

In-Circuit Serial Programming™ for PIC18CXXX OTP MCUs

This document includes the programming specifications for the following devices:

- PIC18C242
- PIC18C252
- PIC18C442
- PIC18C452
- PIC18C601
- PIC18C801
- PIC18C658
- PIC18C858

1.0 PROGRAMMING THE PIC18CXXX

The PIC18CXXX can be programmed using a serial method while in users' system, allowing increased design flexibility. This programming specification applies to PIC18CXXX devices in all package types.

1.1 Hardware Requirements

The PIC18CXXX requires two programmable power supplies, one for VDD and one for VPP. Both supplies should have a minimum resolution of 0.25V.

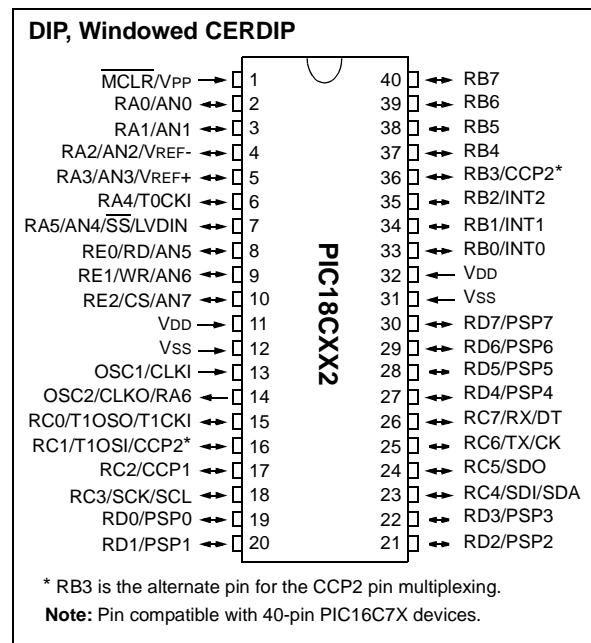

1.2 Programming Mode

The Programming mode for the PIC18CXXX allows programming of user program memory (except for the PIC18C601/801 ROMless devices), special locations used for ID, and the configuration words for the PIC18CXXX.

Pin Diagrams

The pin diagrams for the PIC18CXXX2 family are shown below in Figure 1-1 through Figure 1-3. Pin diagrams for the PIC18CXXX8 family are provided in Figure 1-4 through Figure 1-7. Pin diagrams for the PIC18C601/801 family are provided in Figure 1-8 through Figure 1-11.

2.0 IN-CIRCUIT SERIAL PROGRAMMING™ (ICSP™) MODE

2.1 Introduction

Serial Programming mode is entered by asserting $\overline{\text{MCLR}}/\text{VPP} = \text{VIHH}$ and $\text{RB6}, \text{RB7} = 0\text{V}$.

Instructions are fed into the CPU serially on RB7, and are shifted on the rising edge, and latched on the falling edge of the serial clock presented on RB6. RB7 serves as data out, as well. Programming and verification are performed by executing TBLRD and TBLWT instructions. The address pointer to the program memory is simply the table pointer. The address pointer can be incremented and decremented by executing table reads and writes with auto-decrement and auto-increment.

2.2 ICSP Operation

In ICSP mode, instruction execution takes place through a serial interface using RB6 and RB7. RB7 is used to shift in instructions and shift out data from the TABLAT register. RB6 is used as the serial shift clock and the CPU execution clock. Instructions and data are shifted LSb first.

In this mode, all instructions are shifted serially, loaded into the instruction register, and executed. No program fetching occurs from internal or external program memory. 8-bit data bytes are read from the TABLAT register via the same serial interface.

2.2.1 4-BIT SERIAL INSTRUCTIONS

A set of 4-bit instructions are provided for ICSP mode, so the most common instructions used for ICSP can be fetched quickly, and reduce the amount of time required to program a device. The 4-bit opcode is shifted in while the previously fetched instruction executes. The 4-bit instruction contains the lower 4 bits of an instruction opcode. The upper 12 bits default to all 0's. Instructions with all 0's in the upper byte of the instruction word are by default, considered special instructions. The serial instructions are decoded as shown in Table 2-1.

TABLE 2-1: SPECIAL INSTRUCTIONS FOR SERIAL INSTRUCTION EXECUTION AND ICSP

| Mnemonic, Operands | Description | Cycles | 4-bit Opcode | Status Affected |
|--------------------|--|--------|--------------|-----------------|
| NOP | No Operation (shift in 16-bit instruction) | 1 | 0000 | None |
| TBLRD * | Table Read (no change to TBLPTR) | 2 | 1000 | None |
| TBLRD *+ | Table Read (post-increment TBLPTR) | 2 | 1001 | None |
| TBLRD *- | Table Read (post-decrement TBLPTR) | 2 | 1010 | None |
| TBLRD +* | Table Read (pre-increment TBLPTR) | 2 | 1011 | None |
| TBLWT * | Table Write (no change to TBLPTR) | 2 | 1100 | None |
| TBLWT *+ | Table Write (post-increment TBLPTR) | 2 | 1101 | None |
| TBLWT *- | Table Write (post-decrement TBLPTR) | 2 | 1110 | None |
| TBLWT +* | Table Write (pre-increment TBLPTR) | 2 | 1111 | None |

Legend: Refer to the PIC18CXXX Data Sheet (DS39026 or DS30475) for opcode field descriptions.

Note: All special instructions not included in this table are decoded as NOPs.

2.2.2 INITIAL SERIAL INSTRUCTION OPERATION

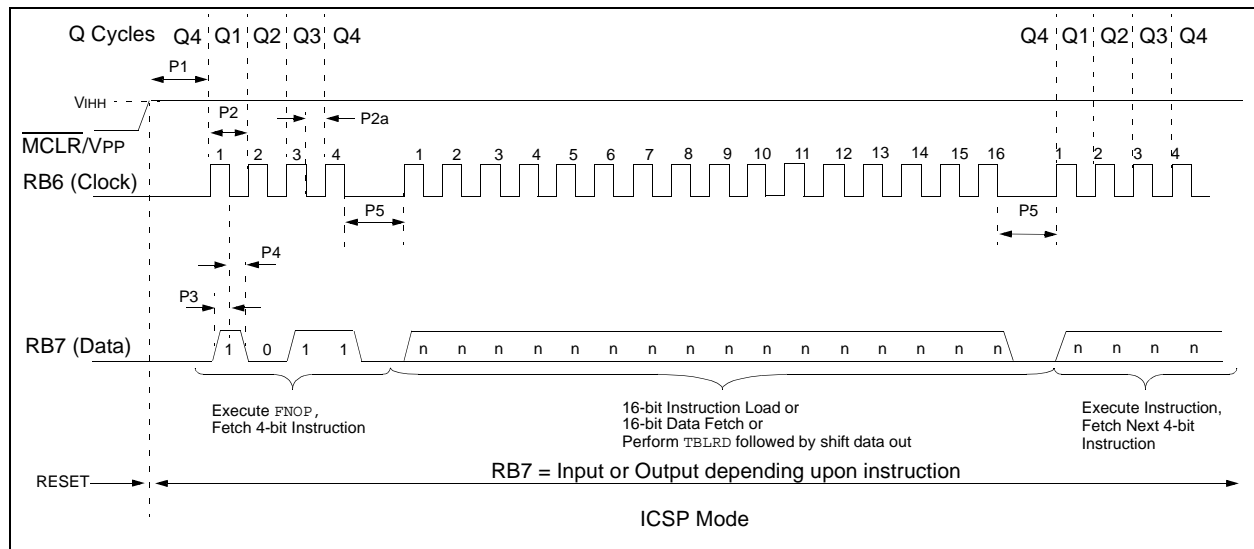

Upon ICSP mode entry, the CPU is idle. The execution of the CPU is governed by a state machine. While the first instruction is being clocked in, a forced NOP (FNOP) is executed.

Following the FNOP instruction execution and shifting in of the next instruction, the serial state machine will do one of three things, depending upon the 4-bit instruction fetched:

1. If the instruction fetched was a NOP, the state machine will suspend the CPU, awaiting a 16-bit wide instruction to be shifted in.
2. If the instruction is a TBLWT as shown in Figure 2-1, the state machine suspends the CPU from execution, while sixteen bits of data are shifted in as data for the TBLWT instruction.
3. If the instruction is a TBLRD, then execution of the TBLRD instruction begins immediately for eight clock cycles, followed by eight clock cycles where the contents of the TABLAT register is shifted out onto RB7.

Once sixteen clock cycles have elapsed, the next 4-bit instruction is fetched, while the current instruction is executed. Each instruction type is described in later sections.

FIGURE 2-1: SERIAL INSTRUCTION TIMING AFTER RESET

PIC18CXXX

2.2.3 NOP SERIAL INSTRUCTION EXECUTION

The NOP serial instruction is used to allow execution of all other instructions not included in Table 2-1. When the NOP instruction is fetched, the serial execution state machine suspends the CPU for 16 clock cycles. During these 16 clock cycles, all 16 bits of an instruction are fed into the CPU and the NOP instruction is discarded. Once all 16 bits have been shifted in, the state machine will allow the instruction to be executed for the next four clock cycles.

Note: 16-bit TBLWT and TBLRD instructions are not permitted. They will cause timing problems with the serial state machine. If the user wishes to perform a TBLWT or TBLRD instruction, it must be performed as a 4-bit instruction.

2.2.4 ONE-CYCLE 16-BIT INSTRUCTIONS

If the instruction fetched is a one-cycle instruction, then the instruction operation will be completed in the four clock cycles following the instruction fetched. During instruction execution, the next 4-bit serial instruction is fetched (see Figure 2-2).

FIGURE 2-2: SERIAL INSTRUCTION TIMING FOR 1-CYCLE, 16-BIT INSTRUCTIONS

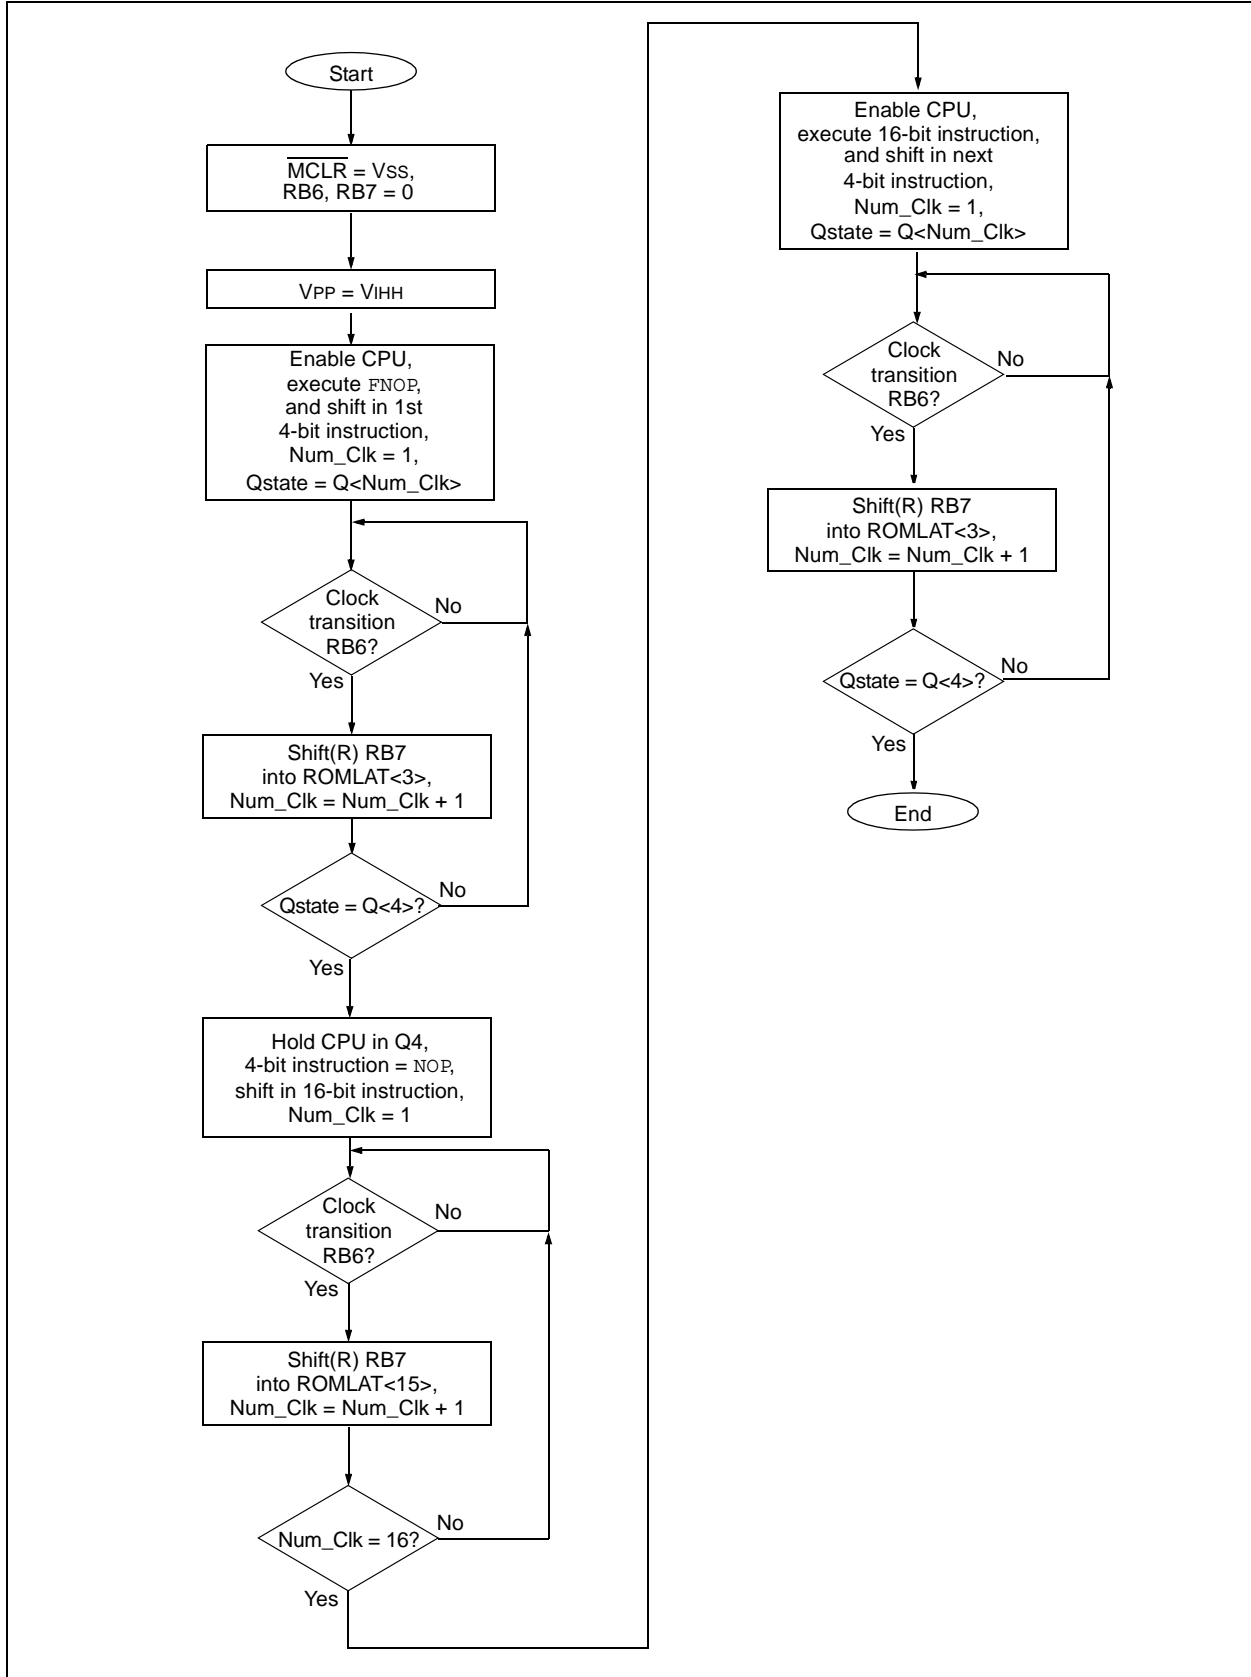

FIGURE 2-3: 16-BIT, 1-CYCLE SERIAL INSTRUCTION FLOW AFTER RESET

PIC18CXXX

FIGURE 2-4: 16-BIT, 1-CYCLE SERIAL INSTRUCTION FLOW

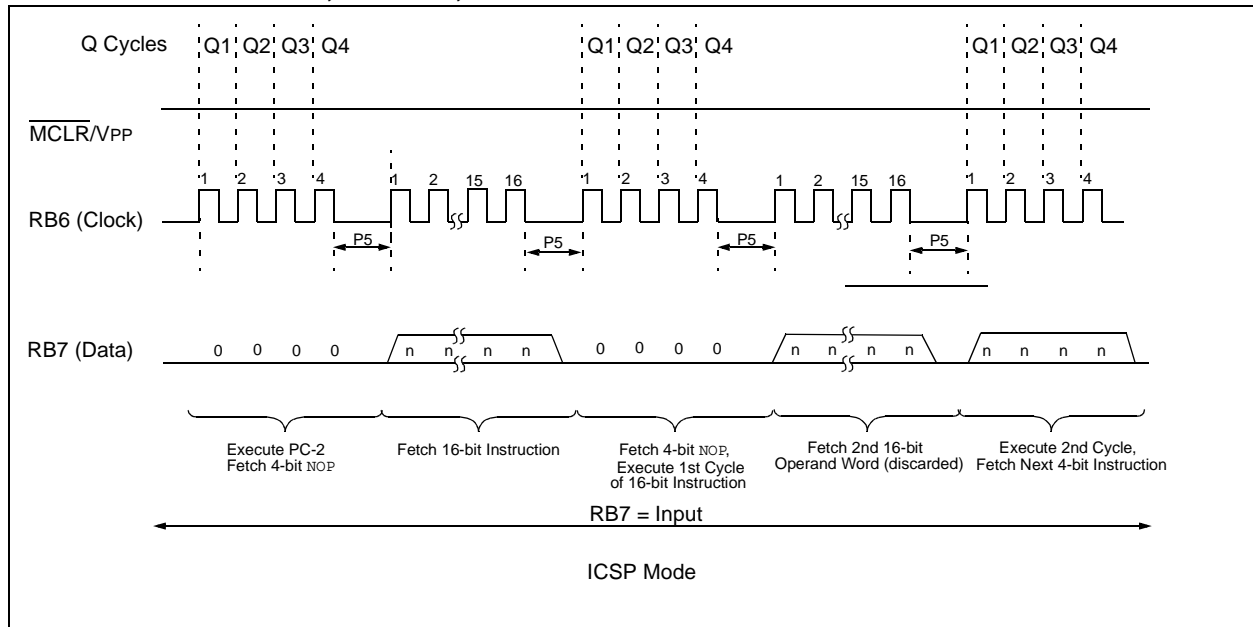

2.3 Serial Instruction Execution For Two-Cycle, One-Word Instructions

When a NOP instruction is fetched, the serial execution state machine suspends the CPU for 16 clock cycles. During these 16 clock cycles, all 16 bits of an instruction are fed in and the NOP instruction is discarded.

If the instruction fetched is a two-cycle, one-word instruction, the instruction operation will require a second “dummy fetch” to be performed before the instruction execution can be completed. The first cycle of the instruction will be executed in the four clock cycles following the instruction fetched. During the first cycle of instruction execution, the next 4-bit serial instruction is fetched. To perform the second half of the two cycle instruction, this 4-bit instruction must be a NOP, so the state machine will remain idle for the second half of the instruction. Following the fetch of the second NOP, the state machine will shift 16 bits of data that will be discarded. After the 16 bits of data are shifted in, the state machine will release the CPU, and allow it to perform the second half of the two-cycle instruction. During the second half of the two-cycle instruction execution, the next 4-bit instruction is loaded (see Figure 2-5).

FIGURE 2-5: 16-BIT, 2-CYCLE, 1-WORD INSTRUCTION SEQUENCE

PIC18CXXX

2.4 Serial Instruction Execution For Two-Word, Two-Cycle Instructions

After a NOP instruction is fetched, the serial execution state machine suspends the CPU in the Q4 state for 16 clock cycles. During these 16 clock cycles, all 16 bits of an instruction are fed in and the NOP instruction is discarded.

If the 16-bit instruction fetched is a two-cycle, two-word instruction, the instruction operation will require a second operand fetch to be performed before the instruction execution can be completed. The first cycle of the instruction will be executed in the four clock cycles following the 16-bit instruction fetch. During the first cycle of instruction execution, the next 4-bit serial instruction is fetched. To perform the second half of the two-cycle instruction, this 4-bit instruction must also be a NOP, so the state machine will remain idle for the second half of the instruction. Following the fetch of the second NOP, the state machine will shift 16 bits of data that will be used as an operand for the two-cycle instruction. After the 16 bits of data are shifted in, the state machine will release the CPU, and allow it to execute the second half of the two-cycle instruction. During the second half of the two-cycle instruction execution, the next 4-bit instruction is loaded (see Figure 2-6).

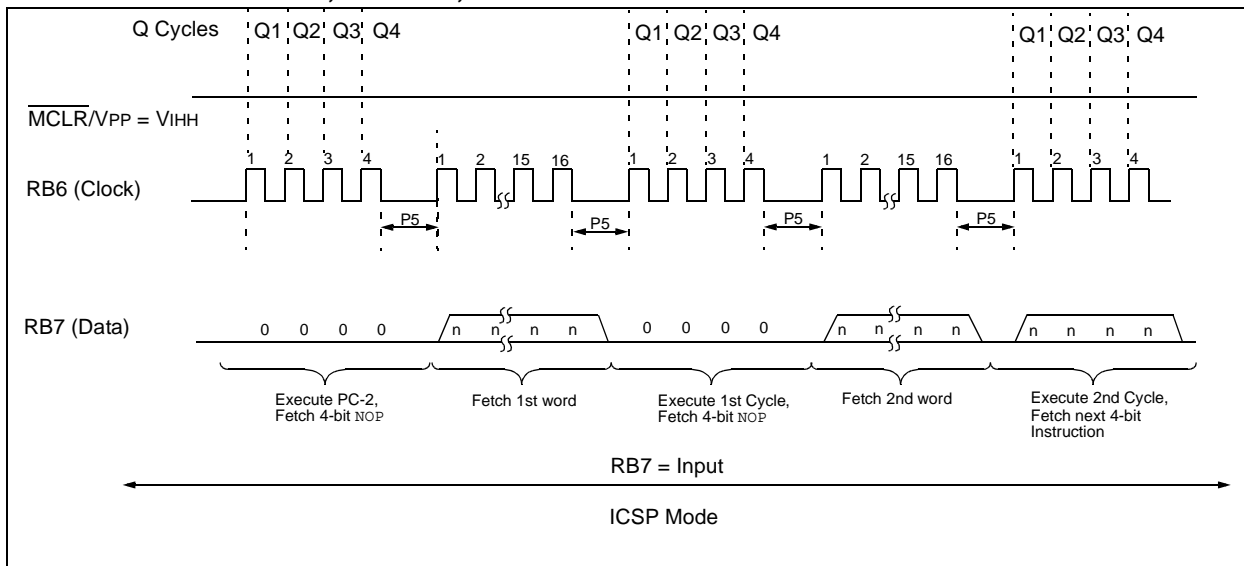

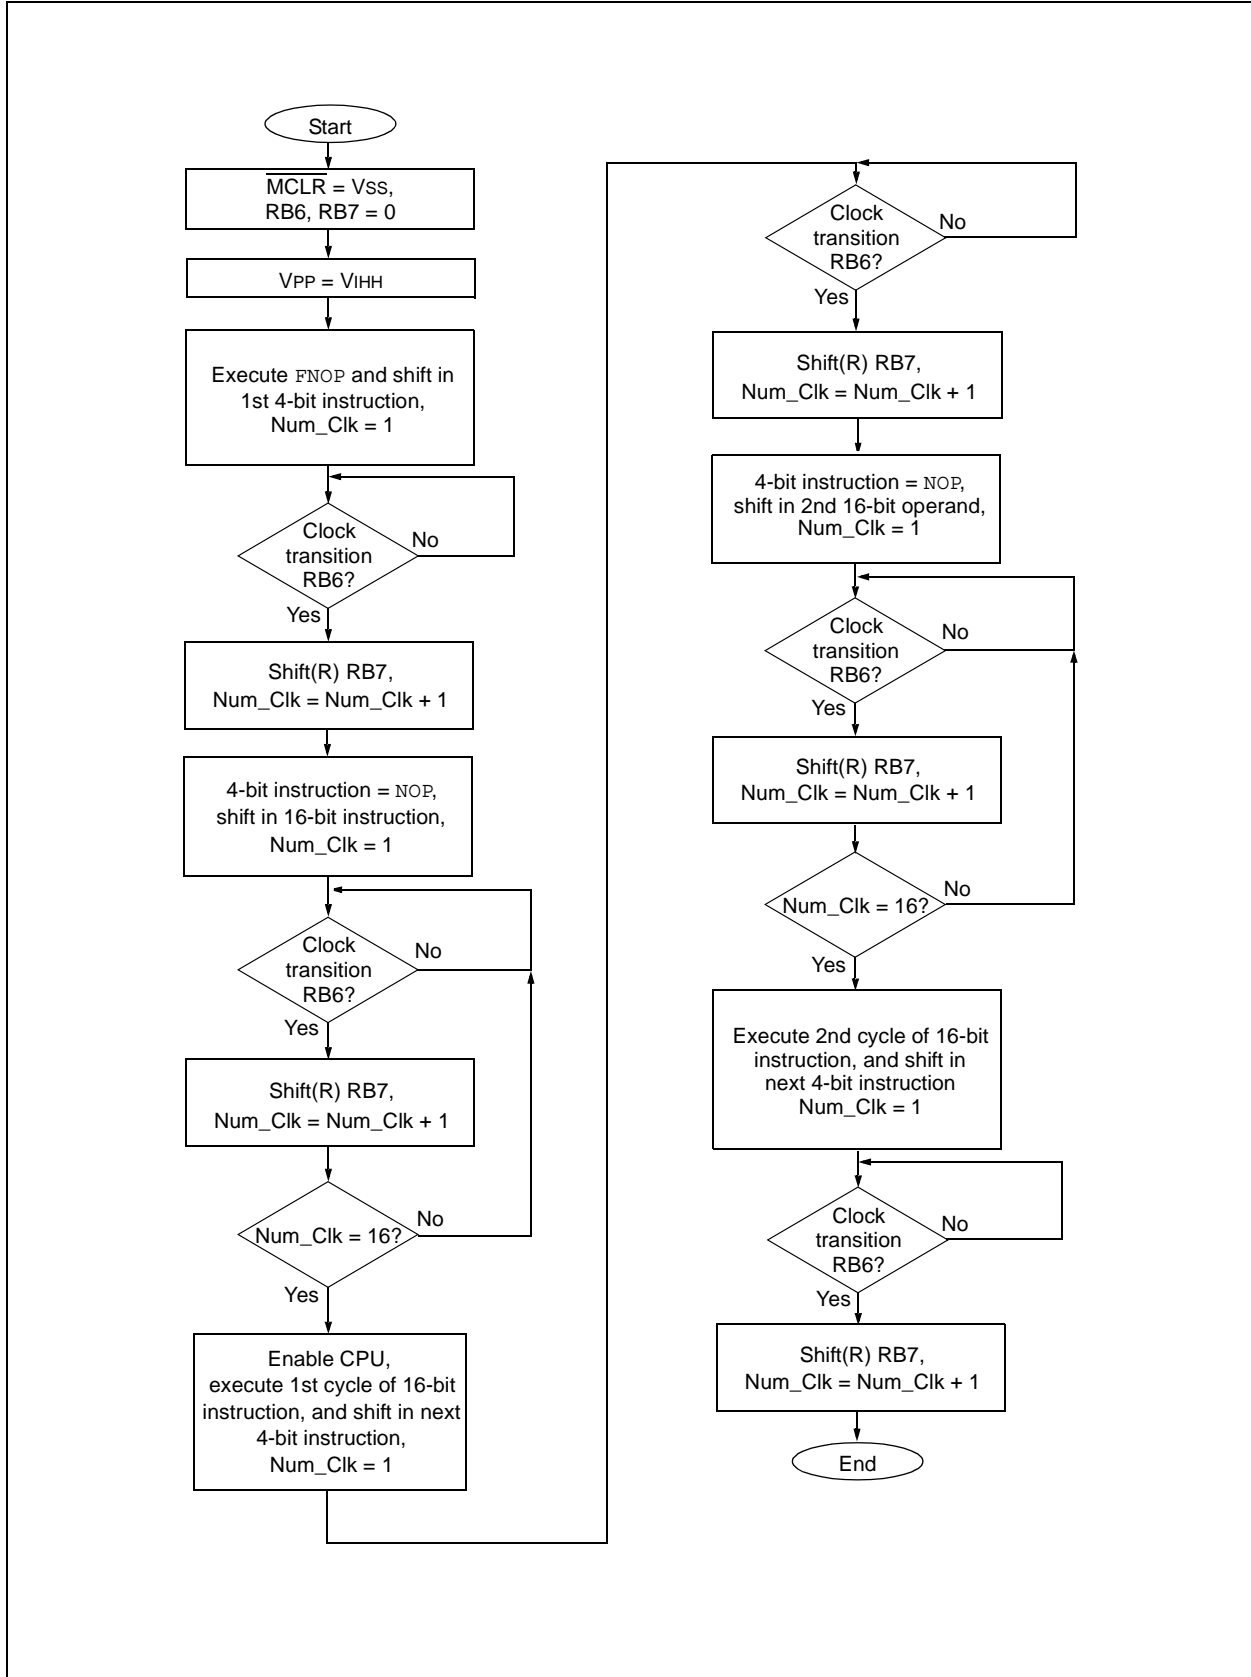

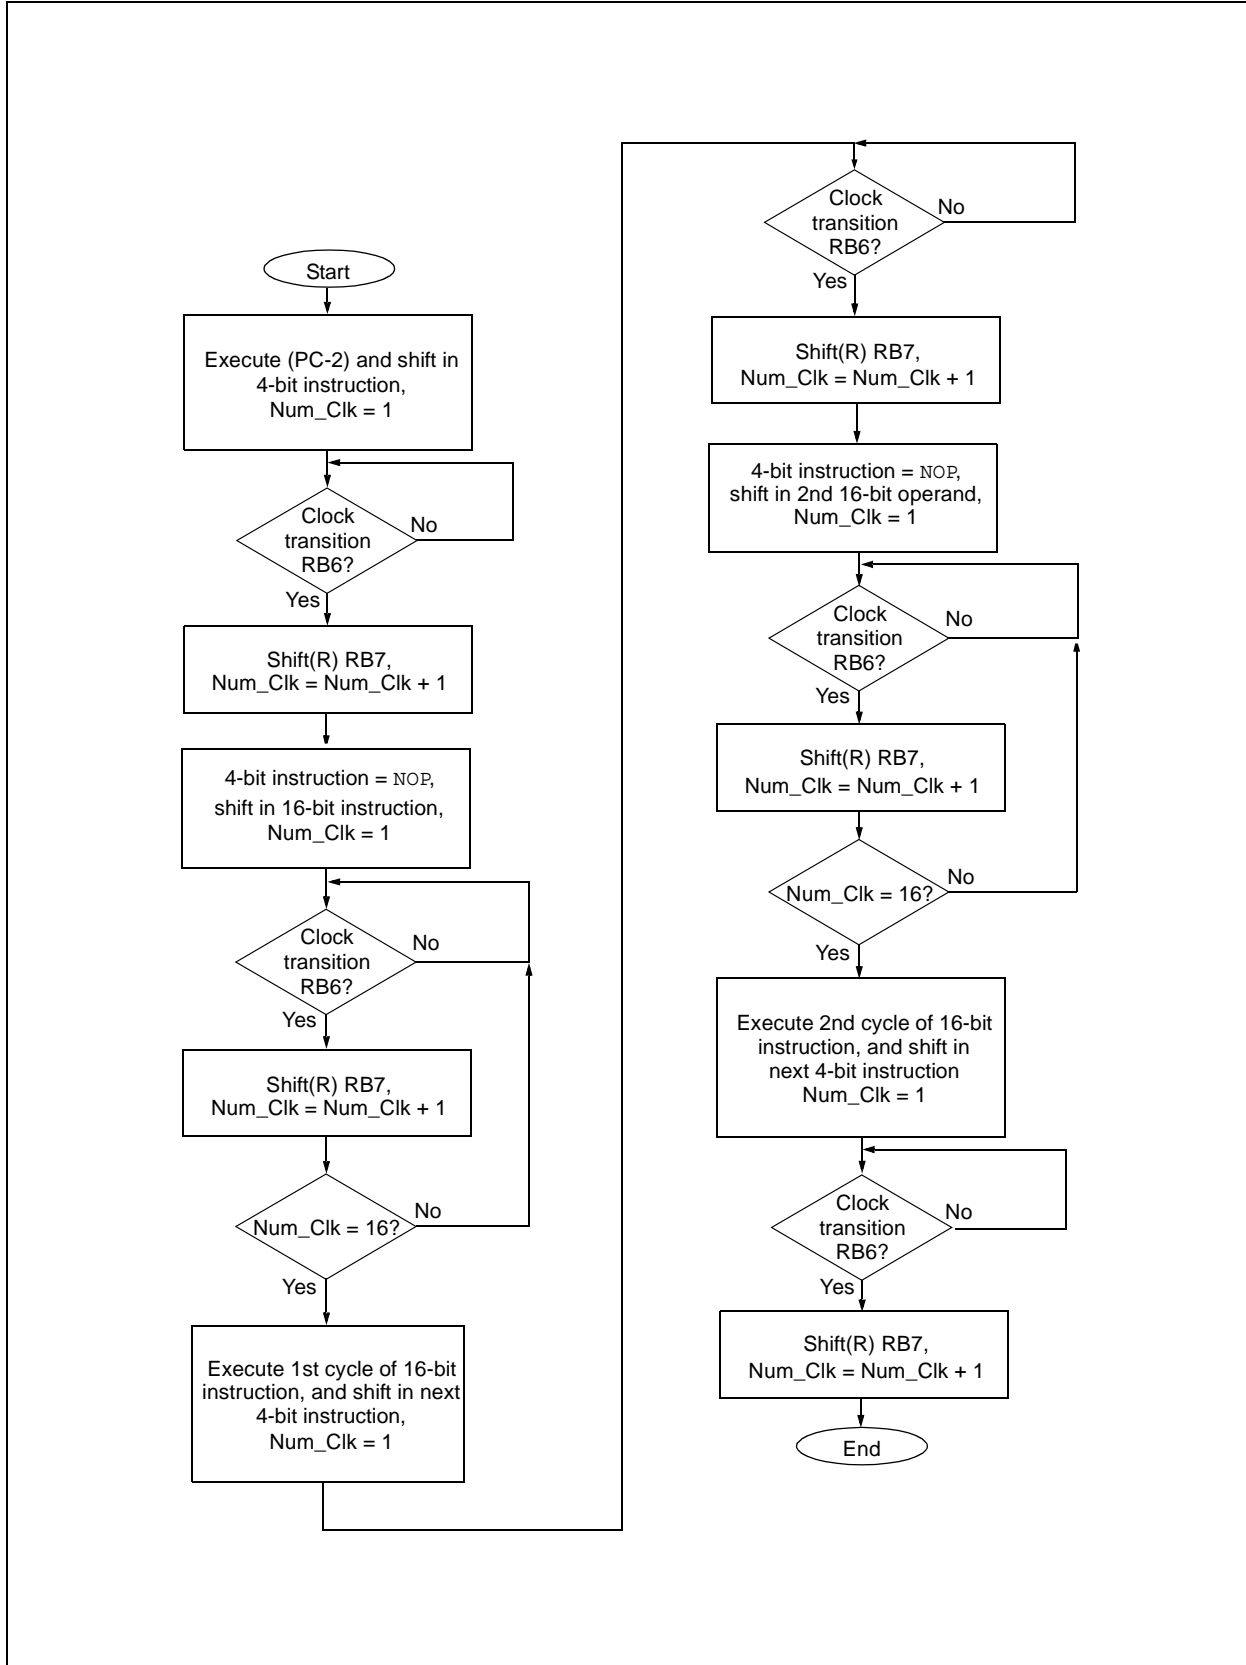

FIGURE 2-7: 16-BIT, 2-CYCLE, 2-WORD SERIAL INSTRUCTION FLOW AFTER RESET

PIC18CXX

FIGURE 2-8: 16-BIT, 2-CYCLE, 2-WORD SERIAL INSTRUCTION FLOW

2.5 TBLWT Instruction

The TBLWT instruction is a special two-cycle instruction. All forms of TBLWT instructions (post/pre-increment, post-decrement, etc.) are encoded as 4-bit special instructions. This is useful as TBLWT instructions are used repeatedly in ICSP mode. A 4-bit instruction will minimize the total number of clock cycles required to perform programming algorithms.

The TBLWT instruction sequence operates as follows:

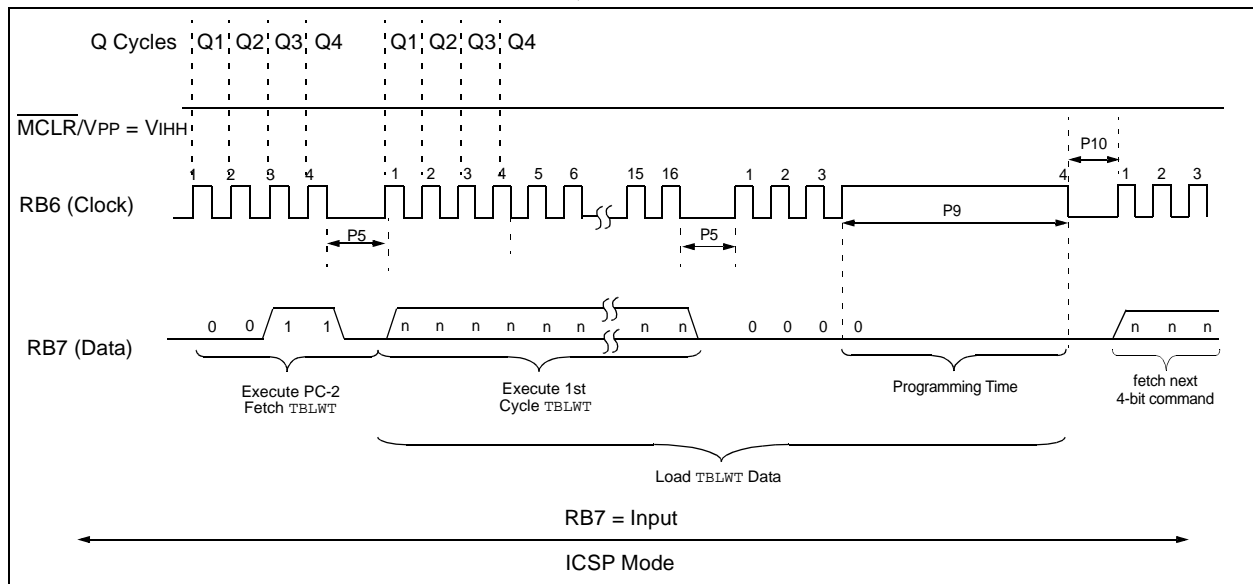

1. The 4-bit TBLWT instruction is read in by the state machine on RB7 during the four clock cycle execution of the instruction fetched previous to the TBLWT (which is a FNOP if the TBLWT is executed following a RESET).
2. Once the state machine recognizes that the instruction fetched is a TBLWT, the state machine proceeds to fetch in the 16 bits of data that will be written into the program memory location pointed to by the TBLPTR.
3. The state machine releases the CPU to execute the first cycle of the TBLWT instruction, while the first four bits of the 16-bit data word are shifted in. After the first cycle of TBLWT instruction has completed, the state machine shifts in the remaining 12 of the 16 bits of data. The data word will not be used until the second cycle of the instruction.
4. After all 16 bits of data are shifted in and the first cycle of the TBLWT is performed, the CPU will execute the second cycle of the TBLWT operation, programming the current memory location with the 16-bit value. The next instruction following the TBLWT instruction, NOP, is shifted in during the execution of the second cycle (see Figure 2-9).

The TBLWT instruction is used in ICSP mode to program the EPROM array. When writing a 16-bit value to the EPROM, ID locations, or configuration locations, the device, RB6 must be held high for the appropriate programming time during the TBLWT instruction, as specified by parameter P9.

When RB6 is asserted low, the device will cease programming the specified location.

After RB6 is asserted low, RB6 is held low for the time specified by parameter P10, to allow high voltage discharge of the program memory array.

FIGURE 2-9: TBLWT INSTRUCTION SEQUENCE

PIC18CXXX

FIGURE 2-10: TBLWT SERIAL INSTRUCTION FLOW AFTER RESET

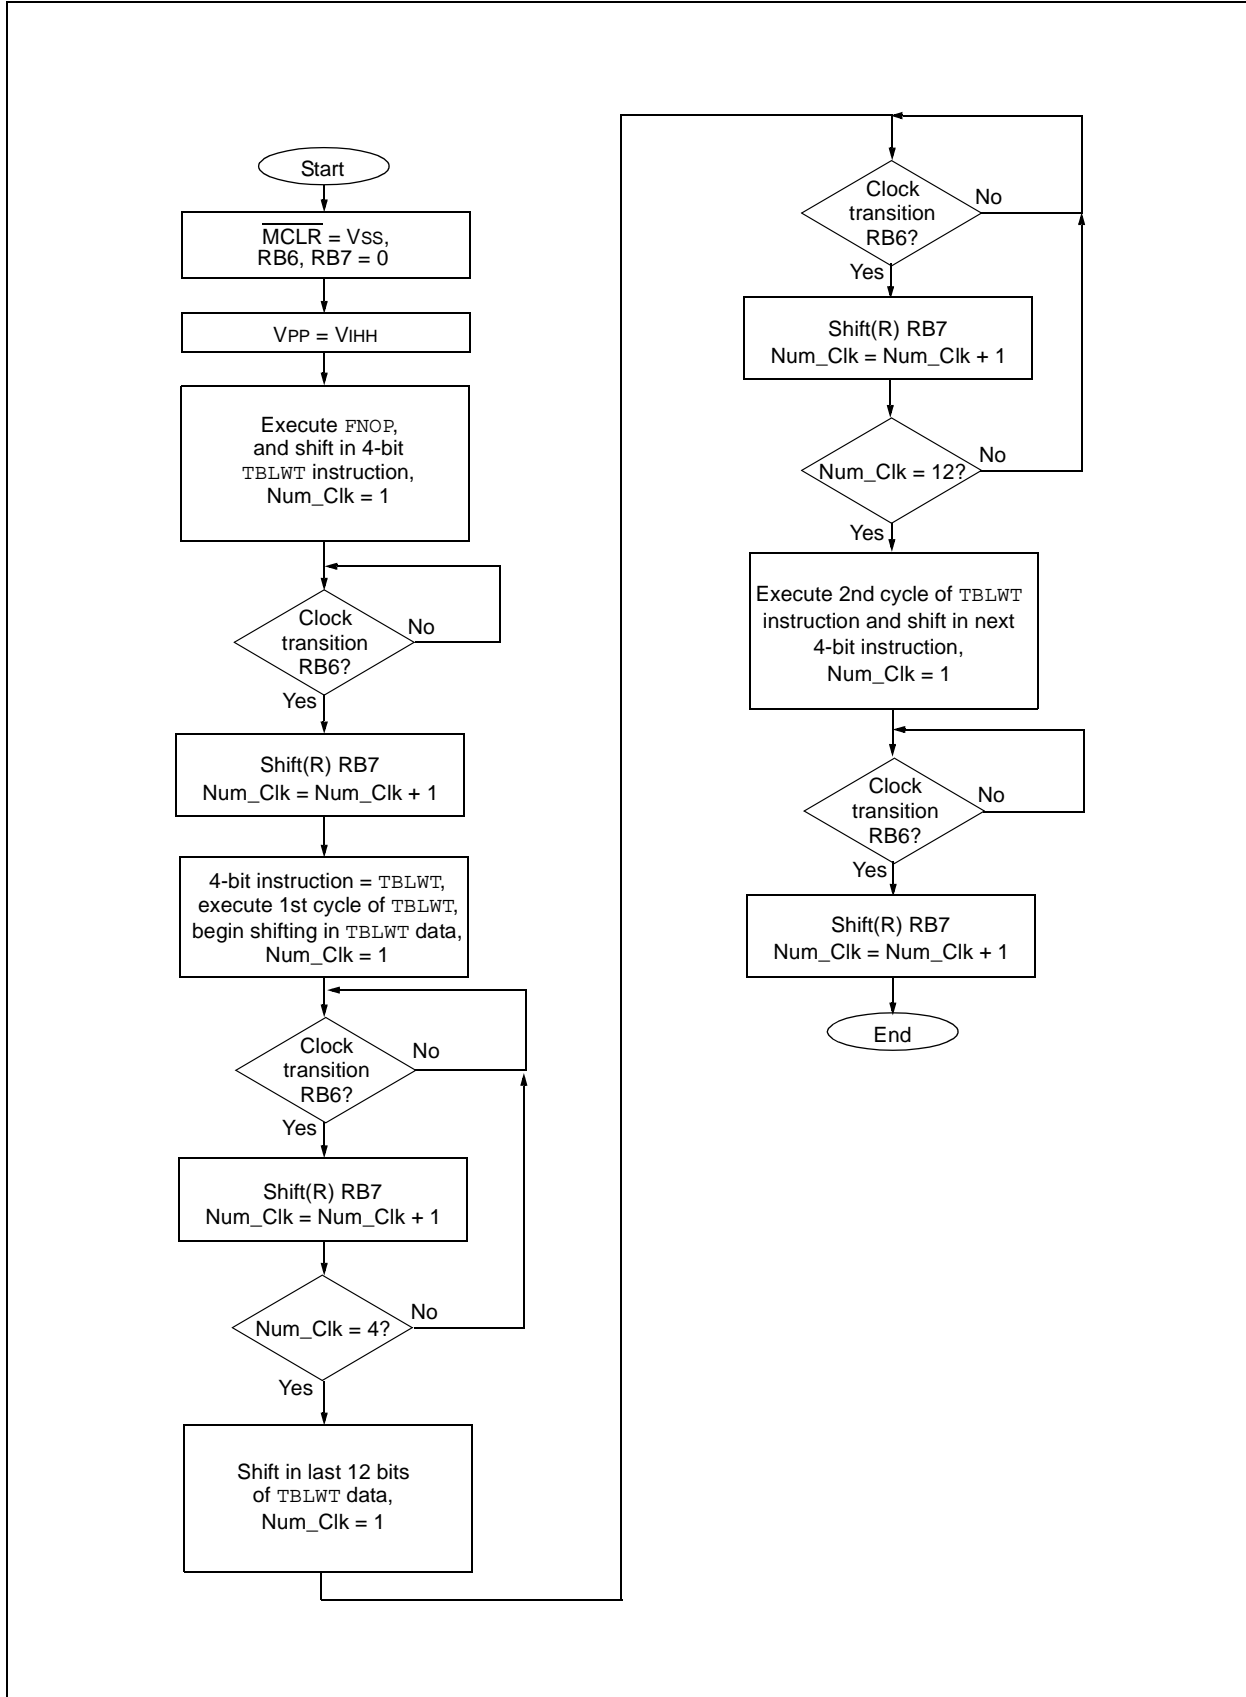

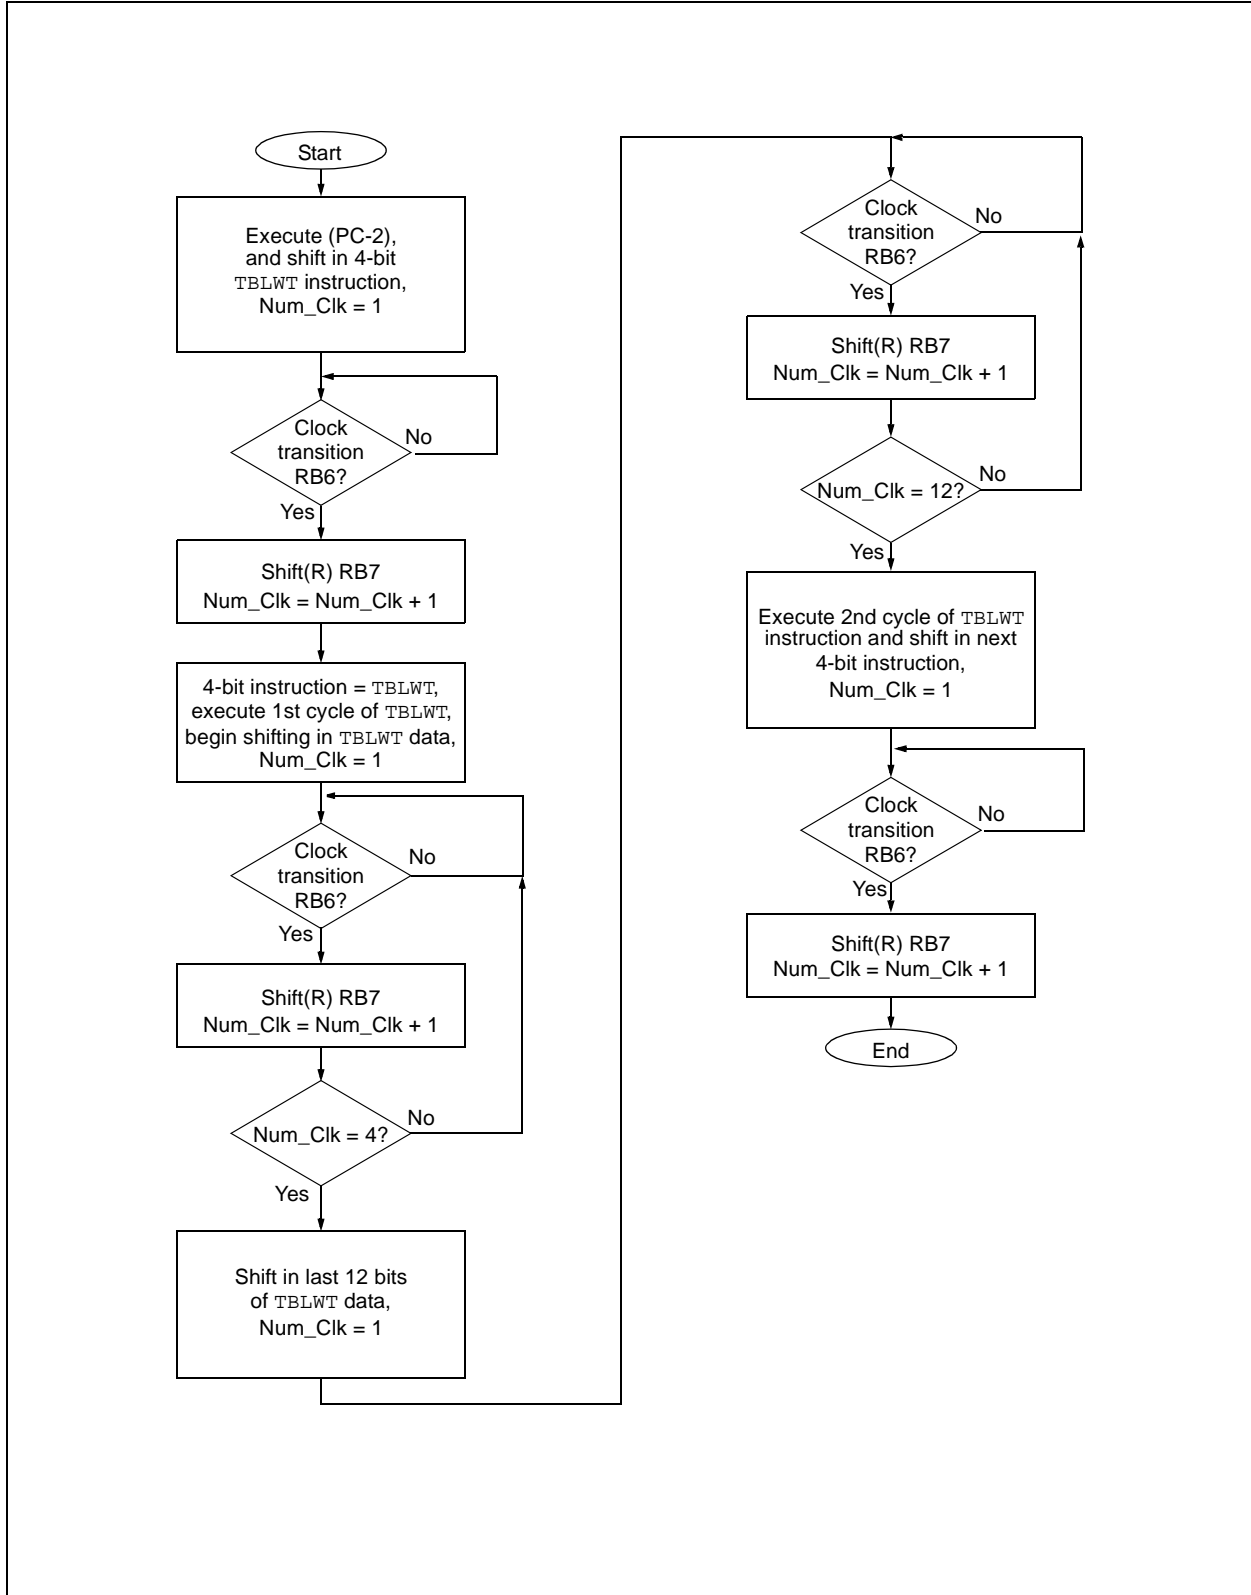

FIGURE 2-11: TBLWT SERIAL INSTRUCTION FLOW

PIC18CXXX

2.6 TBLRD Instruction

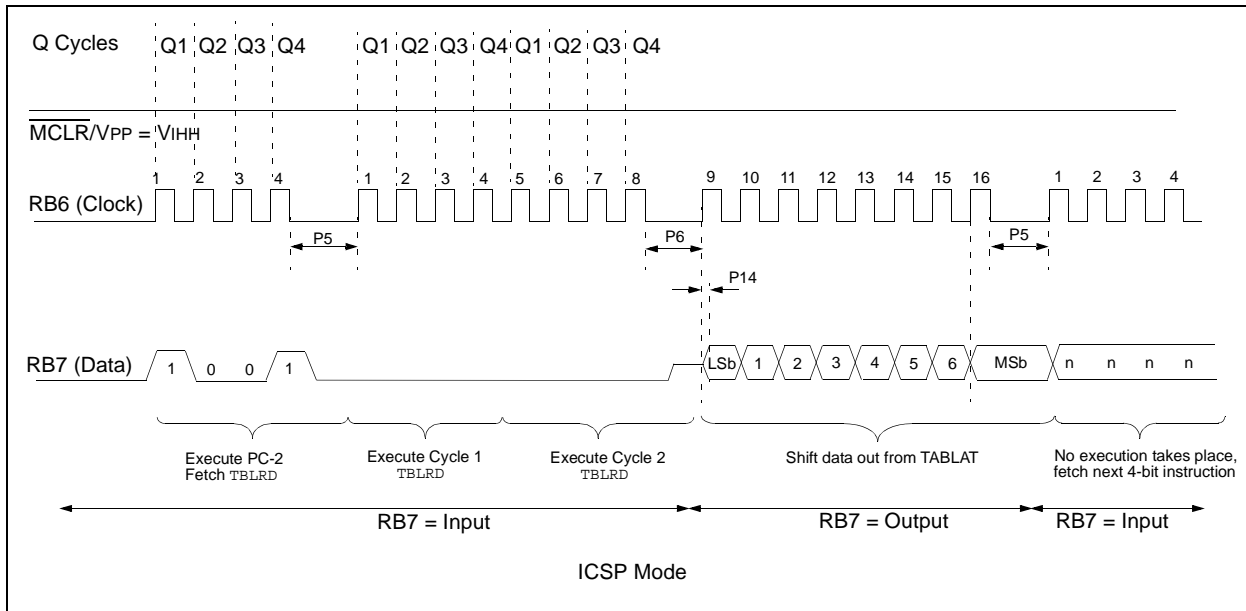

The TBLRD instruction is another special two-cycle instruction.

All forms of TBLRD instructions (post/pre-increment, post-decrement, etc.) are encoded as 4-bit special instructions. This is useful as TBLRD instructions are used repeatedly in ICSP mode. A 4-bit instruction will minimize the total number of clock cycles required to perform programming algorithms.

The TBLRD instruction sequence operates as follows:

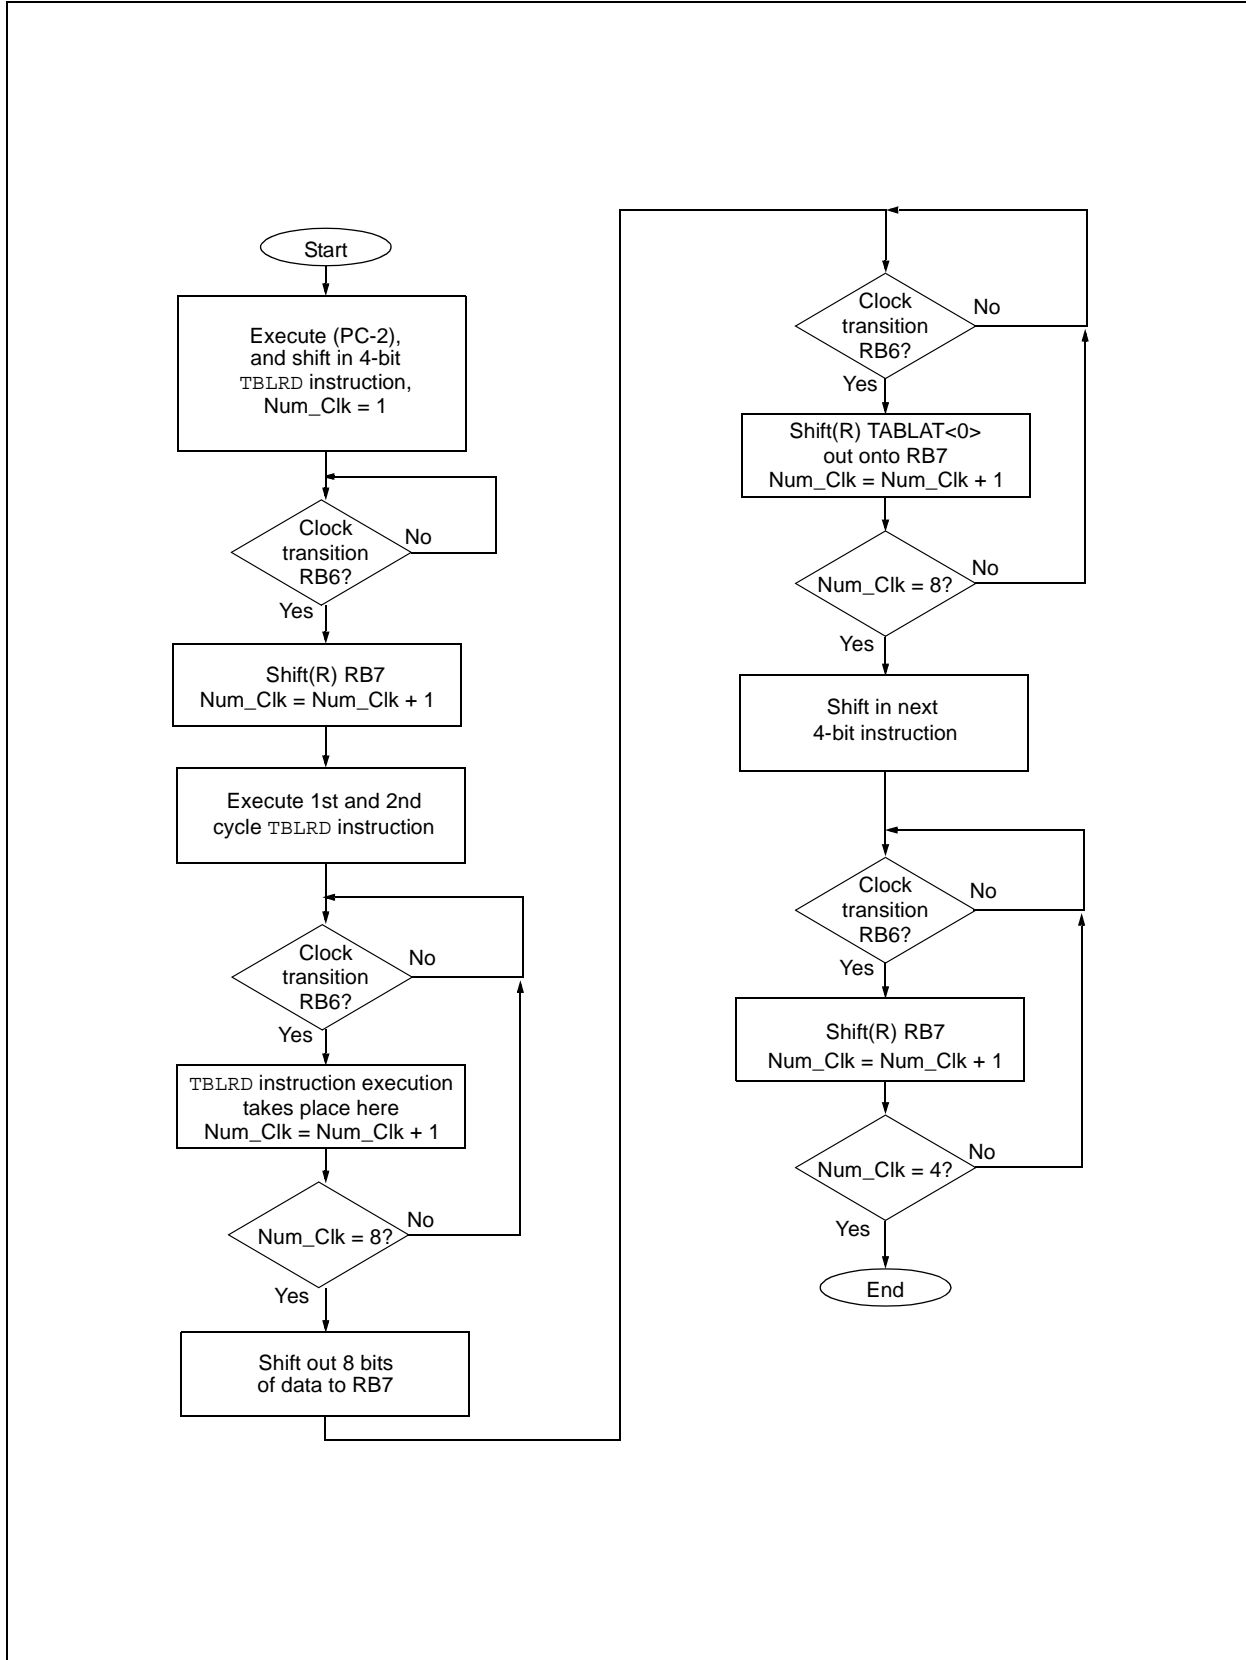

1. The 4-bit TBLRD instruction is read in by the state machine on RB7 during the four clock cycle execution of the instruction fetched previous to the TBLRD (which is an FNOP if the TBLRD is executed following a RESET).
2. Once the state machine recognizes that the instruction fetched is a TBLRD, the state machine releases the CPU and allows execution of the first and second cycles of the TBLRD instruction for eight clock cycles. When the TBLRD is performed, the contents of the program memory byte pointed to by the TBLPTR is loaded into the TABLAT register.
3. After eight clock cycles have transitioned on RB6, and the TBLRD instruction has completed, the state machine will suspend the CPU for eight clock cycles. During these eight clock cycles, the state machine configures RB7 as an output, and will shift out the contents of the TABLAT register onto RB7, LSb first.
4. When the state machine has shifted out all eight bits of data, the state machine suspends the CPU to allow an instruction pre-fetch. Four clock cycles are required on RB6 to shift in the next 4-bit instruction.

PIC18CXX

FIGURE 2-14: TBLRD SERIAL INSTRUCTION FLOW

2.6.1 SOFTWARE COMMANDS

ICSP commands of the PICmicro® MCU are supported in the PIC18CXXX family by simply combining CPU instructions. Once in the ICSP mode, instructions are loaded into a shift register, and the device waits for a command to be received. The ICSP commands for the PIC18CXXX family are now “pseudo-commands” and are shown in Table 2-2. The following sections describe how to implement the pseudo-commands using CPU instructions.

TABLE 2-2: ICSP PSEUDO COMMAND MAPPING

| ICSP™ Command | Golden Gate Instructions |
|--------------------|---|
| Load Configuration | MOVLW #Address1 |
| | MOVWF TBLPTRL |
| | MOVLW #Address2 |
| | MOVWF TBLPTRH |
| | MOVLW #Address3 |
| | MOVWF TBLPTRU |
| Load Data | Not needed. Data encoded in 4-bit TBLWT instruction sequence. |
| Read Data | TBLRD instruction |
| Increment Address | Not needed. Use TBLWT with increment/decrement (TBLWT *+/*-). |
| Load Address | MOVLW #Addr_low |
| | MOVWF TBLPTRL |
| | MOVLW #Addr_high |
| | MOVWF TBLPTRH |
| | MOVLW #Addr_upper |
| | MOVWF TBLPTRU |
| RESET Address | MOVLW #Data |
| | MOVWF TBLPTRH |
| | MOVWF TBLPTRL |
| | MOVWF TBLPTRU |
| Begin Programming | TBLWT |
| End Programming | Not needed. Programming will cease at the end of TBLWT execution. |

2.6.2 RESET ADDRESS

A reset of the program memory pointer is a write to the upper, high, and low bytes of the TBLPTR. To reset the program memory pointer, the following instruction sequence is used.

```

NOP           ; (4-BIT INSTRUCTION)
MOVLW 00h
NOP           ; (4-BIT INSTRUCTION)
MOVWF TBLPTRU ; (4-BIT INSTRUCTION)
MOVWF TBLPTRH ; (4-BIT INSTRUCTION)
NOP           ; (4-BIT INSTRUCTION)
MOVWF TBLPTRL
```

PIC18CXXX

FIGURE 2-15: RESET ADDRESS SERIAL INSTRUCTION SEQUENCE

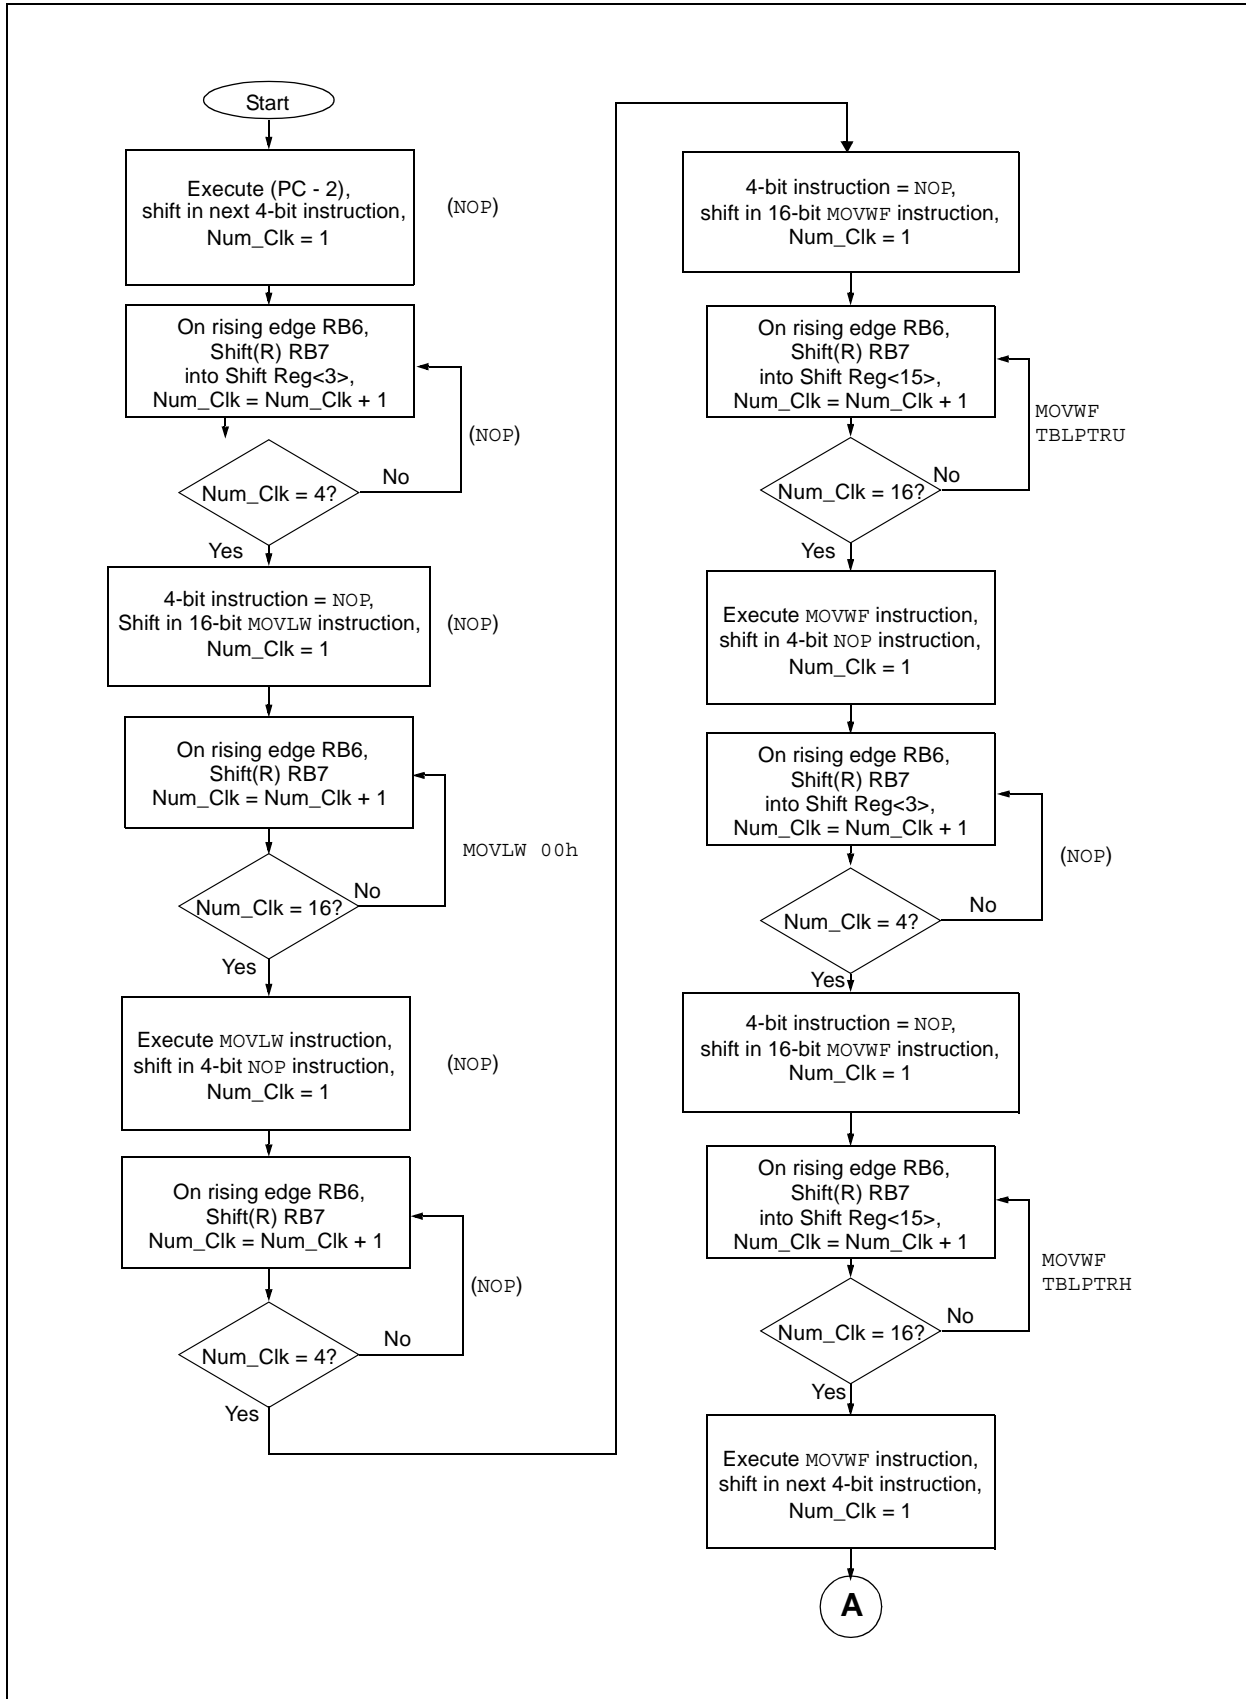

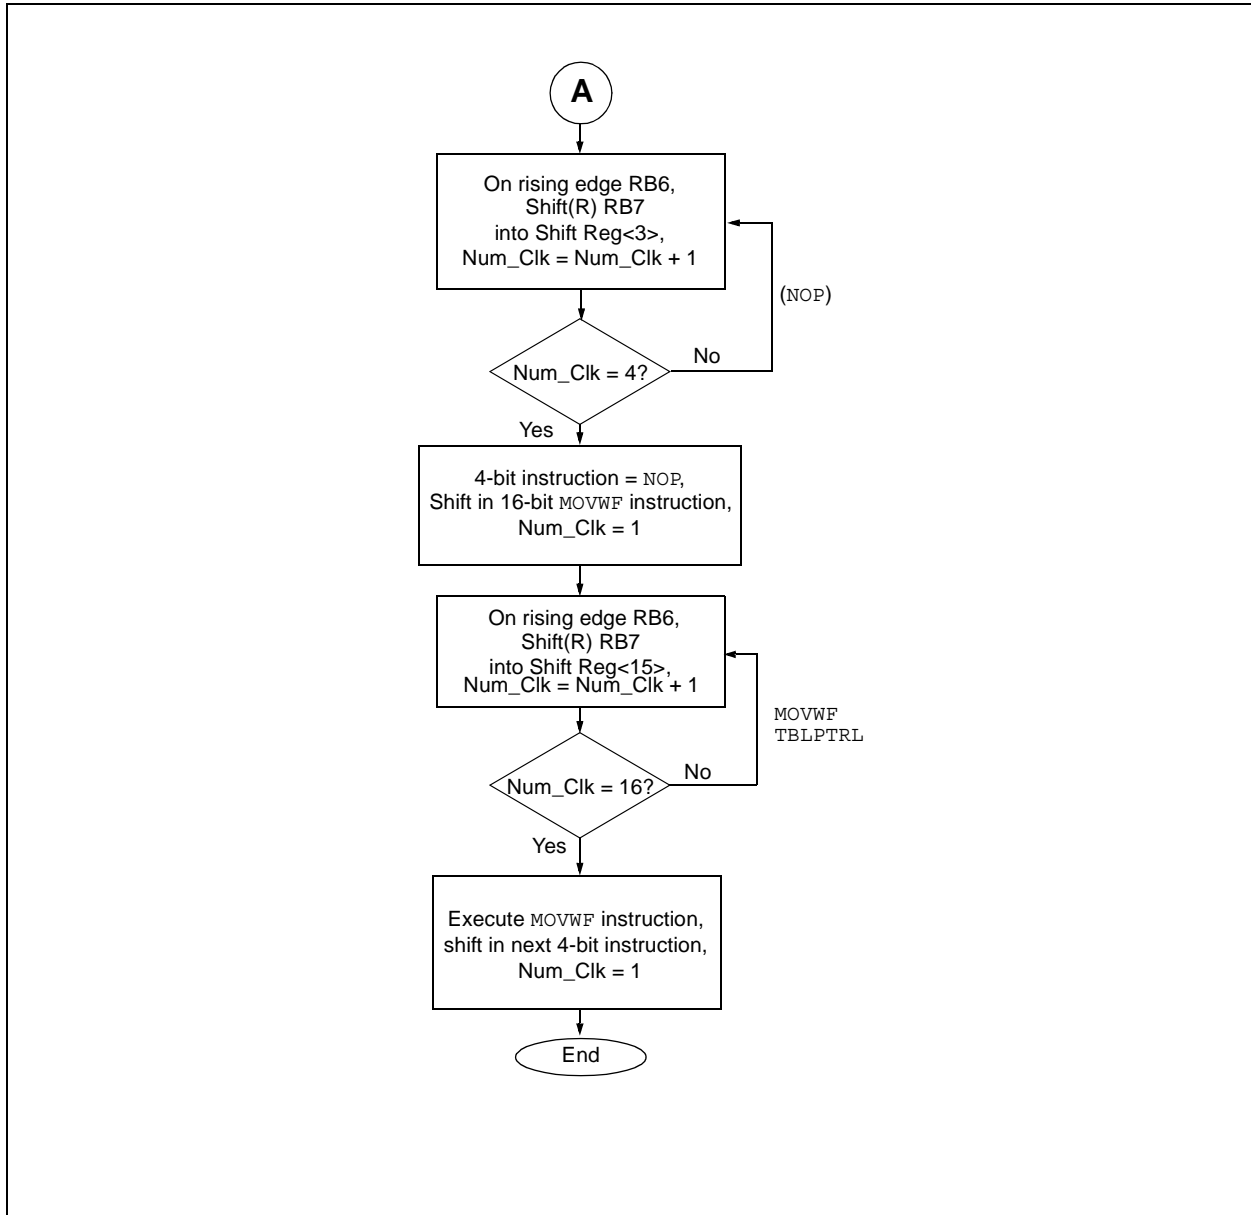

FIGURE 2-16: RESET ADDRESS SERIAL INSTRUCTION SEQUENCE (CONTINUED)

2.6.3 LOAD ADDRESS

This is used to load the address pointer to the Program Memory with a specific 22-bit value, and is useful when a specific range of locations are to be accessed. To load the address into the table pointer, the following commands must be used:

```

NOP           ; 4-bit instruction
MOVLW  Low_Address
NOP           ; 4-bit instruction
MOVWF  TBLPTRL
NOP           ; 4-bit instruction
MOVLW  High_Address
NOP           ; 4-bit instruction
MOVWF  TBLPTRH
NOP           ; 4-bit instruction
MOVLW  Upper_Address
NOP           ; 4-bit instruction
MOVWF  TBLPTRU
  
```

PIC18CXXX

FIGURE 2-17: LOAD ADDRESS SERIAL INSTRUCTION SEQUENCE

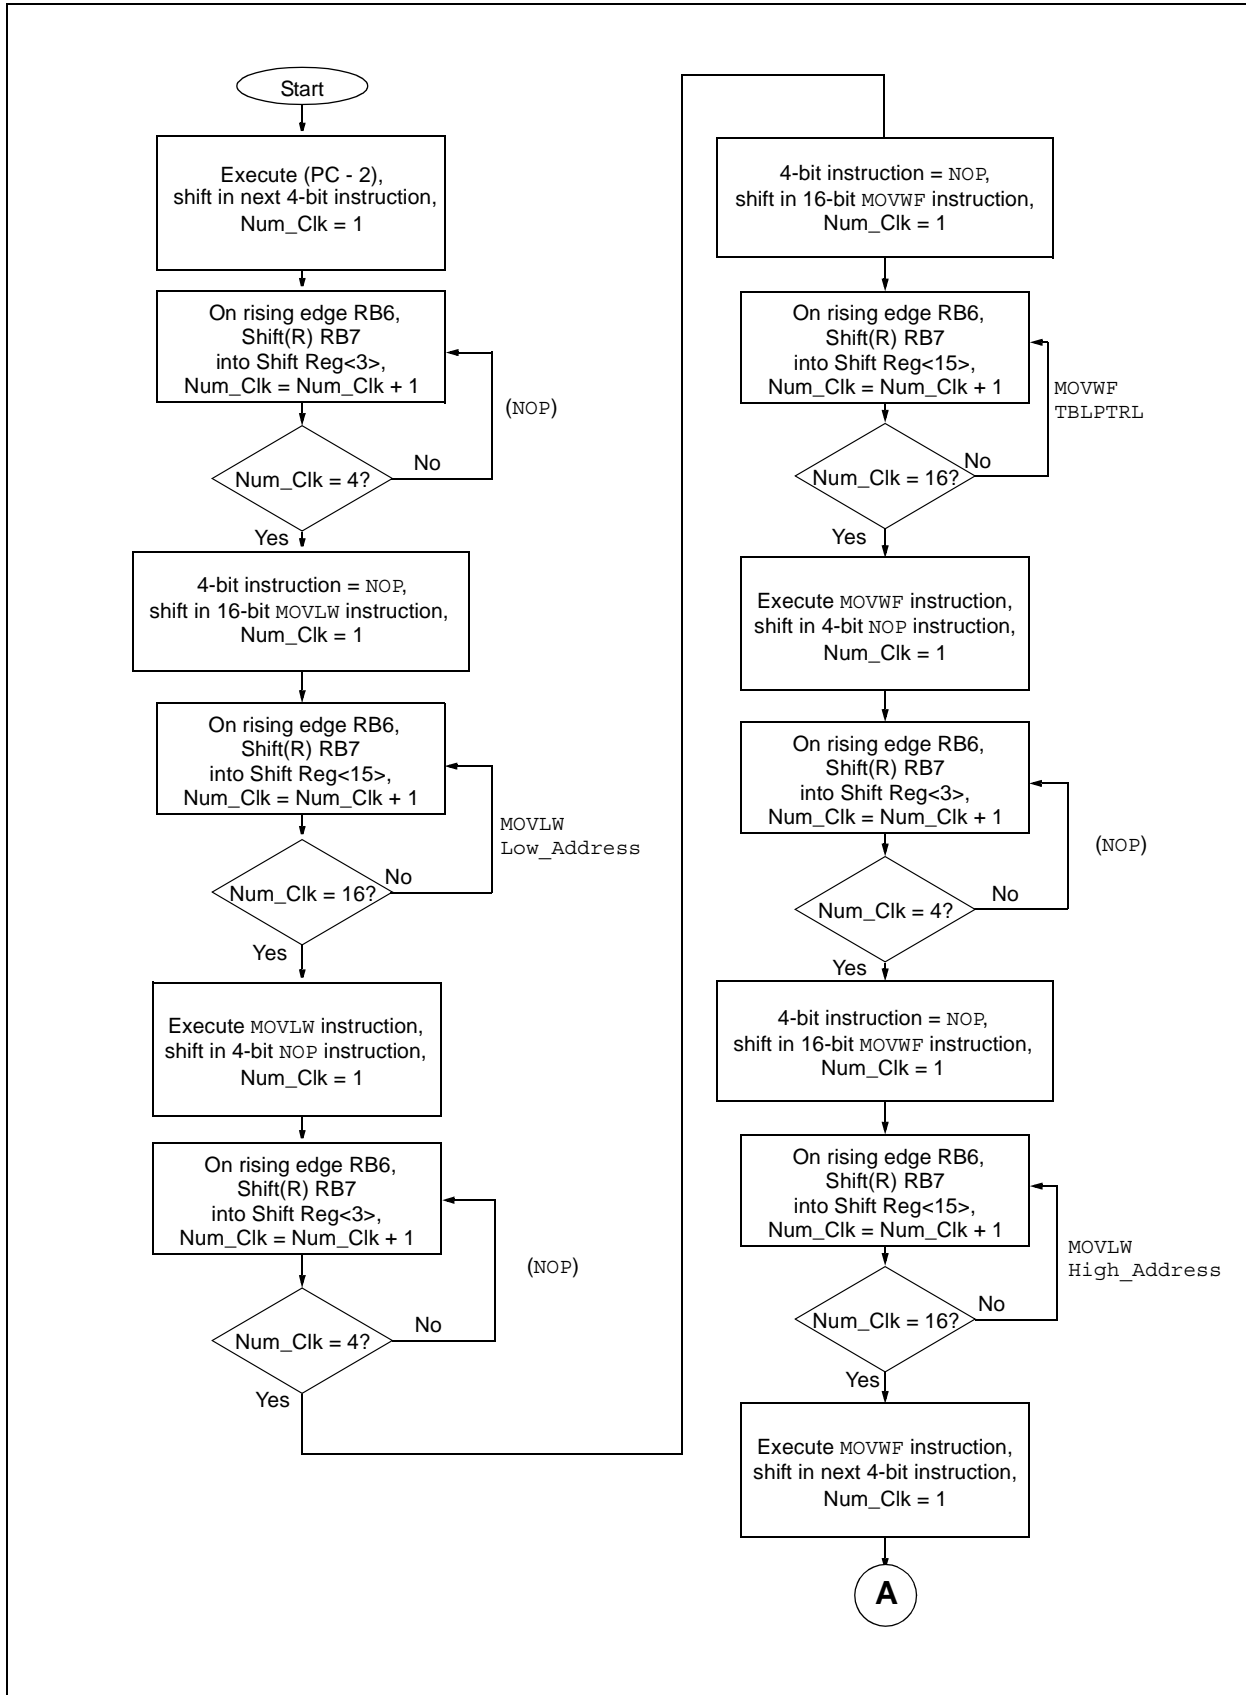

FIGURE 2-18: LOAD ADDRESS SERIAL INSTRUCTION SEQUENCE (CONTINUED)

PIC18CXXX

2.6.4 ICSP BEGIN PROGRAMMING

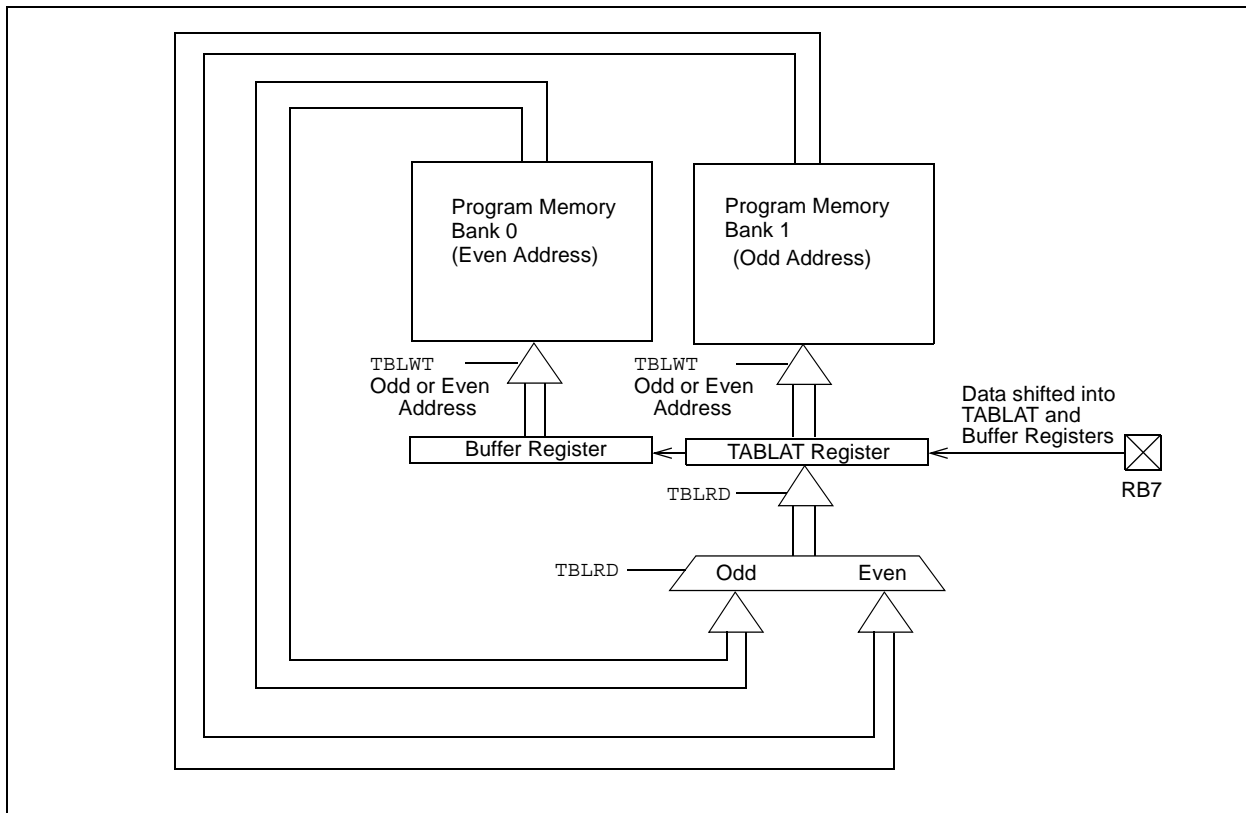

Programming is performed by executing a TBLWT instruction. In ICSP mode, the TBLWT instruction sequence will include 16 bits of data shifted into a data buffer, and then written to the word location addressed by the TBLPTR. Although the TBLPTR addresses the program memory on a byte wide boundary, all 16 bits of data shifted in during the TBLWT sequence are written at once. The 16 bits are shifted into the TABLAT and buffer registers. The TBLPTR points to the word that will be programmed; it can point to either the high or the low byte (see Figure 2-19).

The sequence for programming a location could occur as follows:

1. Set up the TBLPTR with the first address to be programmed (even or odd byte).
2. Shift in a 4-bit TBLWT instruction.
3. 16 bits of data are shifted in for programming both high and low byte of the first programmed location.
4. Execute TBLWT instruction to program location.
5. Verify high byte (odd address) by executing TBLRD*- (post-decrement). (TBLPTR points at odd address.)
6. Verify low byte (even address) by executing TBLRD*+ (post-increment). (TBLPTR points at odd address again.)
7. If location doesn't verify, go back to step 4.
8. If location does verify, begin 3x over-programming (see Section 2.6.7).

The TBLWT instruction offers flexibility with multiple addressing modes: pre-increment, post-increment, post-decrement, and no change of the TBLPTR. These modes eliminate the need for the increment address command sequence.

FIGURE 2-19: DATA BUFFERING SCHEME FOR ICSP

2.6.5 PROGRAMMING INSTRUCTION SEQUENCE

The instructions needed to execute a programming sequence are shown in the following example. Many of the instruction sequences are also shown in previous sections.

```

NOP                ; 4-bit instruction
                  ; Set up low byte
                  ; of program address
MOVLW  Low_Byte_Address ; = 00
NOP                ; 4-bit instruction
MOVWF  TBLPTRL
NOP                ; 4-bit instruction
                  ; Set up high byte
                  ; of program
                  ; address
MOVLW  High_Byte_Address ; = 00
NOP                ; 4-bit instruction
MOVWF  TBLPTRH
NOP                ; 4-bit instruction
                  ; Set up upper byte
                  ; of program
                  ; address
MOVLW  Upper_Byte_Address ; = 00
NOP                ; 4-bit instruction
MOVWF  TBLPTRU
                  ; Program data byte
                  ; included in TBLWT
                  ; instruction
                  ; sequence

TBLWT+*           ; TBLPTR = 000000h
    
```

A write of a program memory location with an odd or an even address causes a long write cycle in ICSP mode. The 16-bit data is encoded in the TBLWT sequence and is loaded into the temporary buffer register for word wide writes.

2.6.6 VERIFY SEQUENCE

The table pointer = 000001h in the last example. A TBLRD will then read the odd address byte of the current program word address location first. The verify sequence will be as follows:

```

                  ; Read/verify high byte first
TBLRD*-
                  ; TBLPTR = 0000 post-dec
                  ; Read/verify low byte
TBLRD*
    
```

The first TBLRD decrements the table pointer to point to the even address byte of the current program word. After the first and second cycle of the TBLRD are performed, all eight bits of data are shifted out on RB7. The fetch of the second TBLRD occurs on the next four clock cycles. The second TBLRD does not modify the table pointer address. This allows another programming cycle (TBLWT+*) to take place if the verify doesn't match the program data, without having to update the table pointer.

If the contents of the verify do not match the intended program data word, then the TBLWT instruction must be repeated with the correct contents of the current program word. Therefore, only one instruction needs to be performed to repeat the programming cycle:

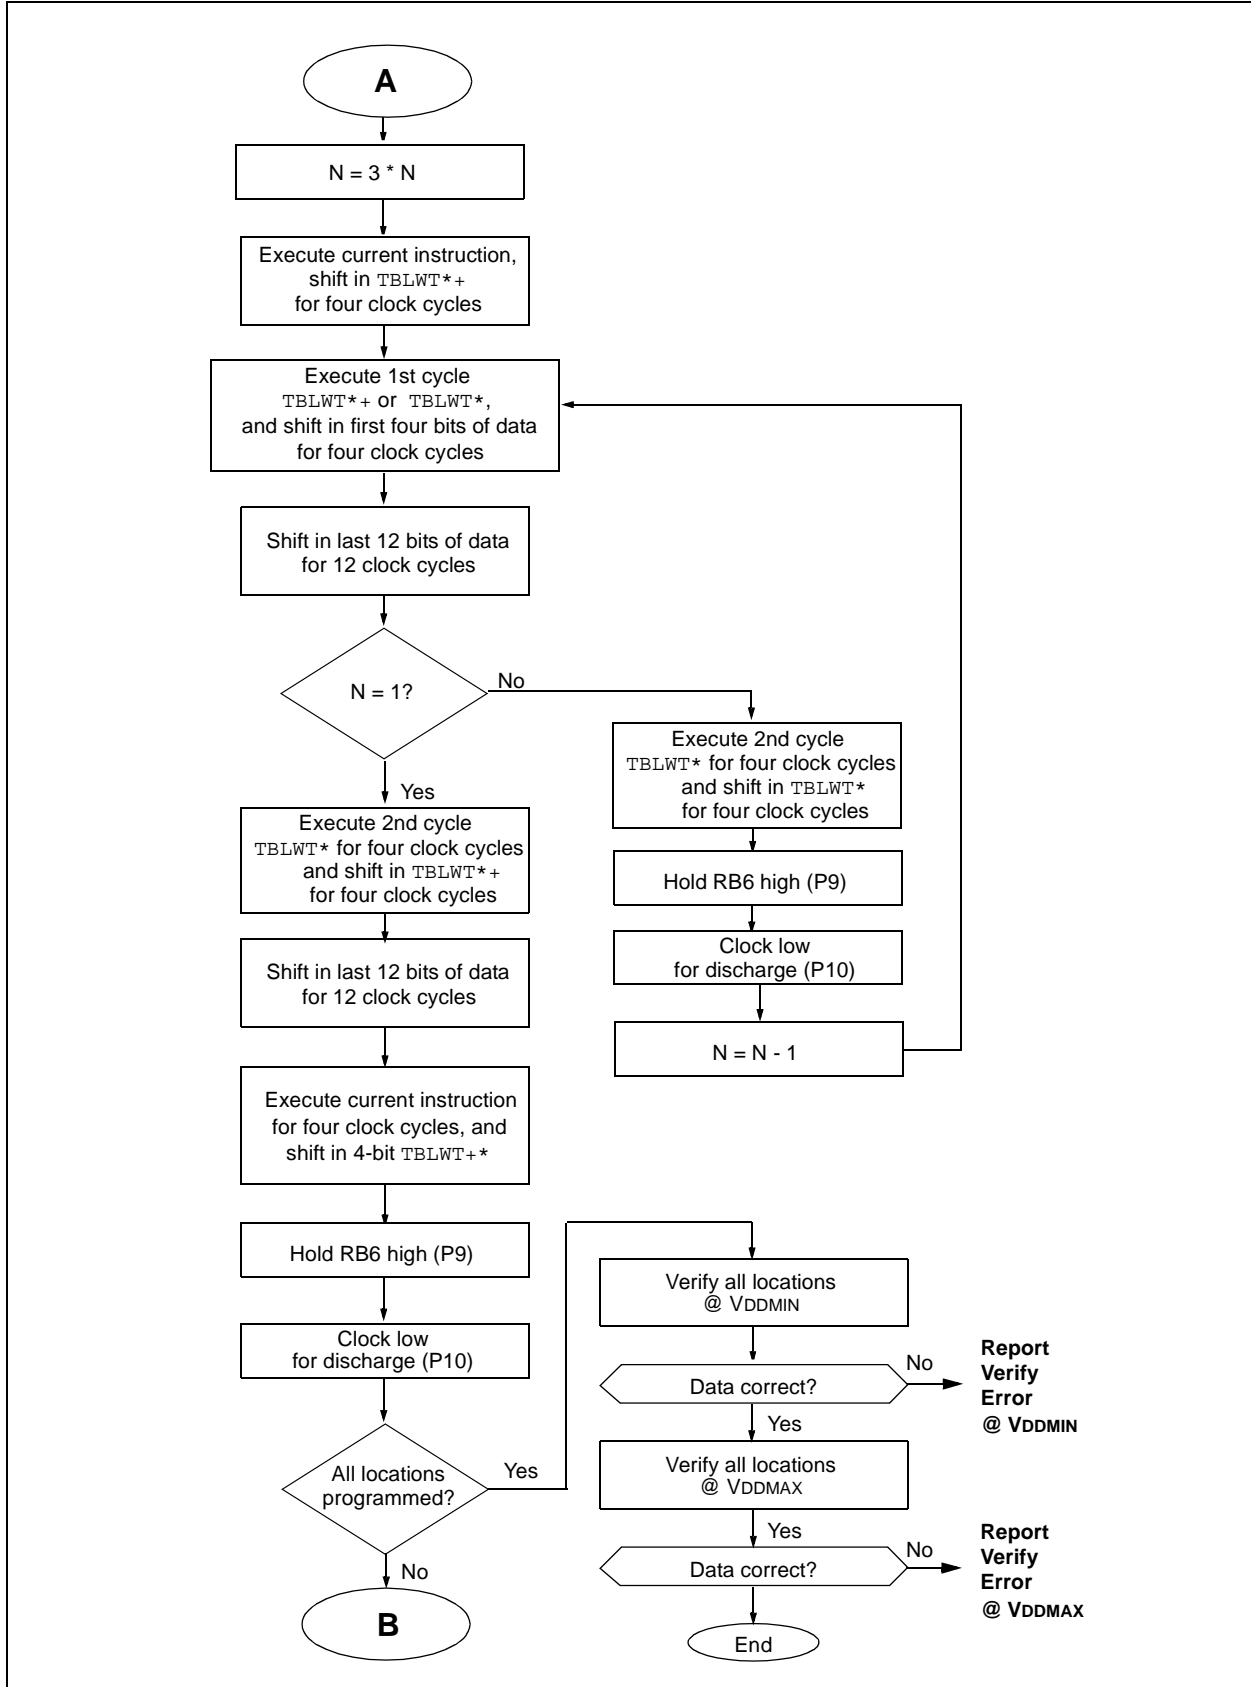

```
TBLWT+*
```

2.6.7 3X OVER-PROGRAMMING

Once a location has been both programmed and verified over the range of voltages, 3x over-programming should be applied. In other words, apply three times the number of programming pulses required to program a location in memory to ensure solid programming margin.

This means that every location will be programmed a minimum of four times (1 + 3x over-programming).

FIGURE 2-21: DETAILED PROGRAMMING FLOW CHART – PROGRAM MEMORY (CONTINUED)

PIC18CXXX

2.6.8 LOAD CONFIGURATION

The Configuration registers are located in test memory, and are only addressable when the high address bit of the TBLPTR (bit 21) is set. Test program memory contains test memory, configuration registers, calibration registers, and ID locations. The desired address must be loaded into all three bytes of the table pointer to program specific ID locations, or the configuration bits. To program the configuration registers, the following sequence must be followed:

```

NOP                ; 4-bit instruction
                   ; shift in 16-bit
                   ; MOVLW instruction
MOVLW  03h
NOP                ; 4-bit instruction
                   ; shift in 16-bit
                   ; MOVWF instruction
                   ; Enable Test memory
MOVWF  TBLPTRU
NOP                ; 4-bit instruction
                   ; shift in 16-bit
                   ; MOVLW instruction
MOVLW  Low_Config_Address
NOP                ; 4-bit instruction
                   ; shift in 16-bit
                   ; MOVWF instruction
MOVWF  TBLPTRL
NOP                ; 4-bit instruction
                   ; shift in 16-bit
                   ; MOVLW instruction
MOVLW  High_Config_Address
NOP                ; 4-bit instruction
                   ; shift in 16-bit
                   ; MOVWF instruction
MOVWF  TBLPTRH
NOP                ; 4-bit instruction
                   ; shift in 16-bit
                   ; MOVLW instruction
TBLWT*+
                   ; 16-bits of data are
                   ; shifted in for write
                   ; of config1L and
                   ; config1H TBLWT is a
                   ; 4-bit special
                   ; instruction.
                   ; Wait P9 for
                   ; programming
```

2.6.9 END PROGRAMMING

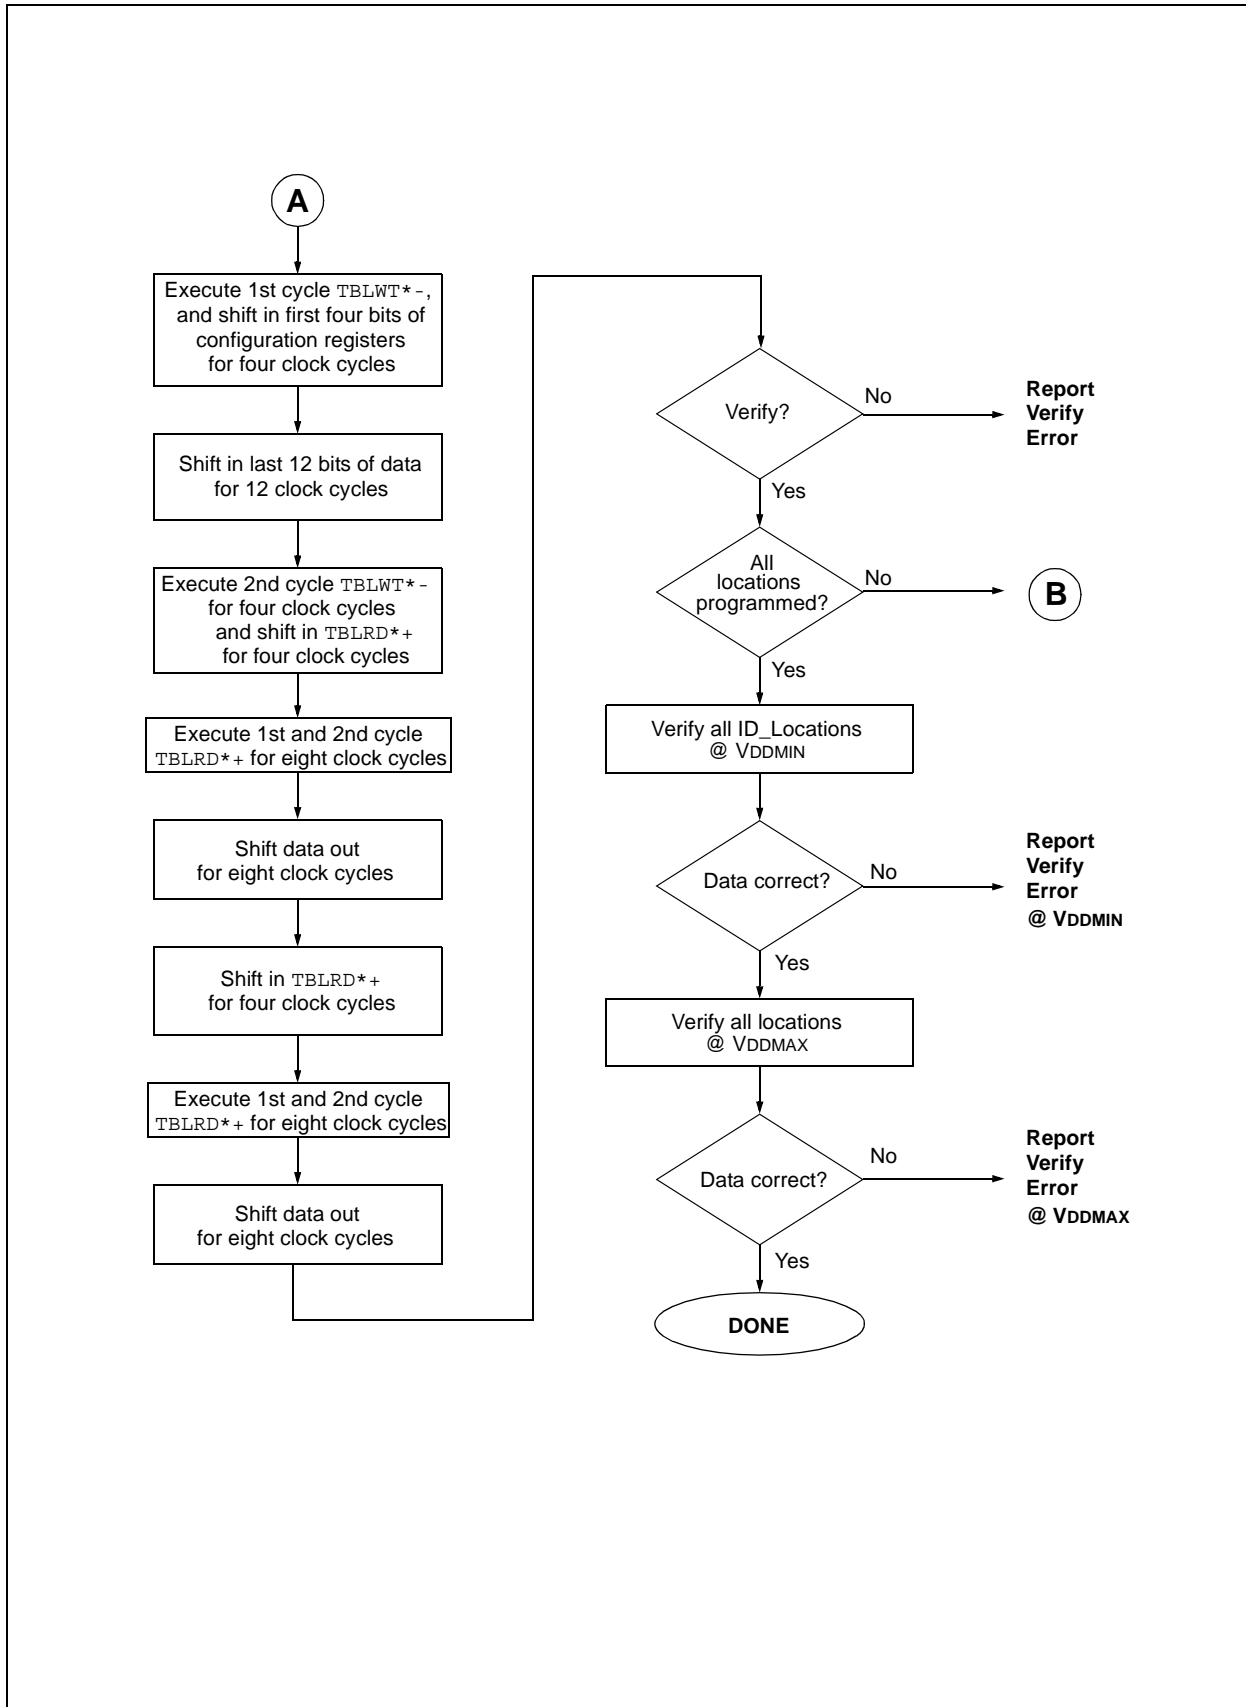

When programming occurs, 16 bits of data are programmed into memory. The 16 bits of data are shifted in during the TBLWT sequence. After the programming command (TBLWT) has been executed, the user must wait P9 until programming is complete, before another command can be executed by the CPU. There is no command to end programming.

RB6 must remain high for as long as programming is desired. When RB6 is lowered, programming will cease.

After the falling edge occurs on RB6, RB6 must be held low for a period of time (Parameter 10), so a high voltage discharge can be performed. This ensures the program array isn't stressed at high voltage during execution of the next instruction. The high voltage discharge will occur while RB6 is low, following the programming time.

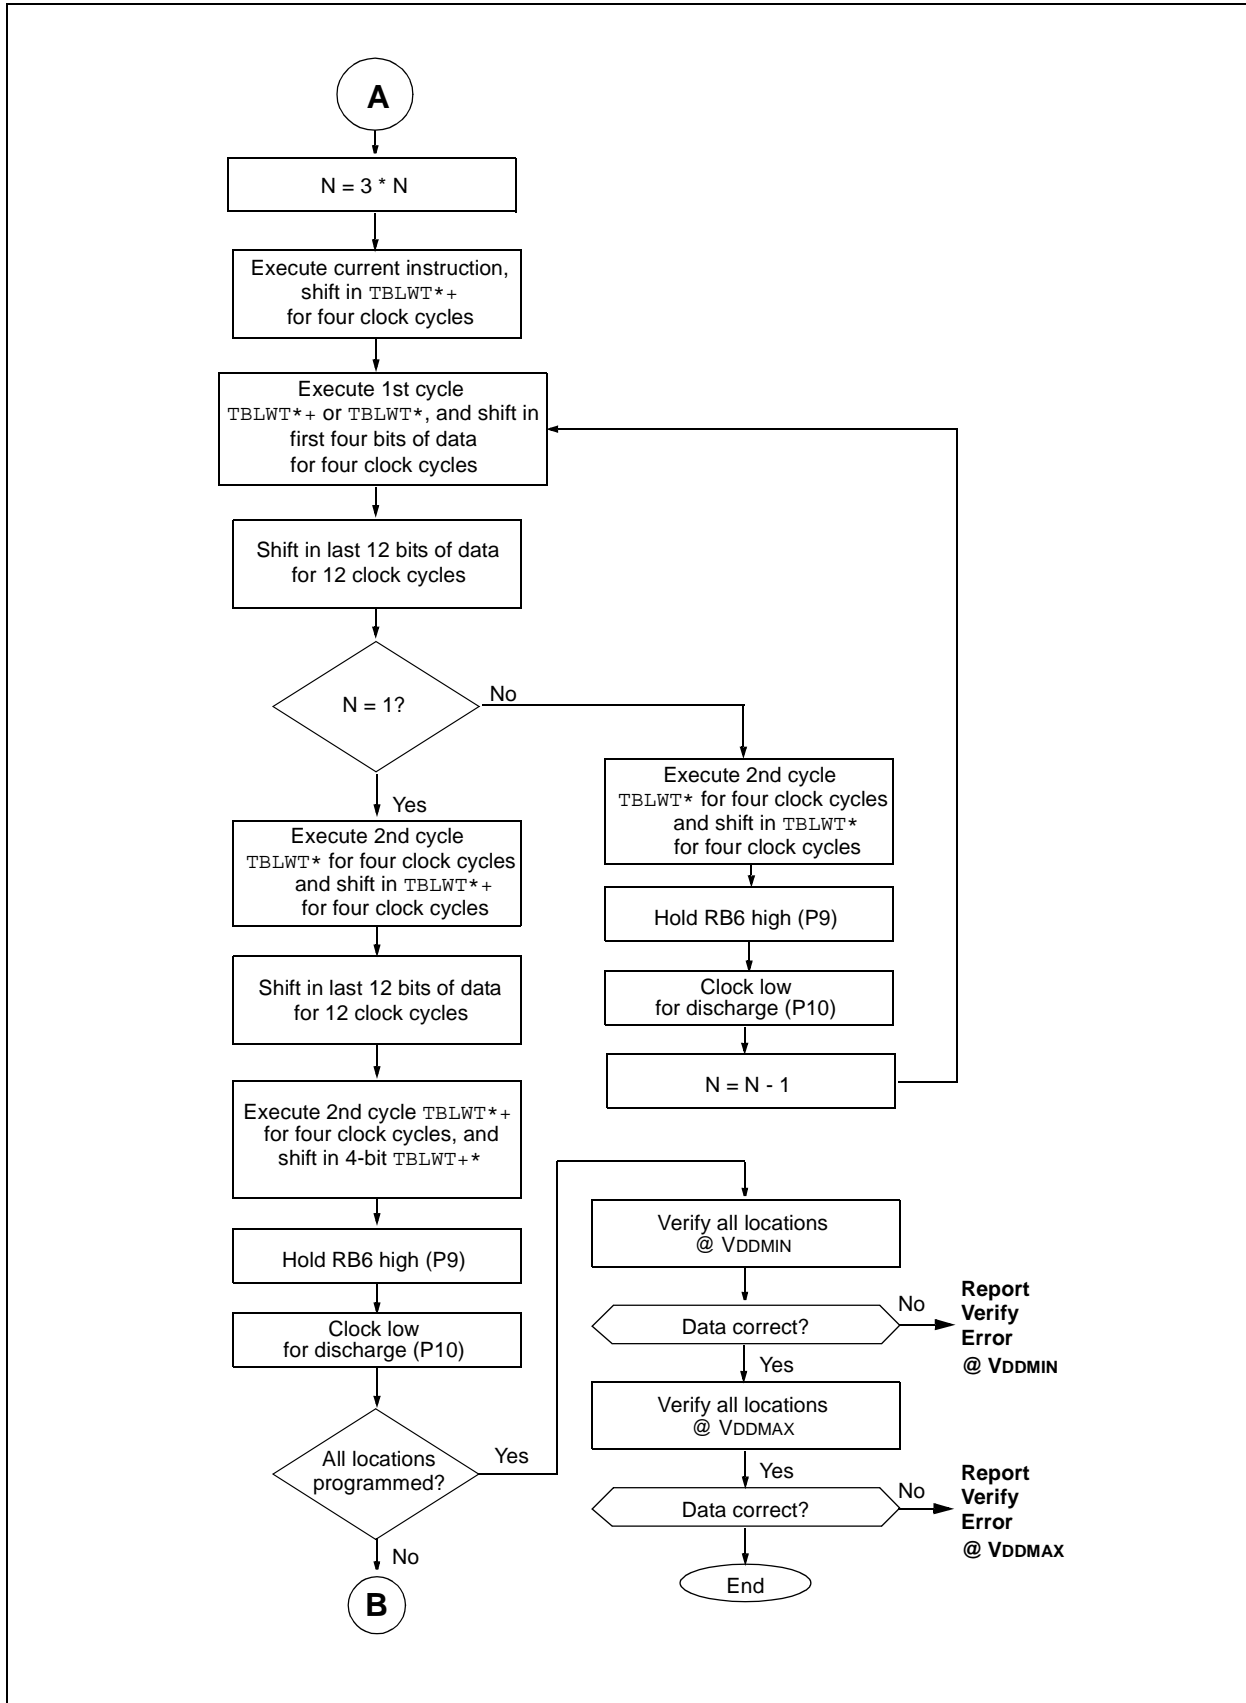

PIC18CXXX

FIGURE 2-23: DETAILED PROGRAMMING FLOW CHART – CONFIG WORD

PIC18CXXX

FIGURE 2-25: DETAILED PROGRAMMING FLOW CHART – ID LOCATION (CONTINUED)

3.0 CONFIGURATION WORD

The configuration bits can be programmed (read as '0'), or left unprogrammed (read as '1'), to select various device configurations. These bits are mapped starting at program memory location 300000h.

The user will note that address 300000h is beyond the user program memory space. In fact, it belongs to the configuration memory space (300000h – 3FFFFFFh).

3.1 ID Locations

A user may store identification information (ID) in eight ID locations mapped in [0x200000:0x200007]. It is recommended that the user use only the four Least Significant bits of each ID location.

The ID locations do not read out in a scrambled fashion after code protection is enabled. For all devices, it is recommended to write ID locations as '1111 bbbb' where 'bbbb' is the ID information.

Note: The PIC18C601/801 devices do not have user ID locations.

TABLE 3-1: 18CXX2 CONFIGURATION BITS AND DEVICE IDS

| File Name | Bit 7 | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 | Default/ Unprogrammed Value | |
|-----------|----------|-------|-------|--------|-------|--------|--------|--------|-----------------------------------|-----------|

PIC18CXXX

TABLE 3-4: PIC18CXXX FAMILY CONFIGURATION BITS

| Bit Name | Bit Type | File Name/Devices | Description |
|----------------------------|----------|--------------------------------|---|
| CP | R/P – 1 | CONFIG1L/ 18CXX2 and 18CXX8 | Code Protection bits 1 = Program memory code protection off 0 = All of program memory code protected |
| $\overline{\text{OSCSEN}}$ | R/P – 1 | CONFIG1H/ 18CXX2 and 18CXX8 | Oscillator System Clock Switch Enable bit 1 = Oscillator system clock switch option is disabled (main oscillator is source) 0 = Oscillator system clock switch option is enabled (oscillator switching is enabled) |
| FOSC2: FOSC0 | R/P – 1 | CONFIG1H/ 18CXXX | Oscillator Selection bits 111 = RC oscillator w/OSC2 configured as RA6 (reserved on PIC18C601/801) 110 = HS oscillator with PLL enabled/Clock frequency = (4 X Fosc) (reserved on PIC18C601/801) 101 = EC oscillator w/OSC2 configured as RA6 (reserved on PIC18C601/801) 100 = EC oscillator w/OSC2 configured as divide by 4 clock output (reserved on PIC18C601/801) 011 = RC oscillator 010 = HS oscillator 001 = XT oscillator 000 = LP oscillator |
| BORV1: BORV0 | R/P – 1 | CONFIG2L/ 18CXX2 and 18CXX8 | Brown-out Reset Voltage bits 11 = VBOR set to 2.5V 10 = VBOR set to 2.7V 01 = VBOR set to 4.2V 00 = VBOR set to 4.5V |
| BOREN | R/P – 1 | CONFIG2L/ 18CXX2 and 18CXX8 | Brown-out Reset Enable bit 1 = Brown-out Reset enabled 0 = Brown-out Reset disabled |
| $\overline{\text{PWRTEN}}$ | R/P – 1 | CONFIG2L/ 18CXXX | Power-up Timer Enable bit 1 = PWRT disabled 0 = PWRT enabled Enabling Brown-out Reset automatically enables the Power-up Timer (PWRT), regardless of the value of bit $\overline{\text{PWRTEN}}$. Ensure Power-up Timer is enabled when Brown-out Reset is enabled. |
| WDTPS2: WDTPS0 | R/P – 1 | CONFIG2H/ 18CXXX | Watchdog Timer Postscale Select bits 111 = 1:128 110 = 1:64 101 = 1:32 100 = 1:16 011 = 1:8 010 = 1:4 001 = 1:2 000 = 1:1 |

Legend: R = readable, P = programmable, U = unimplemented, read as '0',
- n = value when device is unprogrammed, u = unchanged.

TABLE 3-4: PIC18CXXX FAMILY CONFIGURATION BITS (CONTINUED)

| Bit Name | Bit Type | File Name/Devices | Description |
|------------|----------|-------------------------|---|
| WDTEN | R/P – 1 | CONFIG2H/ 18CXXX | Watchdog Timer Enable bit 1 = WDT enabled 0 = WDT disabled (control is placed on SWDTEN bit) |
| CCP2MX | R/P – 1 | CONFIG3H/ 18CXX2 | CCP2 Mux bit 1 = CCP2 input/output is multiplexed with RC1 0 = CCP2 input/output is multiplexed with RB3 |
| STVREN | R/P – 1 | CONFIG4L/ 18CXXX | Stack Overflow/Underflow Reset Enable bit 1 = Stack Overflow/Underflow will cause RESET 0 = Stack Overflow/Underflow will not cause RESET |
| BW | R/P – 1 | CONFIG2L/ 18C601/801 | External Bus Data Width bit 1 = 16-bit External Bus mode 0 = 8-bit External Bus mode |
| DEV10:DEV3 | R | DEVID2/ 18CXXX | Device ID bits These bits are used with the DEV2:DEV0 bits in the DEVID1 register to identify part number. |
| DEV2:DEV0 | R | DEVID1/ 18CXXX | Device ID bits These bits are used with the DEV10:DEV3 bits in the DEVID2 register to identify part number. |
| REV4:REV0 | R | DEVID1/ 18CXXX | These bits are used to indicate the revision of the device. |

Legend: R = readable, P = programmable, U = unimplemented, read as '0',
- n = value when device is unprogrammed, u = unchanged.

PIC18CXXX

3.2 Embedding Configuration Word Information in the HEX File

To allow portability of code, a PIC18CXXX programmer is required to read the configuration word locations from the HEX file when loading the HEX file. If configuration word information was not present in the HEX file, then a simple warning message may be issued. Similarly, while saving a HEX file, all configuration word information must be included. An option to not include the configuration word information may be provided. When embedding configuration word information in the HEX file, it should be to address FE00h.

Microchip Technology Inc. feels strongly that this feature is important for the benefit of the end customer.

3.3 Checksum Computation

The checksum is calculated by summing the following:

- The contents of all program memory locations
- The configuration word, appropriately masked
- Masked ID locations (when applicable)

The Least Significant 16 bits of this sum are the checksum.

Table 3-5 describes how to calculate the checksum for each device. Note that the checksum calculation differs depending on the code protect setting. Since the program memory locations read out differently, depending on the code protect setting, the table describes how to manipulate the actual program memory values to simulate the values that would be read from a protected device. When calculating a checksum by reading a device, the entire program memory can simply be read and summed. The configuration word and ID locations can always be read.

Note that some older devices have an additional value added in the checksum. This is to maintain compatibility with older device programmer checksums.

Note: The checksum computations are shown only for devices with on-chip EPROM (i.e., PIC18CXX2 and PIC18CXX8 devices). Because PIC18C601/801 devices do not have on-chip EPROM, no formulas are shown for them. The decision to implement a checksum for these devices, as well as the details of the checksum scheme, are left to the discretion of the user.

TABLE 3-5: CHECKSUM COMPUTATION

| Device | Code Protect | Checksum | Blank Value | 0xAA at 0 and Max Address |
|-----------|--------------|--|-------------|---------------------------|
| PIC18C242 | Disabled | SUM[0x0000:0x3FFF] + CONFIG1L & 0xFF + CONFIG1H & 0x27 + CONFIG2L & 0x0F + CONFIG2H & 0x0F + CONFIG3H & 0x01 + CONFIG4L & 0x01 | 0xC146 | 0xC09C |

† Data in "Typ" column is at 5V, 25°C, unless otherwise stated.

Note the following details of the code protection feature on PICmicro® MCUs.

- The PICmicro family meets the specifications contained in the Microchip Data Sheet.
- Microchip believes that its family of PICmicro microcontrollers is one of the most secure products of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the PICmicro microcontroller in a manner outside the operating specifications contained in the data sheet. The person doing so may be engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable”.
- Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our product.

If you have any further questions about this matter, please contact the local sales office nearest to you.

Microchip received QS-9000 quality system certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona in July 1999. The Company's quality system processes and procedures are QS-9000 compliant for its PICmicro® 8-bit MCUs, KEELoc® code hopping devices, Serial EEPROMs and microperipheral products. In addition, Microchip's quality system for the design and manufacture of development systems is ISO 9001 certified.
