### DESCRIPTION

The M74HC221A is an high speed CMOS MONOSTABLE MULTIVIBRATOR fabricated with silicon gate C<sup>2</sup>MOS technology.

There are two trigger inputs, A INPUT (negative edge) and B INPUT (positive edge).

Triggering on the B input occurs at a particular voltage threshold and is not related to rise and fall time of the applied pulse. The device may also be trigger by using the CLR input (positive edge) because of the Schmitt-trigger input; after

triggering the output maintains the MONOSTABLE STATE for the time period determined by the external resistor Rx and capacitor Cx. Taking CLR low breaks this MONOSTABLE STATE. If the next trigger pulse occurs during the MONOSTABLE period it makes the MONOSTABLE period longer.

Limit for values of Cx and Rx :

Cx : NO LIMIT

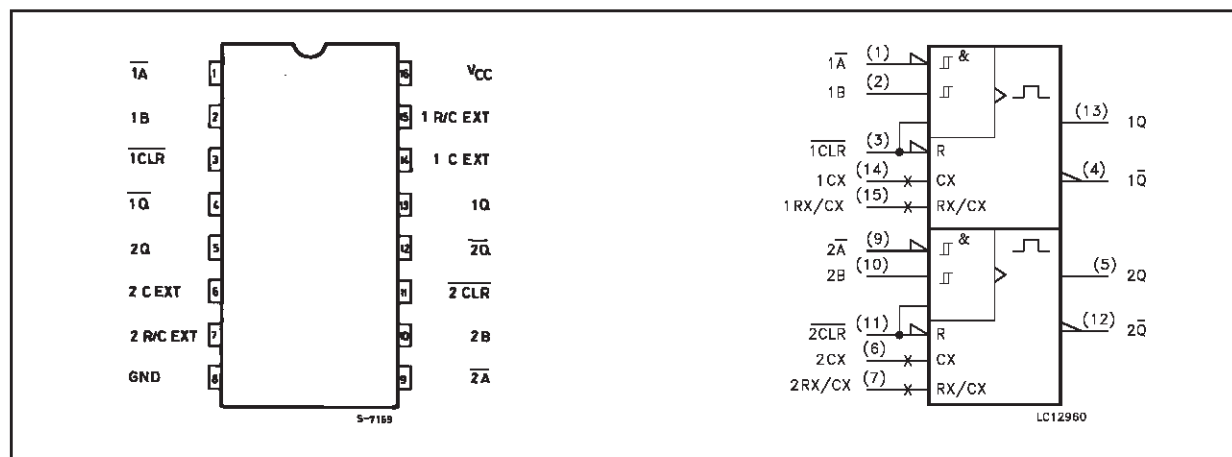

Rx :  $V_{CC} < 3.0V$  5KΩ to 1MΩ

$V_{CC} \geq 3.0V$  1KΩ to 1MΩ

K ≅ 1

All inputs are equipped with protection circuits against static discharge and transient excess voltage.

## SYSTEM DIAGRAM

## TIMING CHART

## BLOCK DIAGRAM

(1) Cx, Rx, Dx are external components.

(2) Dx is a clamping diode.

The external capacitor is charged to Vcc in the stand-by-state, i.e. no trigger. When the supply voltage is turned off Cx is discharged mainly through an internal parasitic diode (see figures). If Cx is sufficiently large and Vcc decreases rapidly, there will be some possibility of damaging the I.C. with a surge current or latch-up. If the voltage supply filter capacitor is large enough and Vcc decreases slowly, the surge current is automatically limited and damage to the I.C. is avoided. The maximum forward current of the parasitic diode is approximately 20 mA. In cases where Cx is large the time taken for the supply voltage to fall to 0.4 Vcc can be calculated as follows:

$$t_f \geq (V_{cc} - 0.7) \times Cx / 20\text{mA}$$

In cases where  $t_f$  is too short an external clamping diode is required to protect the I.C. from the surge current.

## FUNCTIONAL DESCRIPTION

## STAND-BY STATE

The external capacitor, Cx, is fully charged to Vcc in the stand-by state. Hence, before triggering, transistor Qp and Qn (connected to the Rx/Cx node) are both turned-off. The two comparators that control the timing and the two reference voltage sources stop operating. The total supply current is therefore only leakage current.

## TRIGGER OPERATION

Triggering occurs when:

- 1 st) A is "LOW" and B has a falling edge;
- 2 nd) B is "HIGH" and A has a rising edge;
- 3 rd) A is "LOW" and B is HIGH and C1 has a rising edge;

After the multivibrator has been retriggered comparator C1 and C2 start operating and Qn is turned on. Cx then discharges through Qn. The voltage at the node R/C external falls.

When it reaches  $V_{REFL}$  the output of comparator C1 becomes low. This in turn resets the flip-flop and Qn is turned off.

At this point C1 stops functioning but C2 continues to operate.

The voltage at R/C external begins to rise with a time constant set by the external components Rx, Cx.

Triggering the multivibrator causes Q to go high after internal delay due to the flip-flop and the gate. Q remains high until the voltage at R/C external rises again to  $V_{REFH}$ . At this point C2 output goes low and O goes low. C2 stops operating. That means that after triggering when the voltage R/C external returns to  $V_{REFH}$  the multivibrator has returned to its MONOSTABLE STATE. In the case where Rx · Cx are large enough and the discharge time of the capacitor and the delay time in the I.C. can be ignored, the width of the output pulse  $t_w$  (out) is as follows:

$$t_w(\text{OUT}) = Cx \cdot Rx$$

## RESET OPERATION

CL is normally high. If CL is low, the trigger is not effective because Q output goes low and trigger control flip-flop is reset.

Also transistor Op is turned on and Cx is charged quickly to Vcc. This means if CL input goes low the IC becomes waiting state both in operating and non operating state.
