure 5. Data Polling Flowchart**Figure 6. Data Toggle Flowchart**

MAXIMUM RATING

Stressing the device above the rating listed in the Absolute Maximum Ratings table may cause permanent damage to the device. Exposure to Absolute Maximum Rating conditions for extended periods may affect device reliability. These are stress ratings only and operation of the device at

these or any other conditions above those indicated in the Operating sections of this specification is not implied. Refer also to the STMicroelectronics SURE Program and other relevant quality documents.

Table 8. Absolute Maximum Ratings

Symbol	Parameter	Min	Max	Unit
T _{BIAS}	Temperature Under Bias	−50	125	°C
T _{STG}	Storage Temperature	−65	150	°C
V _{IO}	Input or Output Voltage ^(1,2)	−0.6	V _{CC} +0.6	V
V _{CC}	Supply Voltage	−0.6	4	V
V _{ID}	Identification Voltage	−0.6	13.5	V
V _{PP} ⁽³⁾	Program Voltage	−0.6	13.5	V

Note: 1. Minimum voltage may undershoot to −2V during transition and for less than 20ns during transitions.
2. Maximum voltage may overshoot to V_{CC} +2V during transition and for less than 20ns during transitions.
3. V_{PP} must not remain at 12V for more than a total of 80hrs.

DC AND AC PARAMETERS

This section summarizes the operating and measurement conditions, and the DC and AC characteristics of the device. The parameters in the DC and AC Characteristic tables that follow are derived from tests performed under the Measure-

ment Conditions summarized in the relevant tables. Designers should check that the operating conditions in their circuit match the measurement conditions when relying on the quoted parameters.

Table 9. Operating and AC Measurement Conditions

Parameter	M29W640D				Unit
	70		90		
	Min	Max	Min	Max	
V _{CC} Supply Voltage	3.0	3.6	2.7	3.6	V
Ambient Operating Temperature	−40	85	−40	85	°C

Note: 1. Used as the Extended Block Addresses in Extended Block mode.

APPENDIX B. COMMON FLASH INTERFACE (CFI)

The Common Flash Interface is a JEDEC approved, standardized data structure that can be read from the Flash memory device. It allows a system software to query the device to determine various electrical and timing parameters, density information and functions supported by the memory. The system can interface easily with the device, enabling the software to upgrade itself when necessary.

When the CFI Query Command is issued the device enters CFI Query mode and the data structure is read from the memory. Table 21 to Table 26 show the addresses used to retrieve the data.

The CFI data structure also contains a security area where a 64 bit unique security number is written (see Table 26, Security Code Area). This area can be accessed only in Read mode by the final user. It is impossible to change the security number after it has been written by ST.

Table 21. Query Structure Overview

Address		Sub-section Name	Description
x16	x8		
10h	20h	CFI Query Identification String	Command set ID and algorithm data offset
1Bh	36h	System Interface Information	Device timing & voltage information
27h	4Eh	Device Geometry Definition	Flash device layout
40h	80h	Primary Algorithm-specific Extended Query table	Additional information specific to the Primary Algorithm (optional)
61h	C2h	Security Code Area	64 bit unique device number

Note: Query data are always presented on the lowest order data outputs.

Table 22. CFI Query Identification String

Address		Data	Description	Value
x16	x8			
10h	20h	0051h	Query Unique ASCII String "QRY"	"Q"
11h	22h	0052h		"R"
12h	24h	0059h		"Y"
13h	26h	0002h	Primary Algorithm Command Set and Control Interface ID code 16 bit ID code defining a specific algorithm	AMD Compatible
14h	28h	0000h		
15h	2Ah	0040h	Address for Primary Algorithm extended Query table (see Table 25)	P = 40h
16h	2Ch	0000h		
17h	2Eh	0000h	Alternate Vendor Command Set and Control Interface ID Code second vendor - specified algorithm supported	NA
18h	30h	0000h		
19h	32h	0000h	Address for Alternate Algorithm extended Query table	NA
1Ah	34h	0000h		

Note: Query data are always presented on the lowest order data outputs (DQ7-DQ0) only. DQ8-DQ15 are '0'.

Table 23. CFI Query System Interface Information

Address		Data	Description	Value
x16	x8			
1Bh	36h	0027h	V _{CC} Logic Supply Minimum Program/Erase voltage bit 7 to 4 BCD value in volts bit 3 to 0 BCD value in 100 mV	2.7V
1Ch	38h	0036h	V _{CC} Logic Supply Maximum Program/Erase voltage bit 7 to 4 BCD value in volts bit 3 to 0 BCD value in 100 mV	3.6V
1Dh	3Ah	00B5h	V _{PP} [Programming] Supply Minimum Program/Erase voltage bit 7 to 4 HEX value in volts bit 3 to 0 BCD value in 100 mV	11.5V
1Eh	3Ch	00C5h	V _{PP} [Programming] Supply Maximum Program/Erase voltage bit 7 to 4 HEX value in volts bit 3 to 0 BCD value in 100 mV	12.5V
1Fh	3Eh	0004h	Typical timeout per single byte/word program = 2 ⁿ μs	16μs
20h	40h	0000h	Typical timeout for minimum size write buffer program = 2 ⁿ μs	NA
21h	42h	000Ah	Typical timeout per individual block erase = 2 ⁿ ms	1s
22h	44h	0000h	Typical timeout for full chip erase = 2 ⁿ ms	NA
23h	46h	0004h	Maximum timeout for byte/word program = 2 ⁿ times typical	256 μs
24h	48h	0000h	Maximum timeout for write buffer program = 2 ⁿ times typical	NA
25h	4Ah	0003h	Maximum timeout per individual block erase = 2 ⁿ times typical	8s
26h	4Ch	0000h	Maximum timeout for chip erase = 2 ⁿ times typical	NA

Table 24. Device Geometry Definition

Address		Data	Description	Value
x16	x8			
27h	4Eh	0017h	Device Size = 2^n in number of bytes	8 MByte
28h 29h	50h 52h	0002h 0000h	Flash Device Interface Code description	x8, x16 Async.
2Ah 2Bh	54h 56h	0000h 0000h	Maximum number of bytes in multi-byte program or page = 2^n	NA
2Ch	58h	0002h	Number of Erase Block Regions. It specifies the number of regions containing contiguous Erase Blocks of the same size.	2
2Dh 2Eh	5Ah 5Ch	0007h 0000h	Region 1 Information Number of identical size erase block = 0007h+1	8
2Fh 30h	5Eh 60h	0020h 0000h	Region 1 Information Block size in Region 1 = 0020h * 256 byte	8Kbyte
31h 32h	62h 64h	007Eh 0000h	Region 2 Information Number of identical size erase block = 007Eh+1	127
33h 34h	66h 68h	0000h 0001h	Region 2 Information Block size in Region 2 = 0100h * 256 byte	64Kbyte

Note: The region information contained in addresses 2Dh to 34h (or 5Ah to 68h) is correct for the M29W640DB. For the M29W640DT the regions must be reversed.

Table 25. Primary Algorithm-Specific Extended Query Table

Address		Data	Description	Value
x16	x8			
40h	80h	0050h	Primary Algorithm extended Query table unique ASCII string "PRI"	"P"

62h	C5h, C4h	XXXX	
63h	C7h, C6h	XXXX	
64h	C9h, C8h	XXXX	

APPENDIX C. EXTENDED MEMORY BLOCK

The M29W640D has an extra block, the Extended Block, that can be accessed using a dedicated command.

This Extended Block is 32 KWords in x16 mode and 64 KBytes in x8 mode. It is used as a security block (to provide a permanent security identification number) or to store additional information.

The Extended Block is either Factory Locked or Customer Lockable, its status is indicated by bit DQ7. This bit is permanently set to either '1' or '0' at the factory and cannot be changed. When set to '1', it indicates that the device is factory locked and the Extended Block is protected. When set to '0', it indicates that the device is customer lockable and the Extended Block is unprotected. Bit DQ7 being permanently locked to either '1' or '0' is another security feature which ensures that a customer lockable device cannot be used instead of a factory locked one.

Bit DQ7 is the most significant bit in the Extended Block Verify Code and a specific procedure must be followed to read it. See "Extended Memory Block Verify Code" in Tables 2 and 3, Bus Operations, BYTE = V_{IL} and Bus Operations, BYTE = V_{IH} , respectively, for details of how to read bit DQ7.

The Extended Block can only be accessed when the device is in Extended Block mode. For details of how the Extended Block mode is entered and exited, refer to the Enter Extended Block Command and Exit Extended Block Command paragraphs, and to Tables 4 and 5, "Commands, 16-bit mode, BYTE = V_{IH} " and "Commands, 8-bit mode, BYTE = V_{IL} ", respectively.

Factory Locked Extended Block

In devices where the Extended Block is factory locked, the Security Identification Number is written to the Extended Block address space (see Table 27, Extended Block Address and Data) in the factory. The DQ7 bit is set to '1' and the Extended Block cannot be unprotected.

Customer Lockable Extended Block

A device where the Extended Block is customer lockable is delivered with the DQ7 bit set to '0' and the Extended Block unprotected. It is up to the customer to program and protect the Extended Block but care must be taken because the protection of the Extended Block is not reversible.

There are two ways of protecting the Extended Block:

- Issue the Enter Extended Block command to place the device in Extended Block mode, then use the In-System Technique (refer to Appendix D, In-System Technique and to the corresponding flowcharts, Figures 18 and 19, for a detailed explanation of the technique).
- Issue the Enter Extended Block command to place the device in Extended Block mode, then use the Programmer Technique (refer to Appendix D, Programmer Technique and to the corresponding flowcharts, Figures 16 and 17, for a detailed explanation of the technique).

Once the Extended Block is programmed and protected, the Exit Extended Block command must be issued to exit the Extended Block mode and return the device to Read mode.

Table 27. Extended Block Address and Data

Device	Address ⁽¹⁾		Data	
	x8	x16	Factory Locked	Customer Lockable
M29W640DT	7F0000h-7F000Fh	3F8000h-3F8007h	Security Identification Number	Determined by Customer
	7F0010h-7FFFFFFh	3F8008h-3FFFFFFh	Unavailable	
M29W640DB	000000h-00000Fh	000000h-000007h	Security Identification Number	Determined by Customer
	000010h-00FFFFFFh	000008h-007FFFh	Unavailable	

Note: 1. See Tables 19 and 20, Top and Bottom Boot Block Addresses.

APPENDIX D. BLOCK PROTECTION

Block protection can be used to prevent any operation from modifying the data stored in the memory. The blocks are protected in groups, refer to Appendix A, Table 19 and Table 20 for details of the Protection Groups. Once protected, Program and Erase operations within the protected group fail to change the data.

There are three techniques that can be used to control Block Protection, these are the Programmer technique, the In-System technique and Temporary Unprotection. Temporary Unprotection is controlled by the Reset/Block Temporary Unprotection pin, RP; this is described in the Signal Descriptions section.

Programmer Technique

The Programmer technique uses high (V_{ID}) voltage levels on some of the bus pins. These cannot be achieved using a standard microprocessor bus, therefore the technique is recommended only for use in Programming Equipment.

To protect a group of blocks follow the flowchart in Figure 16, Programmer Equipment Group Protect Flowchart. To unprotect the whole chip it is necessary to protect all of the groups first, then all groups can be unprotected at the same time. To unprotect the chip follow Figure 17, Programmer Equipment Chip Unprotect Flowchart. Table 28, Programmer Technique Bus Operations, BYTE = V_{IH} or V_{IL} , gives a summary of each operation.

The timing on these flowcharts is critical. Care should be taken to ensure that, where a pause is specified, it is followed as closely as possible. Do not abort the procedure before reaching the end. Chip Unprotect can take several seconds and a user message should be provided to show that the operation is progressing.

In-System Technique

The In-System technique requires a high voltage level on the Reset/Blocks Temporary Unprotect pin, RP. This can be achieved without violating the maximum ratings of the components on the microprocessor bus, therefore this technique is suitable for use after the memory has been fitted to the system.

To protect a group of blocks follow the flowchart in Figure 18, In-System Equipment Group Protect Flowchart. To unprotect the whole chip it is necessary to protect all of the groups first, then all the groups can be unprotected at the same time. To unprotect the chip follow Figure 19, In-System Equipment Chip Unprotect Flowchart.

The timing on these flowcharts is critical. Care should be taken to ensure that, where a pause is specified, it is followed as closely as possible. Do not allow the microprocessor to service interrupts that will upset the timing and do not abort the procedure before reaching the end. Chip Unprotect can take several seconds and a user message should be provided to show that the operation is progressing.

Table 28. Programmer Technique Bus Operations, $\overline{\text{BYTE}} = V_{IH}$ or V_{IL}

Operation	\overline{E}	\overline{G}	\overline{W}	Address Inputs A0-A21	Data Inputs/Outputs DQ15A-1, DQ14-DQ0
Block (Group) Protect ⁽¹⁾	V_{IL}	V_{ID}	V_{IL} Pulse	A9 = V_{ID} , A12-A21 Block Address Others = X	X
Chip Unprotect	V_{ID}	V_{ID}	V_{IL} Pulse	A9 = V_{ID} , A12 = V_{IH} , A15 = V_{IH} Others = X	X
Block (Group) Protection Verify	V_{IL}	V_{IL}	V_{IH}	A0 = V_{IL} , A1 = V_{IH} , A6 = V_{IL} , A9 = V_{ID} , A12-A21 Block Address Others = X	Pass = XX01h Retry = XX00h
Block (Group) Unprotection Verify	V_{IL}	V_{IL}	V_{IH}	A0 = V_{IL} , A1 = V_{IH} , A6 = V_{IH} , A9 = V_{ID} , A12-A21 Block Address Others = X	Retry = XX01h Pass = XX00h

REVISION HISTORY

Table 29. Document Revision History

Date	Version	Revision Details
14-Dec-2001	-01	Document released
19-Apr-2002	-02	Description of Ready/Busy signal clarified (and Figure 12 modified) Clarified allowable commands during block erase Clarified the mode the device returns to in the CFI Read Query command section tPLYH (time to reset device) respecified. Correction to table of Commands.
24-Apr-2002	-03	Values for addresses 23h and 25h corrected in CFI Query System Interface Information table in Appendix B
05-Sep-2002	3.1	When in Extended Block mode, the block at the boot block address can be used as OTP. Value of electronic signature changed. Data Toggle Flow chart corrected. SO44 package removed. Double Word Program Time (typ) changed to 20s. Revision numbering modified: a minor revision will be indicated by incrementing the digit after the dot, and a major revision, by incrementing the digit before the dot (revision version 03 equals 3.0).
08-Jan-2003	3.2	Values corrected for typical times for Double Word Program (Byte or Word) and Chip Program (Quadruple Byte, Double Word) in the Program, Erase Times and Program, Erase Endurance Cycles table. Document promoted from Product Preview to Preliminary Data.
04-Apr-2003	3.3	Data Retention and Erase Suspend Latency Time parameters added to Table 6, Program, Erase Times and Program, Erase Endurance Cycles, and Typical after 100k W/E Cycles column removed. I _{ID} (Identification) current removed from Table 11, DC Characteristics. Data modified at addresses 2Eh, 31h, 32h in Table 24. Extended Memory Block Verify Codes modified in Tables 2 and 3, "Bus Operations, BYTE = V _{IL} " and "Bus Operations, BYTE = V _{IH} ", respectively. Block 75 address space corrected for x8 mode in Table 19, Top Boot Block Addresses, M29W640DT, and Block 71 address space corrected for x8 mode in Table 20, Bottom Boot Block Addresses, M29W640DB. Appendix C, EXTENDED MEMORY BLOCK, added. V _{SS} pin connection to ground clarified. Lead-free package options E and F added to Table 18, Ordering Information Scheme.
