

SPI CONTROLLED H-BRIDGE

PRELIMINARY DATA

- OPERATING SUPPLY VOLTAGE 5V TO 28V
- TYPICAL $R_{DS(on)} = 150 \text{ m}\Omega$ FOR EACH OUTPUT TRANSISTOR (AT 25°C)
- CONTINUOUS DC LOAD CURRENT 5A ($T_{case} < 100 \text{ }^\circ\text{C}$)
- OUTPUT CURRENT LIMITATION AT TYP. 6A
- SHORT CIRCUIT SHUT DOWN FOR OUTPUT CURRENTS OVER 8A
- LOGIC- INPUTS TTL/CMOS-COMPATIBLE
- OPERATING-FREQUENCY UP TO 30 kHz
- OVER TEMPERATURE PROTECTION
- SHORT CIRCUIT PROTECTION
- UNDERVOLTAGE DISABLE FUNCTION
- DIAGNOSTIC BY SPI OR STATUS-FLAG (CONFIGURABLE)
- ENABLE AND DISABLE INPUT
- SO20 POWER PACKAGE

DESCRIPTION

The L9230 is an SPI controlled H-Bridge, designed for the control of DC and stepper motors in safety critical applications and under extreme environmental conditions.

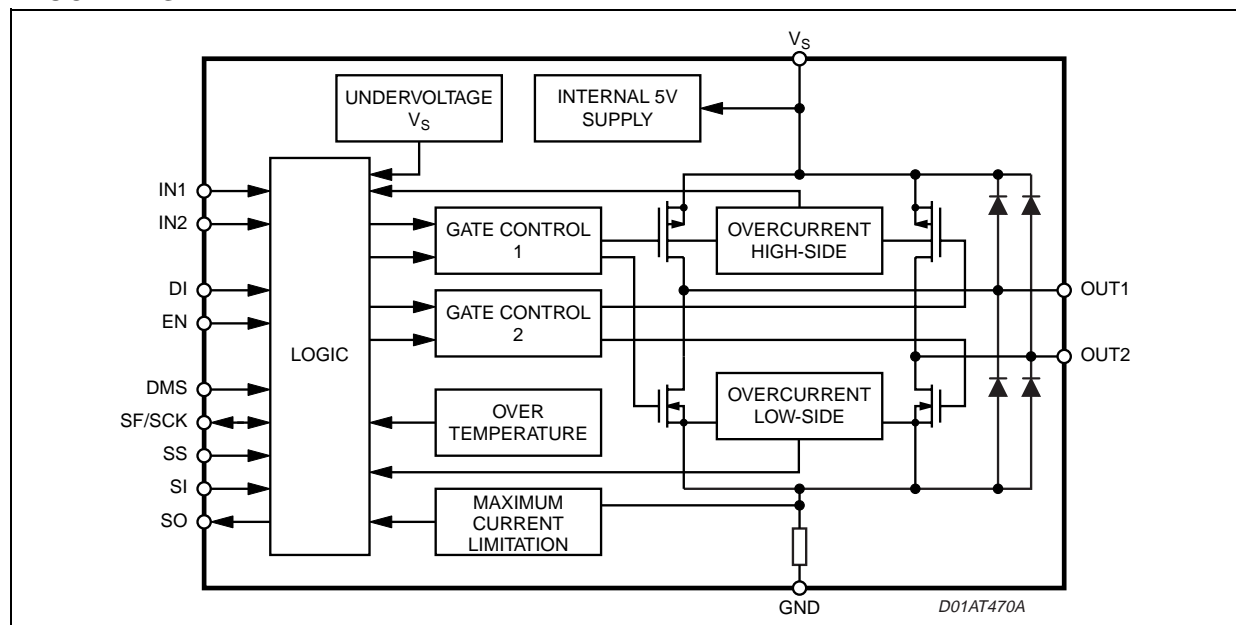

The H-Bridge is protected against over temperature and short circuits and has an under voltage lockout for all the supply voltages "V_S" (Main DC power supply). All malfunctions cause the output stages to go tristate.

The H-Bridge contains integrated free-wheel diodes. In case of free-wheeling condition, the lowside transistor is switched on in parallel of its diode to reduce the current injected into the substrate.

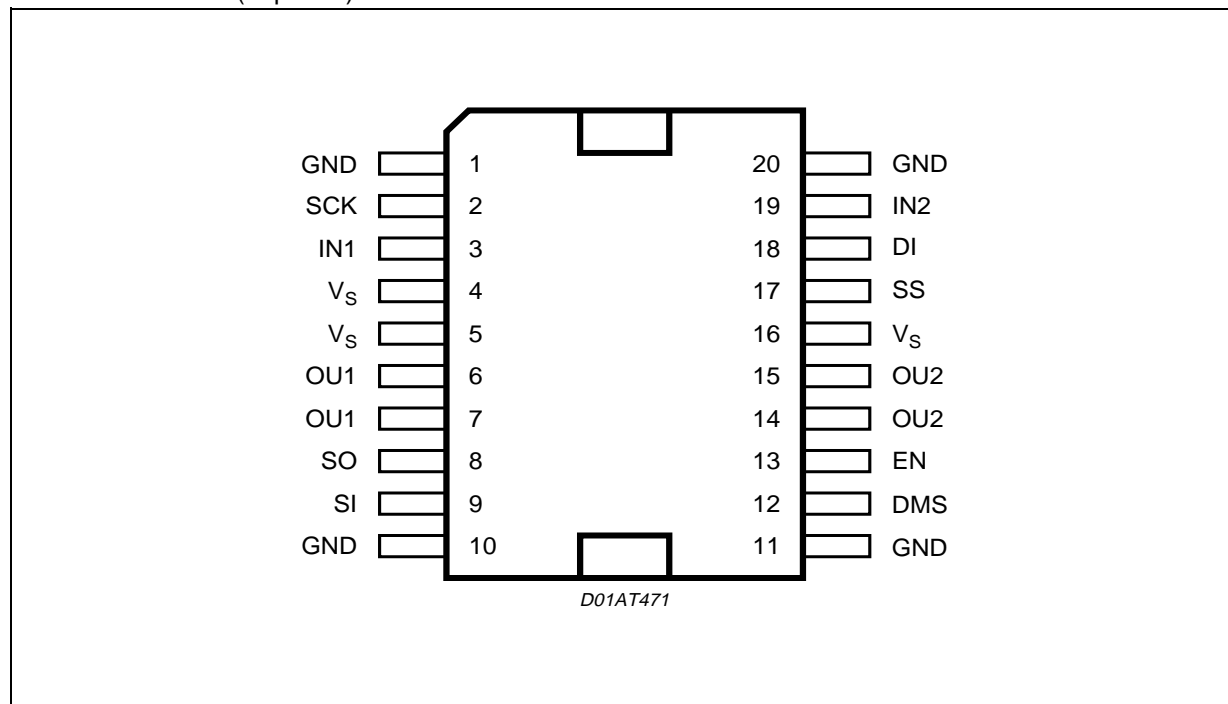

Switching in parallel is only allowed, if the voltage-level of the according output-stage is below the ground-level. In this case it must be ensured, that the upper transistor is switched off.

PIN CONNECTION (Top view)

ABSOLUTE MAXIMUM RATINGS

The integrated circuit must not be destroyed by use at the limit values.

Each limit value can be used, as long as no other limit is violated.

Voltage reference point: All values are, if not otherwise stated, relative to ground.

Direction of current flow: Current flow into a pin is positive.

Rise-, fall- and delaytimes: If not otherwise stated, all rise times are between 10% and 90%, fall times between 90% and 10% and delay times at 50% of the relevant steps.

Symbol	Parameter	Test Condition	Min.	Typ.	Max.	Unit
V _S	Supply voltage	static destruction proof	-1		40	V
		dynamic destruction proof t < 0.5s (single pulse, T _j < 85°C)	-2		40	V
V _{LI}	Logic inputs IN1, IN2, DI, EN, SS, SI, SCK,DMS		-0.5		7	V
I _{LI}	Logic inputs IN1, IN2, DI, EN, SS, SI, SCK,DMS				-20	mA
V _{LO}	Logic outputs SF, SO	R ≥ 10kΩ	-0.5		7	V

THERMAL DATA

Symbol	Parameter	Test Condition	Min.	Typ.	Max.	Unit
T _j	Junction temperature		-40		+150	°C
		dynamic t < 1 s			+175	°C
T _{stg}	Storage temperature		-55		+125	°C
T _{amb}	Ambient temperature		-40		+125	°C
R _{th j-case}	Thermal resistance junction to case ⁽²⁾				3	°C/W
T _{j_s}	Thermal Shutdown Junction Temperature Threshold		165	175		°C

ELECTRICAL CHARACTERISTICS (T_j = -40 to +150°C; V_S = 5 to 28V)

Symbol	Parameter	Test Condition	Min.	Typ.	Max.	Unit
Power Supply						
V _S	Supply Voltage	Static Condition	5		28	V
		Dynamic Condition (t < 500ms)			40	V
	Undervoltage Shutdown	(at least down to 2.5V) ⁽¹⁾		4.7	5	V
	Switch OFF voltage			4.5	5	V
	Switch ON voltage			4.7	5	V

For $165^{\circ}\text{C} < T_j < 175^{\circ}\text{C}$ the maximum current decreases fromfor $< 1s$ 175°C $> 175^{\circ}\text{C}$ $6,6A \pm 1,1A$ $T_j < 165^{\circ}\text{C}$ $I_{max.} = 6,6A \pm 1,1A$ to $I_{max.} = 2,5A \pm 1,1A$.

ELECTRICAL CHARACTERISTICS (continued)**SPI INTERFACE**

The timing of L9230 is defined as follows:

- The change at output (SO) is forced by the rising edge of the SCK signal.
- The input signal (SI) is taken over on the falling edge of the SCK signal.
- \overline{SS} = active without any clocks at SCK is not allowed
- The data received during a writing access is taken over into the internal registers on the rising edge of the \overline{SS} signal, if exactly 16 SPI clocks have been counted during \overline{SS} = active.

- 1.) In case of undervoltage tristate and status-flag are reset automatically.
- 2.) Whenever overcurrent or overtemperature is detected, the fault is stored (i.e. status-flag remains low). The tristate conditions and the status-flag ³⁾ are reset via DI or EN.

L = Low

H = High

X = High or Low

Z = High impedance

(all output stage transistors are switched off in static state. For more inform. see next page)

Overcurrent: $I_{OUT1,2} > 8,0 \text{ A}$

Overtemperature: $T_j > 175^\circ\text{C}$

Undervoltage: $V_{VS-GND} < 5.0 \text{ V}$ (at least down to 2,5V)

- 3.) If Mode „Status-Flag“ is selected (see 1.5)
- 4.) If Mode „SPI-Diagnosis is selected (see 1.5)

Description of the state „Z“

The state „Z“ has, depending on the previous operating condition different meaning.

1. dynamical

I. e. the inductive load is current carrying and is switched off according to Pos. 5, 6, 9, 10, 11, 12, 13, or 14 of the truth table

- a.) All output stage transistors are switched off.
- b.) The current flow is continued via the free wheeling diodes.
- c.) Free wheeling is detected by a negative voltage-level at OUn.
- d.) Switch on of the parallel-transistor of the current carrying diode.
- f.) Free wheeling is finished, if the voltage-level on OUn is positive again.

2. statical

- g.) all output-stages switched off.

Figure 7.

DIAGNOSTIC

The Diagnosis-Mode can be selected between SPI-Diagnosis and Status-Flag Diagnosis.

The choice of the Diagnosis-Mode is selected by the voltage-level on pin 12 (DMS Diagnosis Mode Selection).

DMS = GND Status-Flag

DMS = Vcc SPI-Diagnostic

For the connection of pins SI, SO, SS and SCK/SF see Fig. 10 respectively Fig. 11.

Status-Flag

The Status-Flag shows the condition „tristate“.

At the following fault-cases the output-stages switches in tristate and set the status-flag from high to low.

- Short circuit of OUT1 or OUT2 against V_S or GND
- Short circuit between OUT1 and OUT2
- Overcurrent
- Overtemperature
- Undervoltage on V_S

In cause of short circuit or overcurrent, the fault will be stored.

The output stage switches in tristate and the status-flag is set from high level to low-level if the specified value is exceeded.

If the voltage level changes from high to low on DI or from low to high on EN, the output stage switches on again and the status-flag is reset to high-level.

In cause of overtemperature the fault will be stored.

The output stage switches in tristate and the status-flag is set from high level to low-level if the specified value is exceeded.

the voltage level changes from high to low on DI or from low to high on EN, the output stage switches on again and the status-flag is reset to high-level.

In cause of undervoltage on V_{Batt} the output stage switches in tristate and the status-flag is set from high level to low-level if the specified value is fallen. If the voltage has risen about the specified value again, the output stage switches on again and the status-flag is reset to high-level.

The maximum current which can flow under normal operating conditions is limited to typical $I_{max.} = 6,6A$.

When the maximum current value is reached, the output stages are switched tristate for a fixed time.

According to the time-constant the current decreases exponentially until the next switch-on occurs.

At the end if the fixed time the output stage switches on again and the status-flag is reset to high-level.

SPI-INTERFACE

General Discription

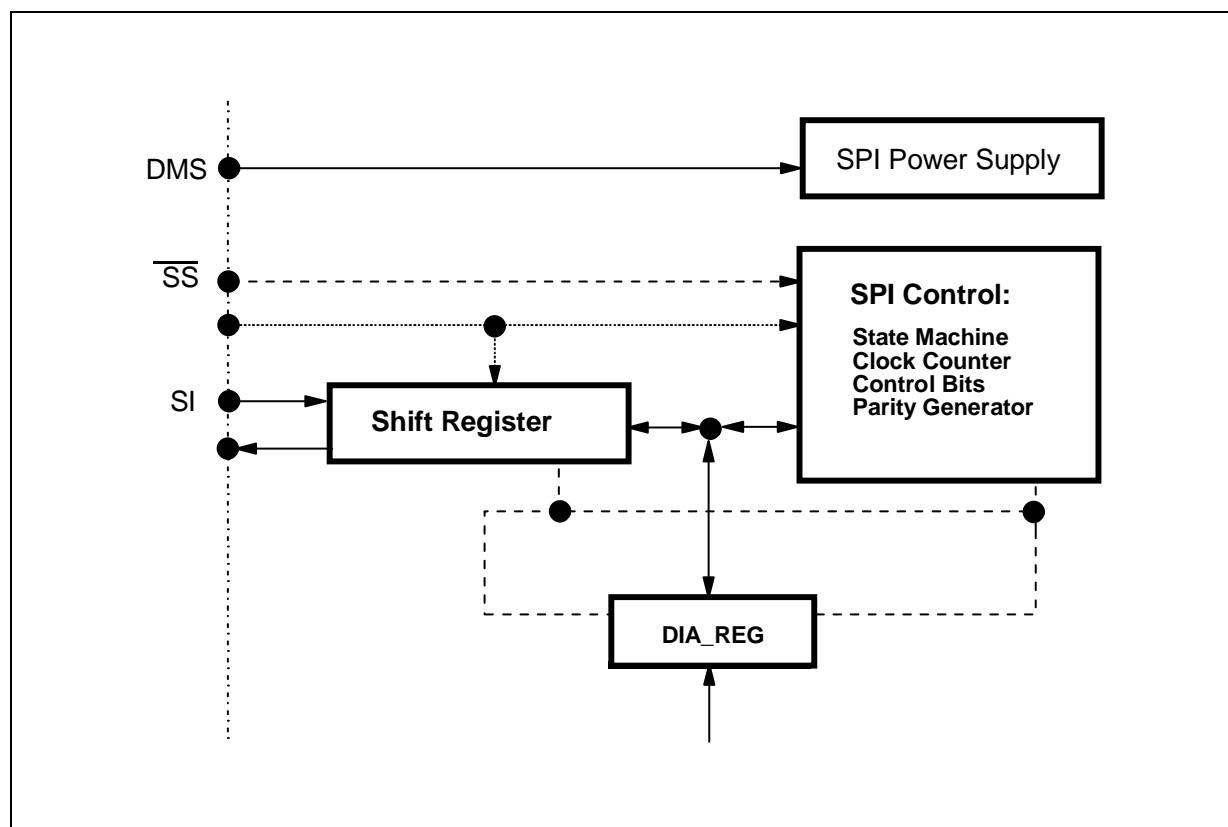

The serial SPI interface establishes a communication link between L9230 and the systems microcontroller. L9230 always operates in slave mode whereas the controller provides the master function.

The maximum baud rate is 2 MBaud (200pF).

Applying an active slave select signal at \overline{SS} L9230 is selected by the SPI master. SI is the data input (Slave In), SO the data output (Slave Out). Via SCK (Serial Clock Input) the SPI clock is provided by the master.

In case of inactive slave select signal (High) the data output SO goes into tristate.

Figure 8.

Depending on the application the first two bits of an instruction may be used to establish an extended device-addressing. This gives the opportunity to operate up to 4 Slave-devices sharing one common SS signal from the Master-Unit

Power Supply of the SPI-Interface

SPI-Logic and I/O-Pins are alternativ supplied from DMS or Vcc internal, depending on which voltage is higher. That is why diagnosis of the EN-/DI-Pins is always possible, even in case of missing H-Bridge-power supply e.g. during „Vorlauf/Nauchlauf“.

Characteristics of the SPI Interface

- 1) When DMS is $> 3,5V$, the SPI is active, independent of the state of EN or DI and the voltage on V_S .
During active reset conditions ($DMS < 3,5V$) the SPI is driven into its default state.
When reset becomes inactive, the state machine enters into a waitstate for the next instruction.
- 2) If the slave select signal at \overline{SS} is inactive (high), the state machine is forced to enter the waitstate, i.e. the state machine waits for the following instruction.
- 3) During active (low) state of the select signal \overline{SS} the falling edge of the serial clock signal SCK will be used to latch the input data at SI. Output data at SO are driven with the rising edge of SCK. Further processing of the data according to the instruction (i.e. modification of internal registers) will be triggered by the rising edge of the \overline{SS} signal. (-> See Note)

3) Chipaddress:

In order to establish the option of extended addressing the uppermost two bits of the instruction-byte (i.e the first two SI-bits of a Frame) are reserved to send a chipaddress. To avoid a busconflict the output SO must stay high impedant during the addressing phase of a frame (i.e. until the addressbits are recognised as valid chipaddress). This tristate behavior should be realised in any case, regardless whether the extended addressoption is used or not.

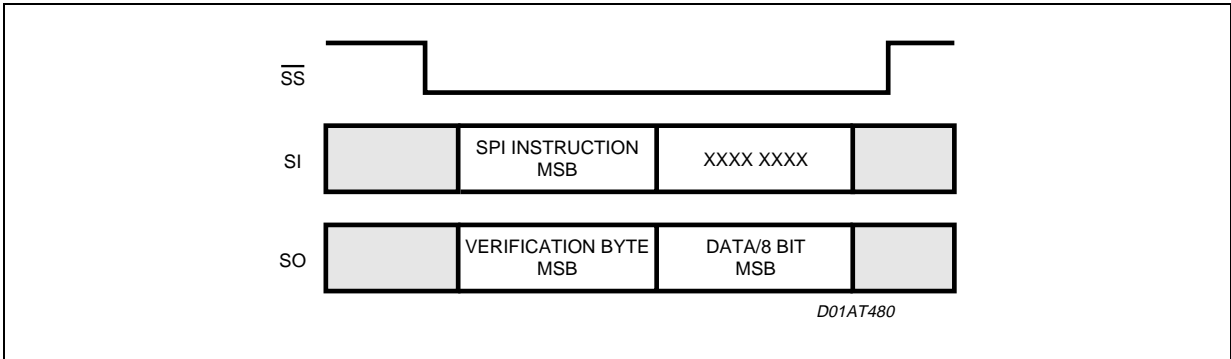

If the chipaddress does not match, the according access will be ignored and SO remains high impedant for the complete frame regardless which frametype is applied.

- 5) Check byte:
Simultaneously to the receipt of an SPI instruction L9230 transmits a check byte via the output SO to the controller. This byte indicates regular or irregular operation of the SPI. It contains an initial bitpattern and a flag indicating an invalid instruction of the previous access.
- 6) On the read access the databits at the SPI input SI are rejected.
- 7) Invalid instruction/access:
An instruction is invalid, if one of the following conditions is fulfilled:
 - an unused instruction code is detected (see tables with SPI instructions).
 - in case the previous transmission is not completed in terms of internal data processing.
(Violation of the minimum Access-Time.)
 If an invalid instruction is detected, any modifications on registers of L9230 are not allowed. In case an unused instruction code occurred the databyte "ff_{hex}" will be transmitted after having sent the check byte.

In addition any access is invalid if the number of SPI clock pulses (falling edge) counted during active \overline{SS} differs from exactly 16 clock pulses (-> See Note).

SPI Communication

Figure 9. Reading access / 8 bit

SPI Instruction

The uppermost 2 bit of the instruction byte contains the chipaddress. The individual chipaddress is a mask-option and must be defined in accordance to the SPI-Members sharing on SS line.

SPI Instruction-Format

MSB							
7	6	5	4	3	2	1	0
0	0	INSTR4	INSTR3	INSTR2	INSTR1	INSR0	INSW

Bit	Name	Description
7,6	CPAD1,0	Chip Adress (has to be '0', '0')
5-1	INSTR (4-0)	SPI instruction (encoding)
0	INSW	Don't care

SPI Instruction-Bytes

SPI Instruction	Encoding			Description

RD_VERSION	00	00001	1	read version
RD_DIA	00	00100	1	read DIA_REG
		all others		no function

Reset of the Diagnostic Register DIA_REG

On the following conditions DIA_REG is reset:

- DI high
- EN low
- With the rising edge of the SS-signal after the SPI-Instruction RD_DIA.
- When the voltage on DMS exceeds the threshold for detecting SPI-Mode.
(after undervoltage condition)
- Undervoltage on V_S ($< 5,0V$) sets Bit 0 Bit 3 of DIA_REG to 0000.
- If UB rises over about the undervoltage level, the Bits of DIA_REG are restored
(when V_S internal or $DMS > 3,5V$)

Verification byte:

MSB

Device Identifier

The IC's identifier is used for production test purposes and features plug & play functionality depending on the systems software release. It is made up on a device-number and a revision number each one read-only accessible via standardised instructions.

The Device number is defines once to allow indentification of different IC-Types by software.

The Revision number may be utilised to distinguish different states of hardware. The contents is divided into an upper 4 bit field reserved to define revisions correspondending to specific software releases.

The lower 4 bit field is utilised to indentify the actual maskset.

Both (SWR and MSR) will start with 0000_b and are increased by 1 every time an according modification of the hardware is introduced.

Reading the IC Identifier (SPI Instruction: RD_IDENTITY):

IC Identifier1 (Device ID)							
7	6	5	4	3	2	1	0
ID7	ID6	ID5	ID4	ID3	ID2	ID1	ID0
Bit	Name		Description				
7...0	ID(7...0)		ID-No.: 10100001 L9230				

Reading the IC revision number (SPI Instruction: RD_VERSION):

IC's revision number							
7	6	5	4	3	2	1	0
SWR3	SWR2	SWR1	SWR0	MSR3	MSR2	MSR1	MSR0
Bit	Name		Description				
7...4	SWR(3...0)		Revision corresponding to Software release: 0Hex				
3...0	MSR(3...0)		Revision corresponding to Maskset: 0Hex				

Figure 10. Application example with SPI-Interface

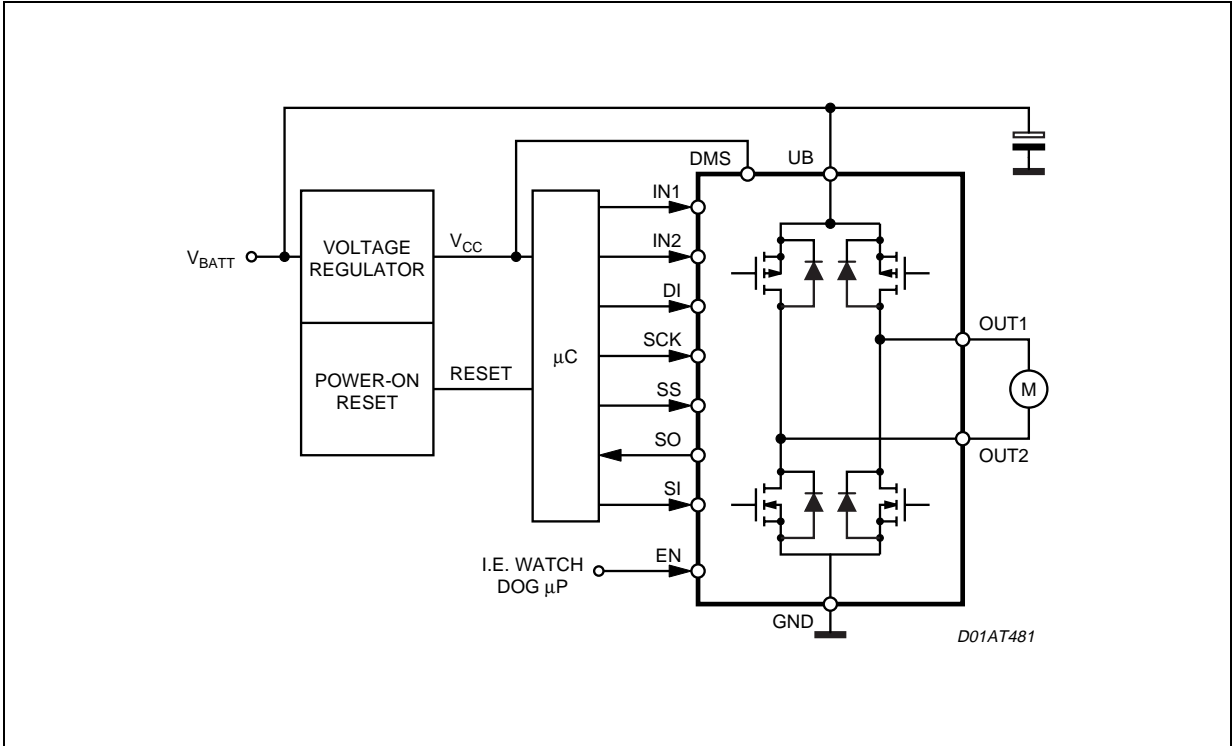

Figure 11. Application example with Status-Flag

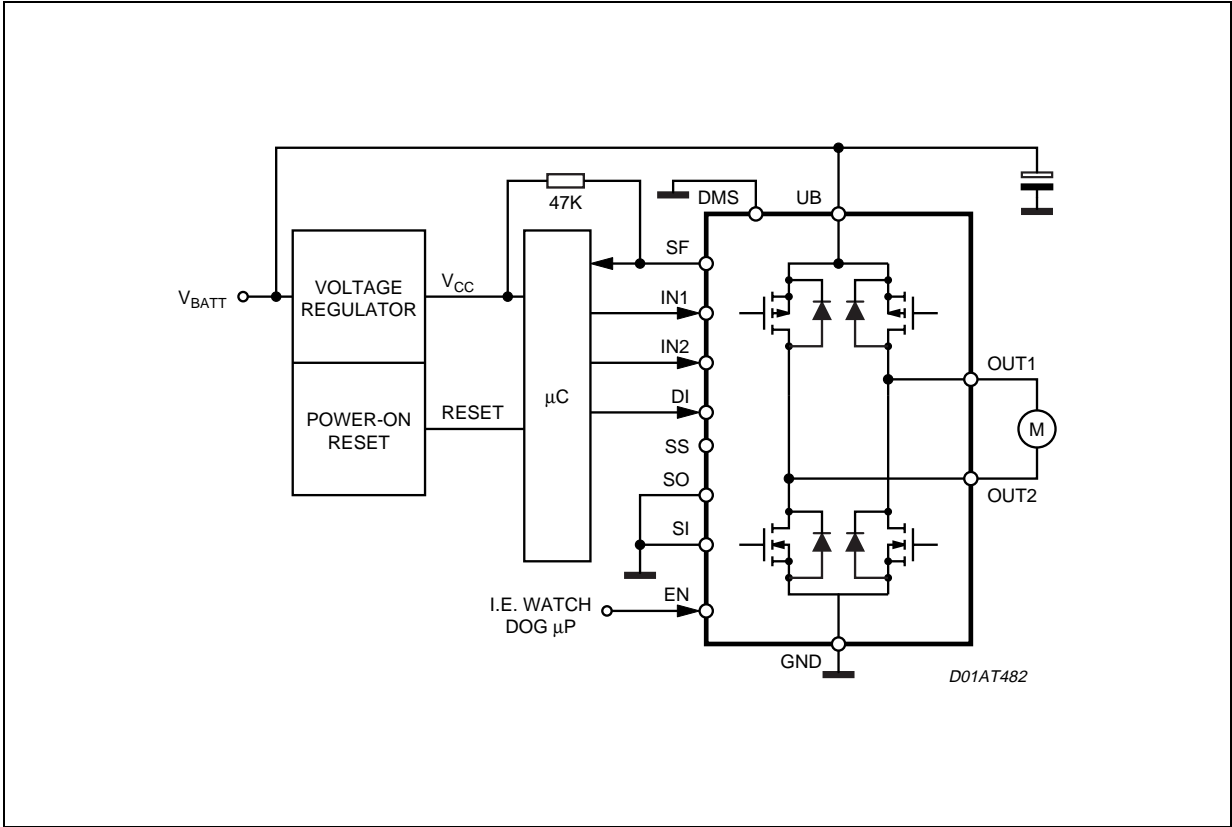

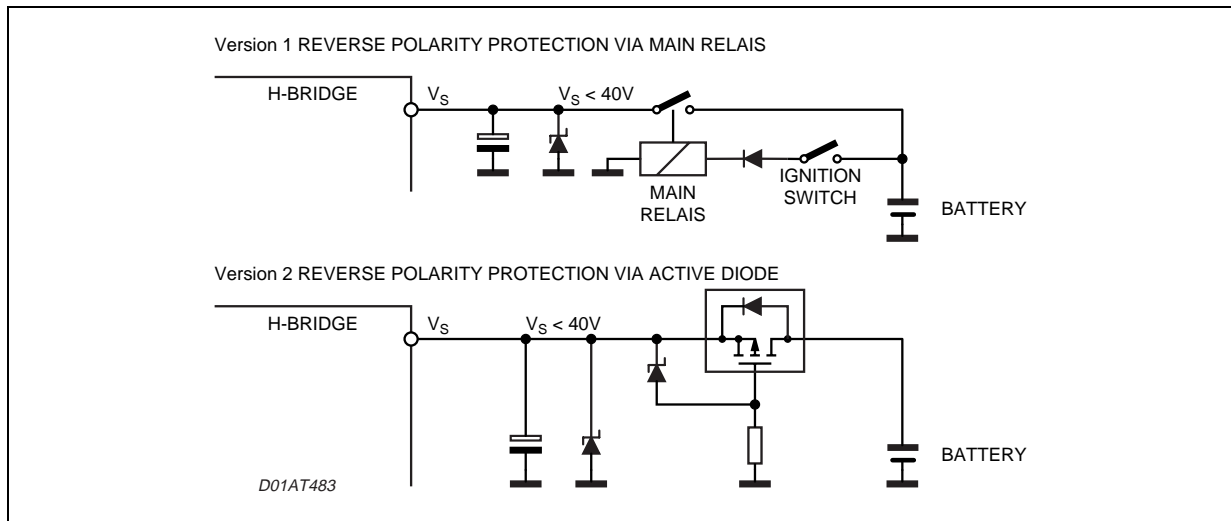

Figure 12. Application examples for Overvoltage- and Reverse-Voltage Protection

ESD-SOLIDITY

The connection pins of the IC have to be protected against Electrostatic Discharge ESD) by suitable integrated protection structures.

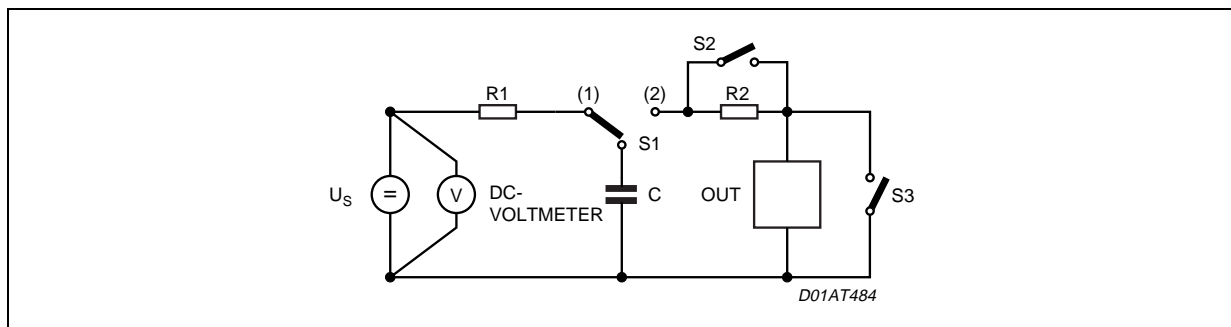

The integrated circuit has to meet the demand of the „Human-Body-Model“ with $V_C = \pm 4\text{kV}$
 $C = 100\text{pF}$ and $R_2 = 1,5\text{k}\Omega$ (330Ω for OUT1 and OUT2).

Thereby any defect or destruction of the integrated circuit must not occur.

The protection structures realized to reach the ESD-strength have to be coordinated.

The ESD-strength has to be verified by the test circuit given as below.

Figure 13.

For the Pins 4, 5, 6, 7, 14 and 15

$U_C = \pm 4\text{kV}$

$R_1 = 100\text{k}\Omega$

$R_2 = 330\Omega$

$C = 100\text{pF}$

Number of pulses each pin: 18

Frequency: 1Hz

Arrangement and performance:

The requirements of MIL883D Methode 3015 have to be fulfilled.

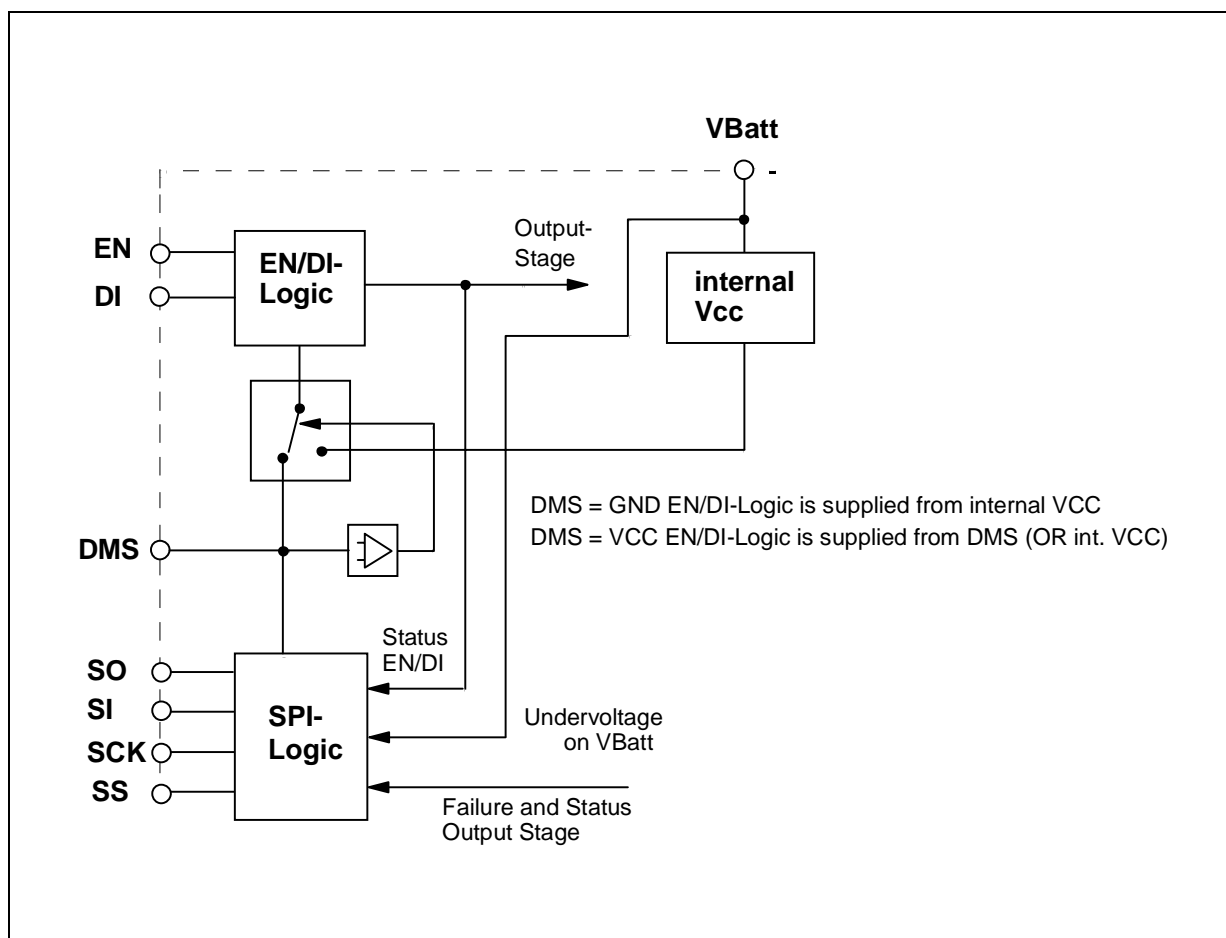

In the main-power-supply-system disturbance transients according to ISO 7637-1 First Edition 1990-06-01 may occur.

statical -1V +40V

dynamical for $t < 500$ ms -2V +40V
