# 3V Dual 8-Bit, 20/40/60MSPS A/D Converter with Internal Voltage Reference

The ISL5640 is a monolithic, dual 8-bit analog-to-digital converter fabricated in an advanced CMOS process. It is designed for high speed applications where integration, bandwidth and accuracy are essential. The ISL5640 features a 9-stage pipeline architecture. The fully pipelined architecture and an innovative input stage enable the ISL5640 to accept a variety of input configurations, single-ended or fully differential. Only one external clock is necessary to drive both converters and an internal band-gap voltage reference is provided. This allows the system designer to realize an increased level of system integration resulting in decreased cost and power dissipation.

The ISL5640 has excellent dynamic performance while consuming less than 100mW power at 40MSPS. The A/D only requires a single +3.0V power supply. Data output latches are provided which present valid data to the output bus with a latency of 5 clock cycles.

The ISL5640 is offered in 20MSPS, 30MSPS, 40MSPS and 60MSPS sampling rates.

#### NOTE:

# **Detailed Description**

# Theory of Operation

The ISL5640 is a dual 8-bit fully differential sampling pipeline A/D converter with digital error correction logic. Figure 3 depicts the circuit for the front end differential-in-differentialout sample-and-hold (S/H) amplifiers. The switches are controlled by an internal sampling clock which is a nonoverlapping two phase signal,  $\Phi_1$  and  $\Phi_2$ , derived from the master sampling clock. During the sampling phase,  $\Phi_1$ , the input signal is applied to the sampling capacitors, CS. At the same time the holding capacitors, CH, are discharged to analog ground. At the falling edge of  $\Phi_1$  the input signal is sampled on the bottom plates of the sampling capacitors. In the next clock phase,  $\Phi_2$ , the two bottom plates of the sampling capacitors are connected together and the holding capacitors are switched to the op amp output nodes. The charge then redistributes between C<sub>S</sub> and C<sub>H</sub> completing one sample-and-hold cycle. The front end sample-and-hold output is a fully-differential, sampled-data representation of the analog input. The circuit not only performs the sample-andhold function but will also convert a single-ended input to a fully-differential output for the converter core. During the sampling phase, the I/Q<sub>IN</sub> pins see only the on-resistance of a switch and C<sub>S</sub>. The relatively small values of these components result in a typical full power input bandwidth of 400MHz for the converter.

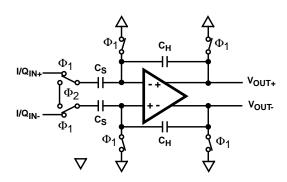

FIGURE 3. ANALOG INPUT SAMPLE-AND-HOLD

As illustrated in the Functional Block Diagram and the timing diagram in Figure 1, eight identical pipeline subconverter stages, each containing a two-bit flash converter and a two-bit multiplying digital-to-analog converter, follow the S/H circuit with the ninth stage being a two bit flash converter. Each converter stage in the pipeline will be sampling in one phase and amplifying in the other clock phase. Each individual subconverter clock signal is offset by 180 degrees from the previous stage clock signal resulting in alternate stages in the pipeline performing the same operation.

The output of each of the eight identical two-bit subconverter stages is a two-bit digital word containing a supplementary bit to be used by the digital error correction logic. The output of each subconverter stage is input to a digital delay line which is controlled by the internal sampling clock. The function of the digital delay line is to time align the digital outputs of the eight identical two-bit subconverter stages with the corresponding output of the ninth stage flash converter before applying the eighteen bit result to the digital error correction logic. The digital error correction logic uses the supplementary bits to correct any error that may exist before generating the final ten bit digital data output of the converter.

Because of the pipeline nature of this converter, the digital data representing an analog input sample is output to the digital data bus following the 6th cycle of the clock after the

<sup>7.</sup> The voltages listed above represent the ideal center of each output code shown with V<sub>REFIN</sub> = +1.25V.

analog sample is taken (see the timing diagram in Figure 1). This time delay is specified as the data latency. After the data latency time, the digital data representing each succeeding analog sample is output during the following clock cycle. The digital output data is provided in offset binary format (see Table 1, A/D Code Table).

### Internal Reference Voltage Output, VROUT

The ISL5640 is equipped with an internal 1.25V bandgap reference voltage generator, therefore, no external reference voltage is required.  $V_{ROUT}$  should be connected to  $V_{RIN}$  when using the internal reference voltage. An external, user-supplied,  $0.1\mu F$  capacitor may be connected from the  $V_{ROUT}$  output pin to filter any stray board noise.

# Reference Voltage Inputs, I/Q V<sub>REFIN</sub>

The ISL5640 is designed to accept a 1.25V reference voltage source at the  $V_{R\,IN}$  input pins for the I and Q channels. Typical operation of the converter requires  $V_{R\,IN}$  to be set at 1.25V. The ISL5640 is tested with  $V_{R\,IN}$  connected to  $V_{R\,OUT}$  yielding a fully differential analog input voltage range of  $\pm 0.5$ V.

The user does have the option of supplying an external 1.25V reference voltage. As a result of the high input impedance presented at the  $V_{RIN}$  input pin,  $M\Omega$  typically, the external reference voltage being used is only required to source small amount of reference input current.

In order to minimize overall converter noise it is recommended that adequate high frequency decoupling be provided at the reference voltage input pin, V<sub>RIN</sub>.

### Analog Input, Differential Connection

The analog input of the ISL5640 is a differential input that can be configured in various ways depending on the signal source and the required level of performance. A fully differential connection (Figure 4 and Figure 5) will deliver the best performance from the converter.

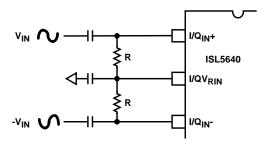

FIGURE 4. AC COUPLED DIFFERENTIAL INPUT

Since the ISL5640 is powered by a single +3V analog supply, the analog input is limited to be between ground and +3V. For the differential input connection this implies the analog input common mode voltage can range from 0.25V to 2.75V. The performance of the ADC does not change significantly with the value of the analog input common mode voltage.

For the AC coupled differential input (Figure 4) and with  $V_{RIN}$  connected to  $V_{ROUT}$ , full scale is achieved when the  $V_{IN}$  and  $-V_{IN}$  input signals are  $0.5V_{P-P}$ , with  $-V_{IN}$  being 180 degrees out of phase with  $V_{IN}$ . The converter will be at positive full scale when the  $I/Q_{IN}$ + input is at  $I/Q_{VRIN}$  + 0.25V and the  $I/Q_{IN}$ - input is at  $I/Q_{VRIN}$  - 0.25V ( $I/Q_{IN}$ + -  $I/Q_{IN}$ - = +0.5V). Conversely, the converter will be at negative full scale when the  $I/Q_{IN}$ + input is equal to  $I/Q_{VRIN}$  - 0.25V and  $I/Q_{IN}$ - is at  $I/Q_{VRIN}$  + 0.25V ( $I/Q_{IN}$ + -  $I/Q_{IN}$ - = -0.5V).

The analog input can be DC coupled (Figure 5) as long as the inputs are within the analog input common mode voltage range ( $0.25V \le VDC \le 2.75V$ ).

The resistors, R, in Figure 5 are not absolutely necessary but may be used as load setting resistors. A capacitor, C, connected from  $I/Q_{IN}+$  to  $I/Q_{IN}-$  will help filter any high frequency noise on the inputs, also improving performance. Values around 20pF are sufficient and can be used on AC coupled inputs as well. Note, however, that the value of capacitor C chosen must take into account the highest frequency component of the analog input signal.

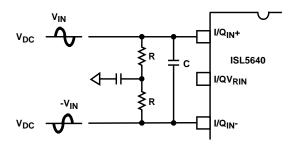

FIGURE 5. DC COUPLED DIFFERENTIAL INPUT

### Analog Input, Single-Ended Connection

The configuration shown in Figure 6 may be used with a single ended AC coupled input.

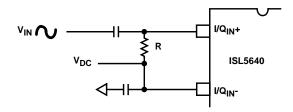

FIGURE 6. AC COUPLED SINGLE ENDED INPUT

Again, with V<sub>RIN</sub> connected to V<sub>ROUT</sub>, if V<sub>IN</sub> is a 1V<sub>P-P</sub> sinewave, then I/Q<sub>IN</sub>+ is a 1.0V<sub>P-P</sub> sinewave riding on a positive voltage equal to V<sub>DC</sub>. The converter will be at positive full scale when I/Q<sub>IN</sub>+ is at V<sub>DC</sub> + 0.5V (I/Q<sub>IN</sub>+ - I/Q<sub>IN</sub>- = +0.5V) and will be at negative full scale when I/Q<sub>IN</sub>+ is equal to V<sub>DC</sub> - 0.5V (I/Q<sub>IN</sub>+ - I/Q<sub>IN</sub>- = -0.5V). Sufficient

headroom must be provided such that the input voltage never goes above +3V or below AGND. In this case,  $V_{DC}$  could range between 0.5V and 2.5V without a significant change in ADC performance. The simplest way to produce VDC is to use the  $I/Q_{VRIN}$  bias source,  $I/QV_{DC}$ , output of the ISL5640.

The single ended analog input can be DC coupled (Figure 7) as long as the input is within the analog input common mode voltage range.

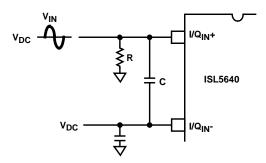

FIGURE 7. DC COUPLED SINGLE ENDED INPUT

The resistor, R, in Figure 7 is not absolutely necessary but may be used as a load setting resistor. A capacitor, C, connected from  $I/Q_{IN}+$  to  $I/Q_{IN}-$  will help filter any high frequency noise on the inputs, also improving performance. Values around 20pF are sufficient and can be used on AC coupled inputs as well. Note, however, that the value of capacitor C chosen must take into account the highest frequency component of the analog input signal.

A single ended source may give better overall system performance if it is first converted to differential before driving the ISL5640.

#### **Operational Mode**

The ISL5640 contains several operational modes including a normal two channel operation, placing one or both channels in standby and delaying the Q channel data 1/2 clock cycle. The operational mode is selected via the S1 and S2 pins and is asynchronous to either clock. When either channel is placed in standby, the output data is stalled and not high impedance. When recovering from standby, valid data is available after 20 clock cycles.

The delay mode can be used to set the Q channel 180 degrees out phase of the I channel if the same clock is driving both channels. If separate, inverted clocks are used for the I and Q channels, this feature can be used to align the data.

#### **OPERATIONAL MODES**

S1	S2	MODE
0	0	Standby I and Q Channels.
0	1	I channel operates normally with Q Channel in standby mode.
1	0	I and Q Channels operating with I/Q output data in phase.
1	1	I and Q Channels operating with Q data 180 degrees out of phase.

## Sampling Clock Requirements

The ISL5640 sampling clock input provides a standard highspeed interface to external TTL/CMOS logic families.

In order to ensure rated performance of the ISL5640, the duty cycle of the clock should be held at 50% ±5%. It must also have low jitter and operate at standard TTL/CMOS levels.

Performance of the ISL5640 will only be guaranteed at conversion rates above 1MSPS (Typ). This ensures proper performance of the internal dynamic circuits. Similarly, when power is first applied to the converter, a maximum of 20 cycles at a sample rate above 1MSPS must be performed before valid data is available.

## Supply and Ground Considerations

The ISL5640 has separate analog and digital supply and ground pins to keep digital noise out of the analog signal path. The part should be mounted on a board that provides separate low impedance connections for the analog and digital supplies and grounds. For best performance, the supplies to the ISL5640 should be driven by clean, linear regulated supplies. The board should also have good high frequency decoupling capacitors mounted as close as possible to the converter. If the part is powered off a single supply then the analog supply can be isolated by a ferrite bead from the digital supply.
