# Description

The M30201 group of single-chip microcomputers are built using the high-performance silicon gate CMOS process using a M16C/60 Series CPU core. M30201 group is packaged in a 52-pin plastic molded SDIP, or 56-pin plastic molded QFP. These single-chip microcomputers operate using sophisticated instructions featuring a high level of instruction efficiency. With 1M bytes of address space, they are capable of executing instructions at high speed.

The M30201 group includes a wide range of products with different internal memory types and sizes and various package types.

# Features

- Basic machine instructions ...... Compatible with the M16C/60 series
- Memory capacity ...... ROM/RAM (See figure 1.4. ROM expansion.)
- Shortest instruction execution time ...... 100ns (f(XIN)=10MHz)
- - 2.7 to 5.5V (f(XIN)=3.5MHz ):mask ROM version
  - 4.0 to 5.5V (f(XIN)=10MHz) :flash memory version
- - (including key input interrupt)
- Multifunction 16-bit timer ...... Timer A x 1, timer B x 2, timer X x 3
- Clock output
- Serial I/O .....1 channel for UART or clock synchronous, 1 for UART
- A-D converter ...... 10 bits X 8 channels (Expandable up to 13 channels)
- Watchdog timer.....1 line
- Programmable I/O ......43 lines
- LED drive ports ......8 ports
- Clock generating circuit ......2 built-in clock generation circuits

(built-in feedback resistor, and external ceramic or quartz oscillator)

# Applications

Home appliances, Audio, office equipment, Automobiles

# -----Table of Contents-----

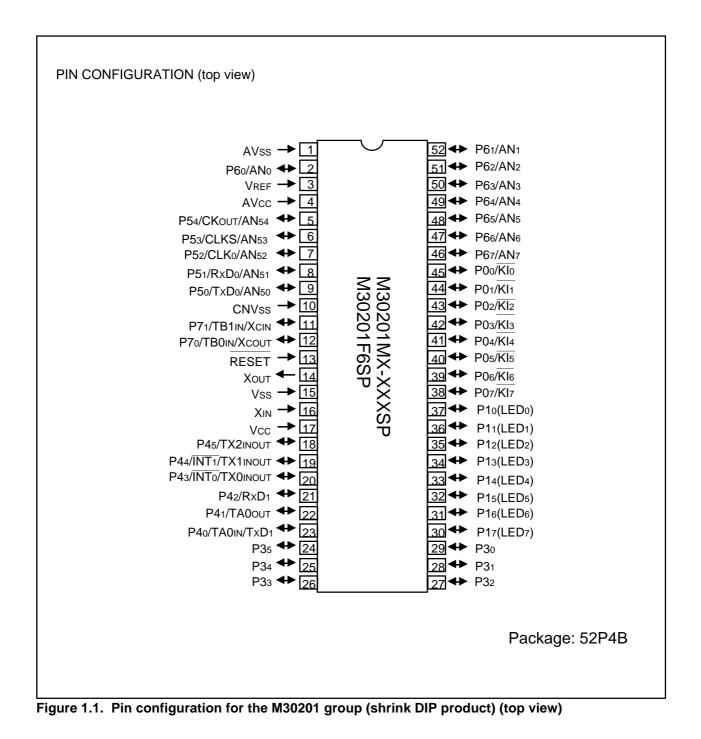

Central Processing Unit (CPU)	12
Reset	15
Clock Generating Circuit	19
Protection	26
Interrupts	27
Watchdog Timer	45

Timer	47
Serial I/O	74
A-D Converter	88
Programmable I/O Ports	
Electric Characteristics	110
Flash Memory version	124

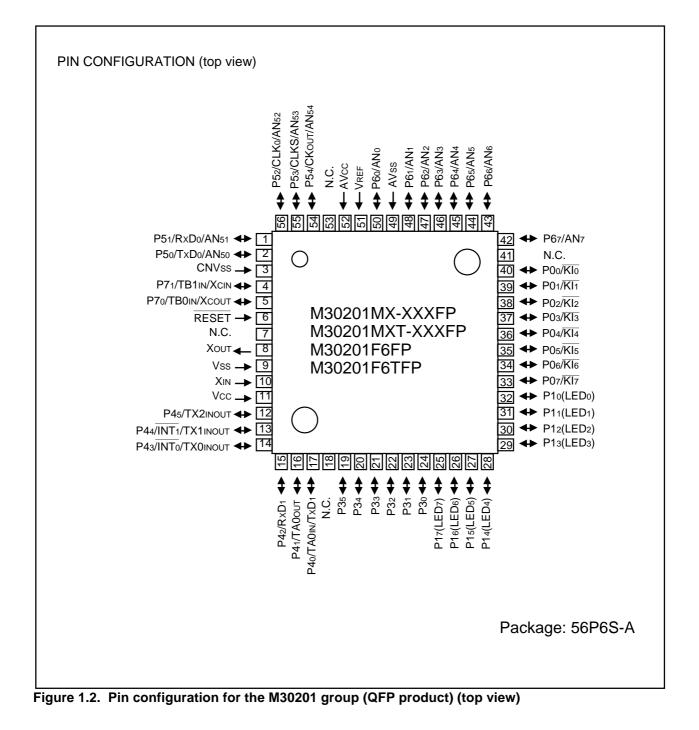

# **Pin Configuration**

Figures 1.1 to 1.2 show the pin configurations (top view).

# **Block Diagram**

Figure 1.3 is a block diagram of the M30201 group.

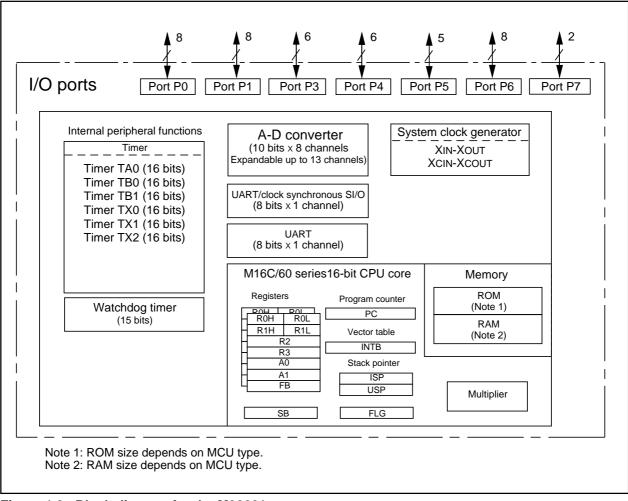

Figure 1.3. Block diagram for the M30201 group

# **Performance Outline**

Table 1.1 is performance outline of M30201 group.

Table 1.1. Performance outline of M30201 group

	Item	Performance		
Number of ba	sic instructions	91 instructions		
Shortest instru	uction execution time	100ns (f(XIN)=10MHz		
Memory	ROM	(See figure 4. ROM expansion.)		
capacity	RAM	(See figure 4. ROM expansion.)		
I/O port	P0 to P7	43 lines		
Multifunction	TA0	16 bits x 1		
timer	TB0, TB1	16 bits x 2		
	TX0, TX1, TX2	16 bits x 3		
Serial I/O	UART0	(UART or clock synchronous) x 1		
	UART1	UART x 1		
A-D converter		10 bits x 8 channels (Expandable up to 13 channels)		
Watchdog tim	er	15 bits x 1 (with prescaler)		
Interrupt		13 internal and 3 external sources, 4 software sources		
Clock generating circuit		2 built-in clock generation circuits		
		(built-in feedback resistor, and external ceramic or		
		quartz oscillator)		
Supply voltag	е	4.0 to 5.5V (f(XIN)=10MHz) :mask ROM version		
		2.7 to 5.5V (f(XIN)=3.5MHz) :mask ROM version		
		4.0 to 5.5V (f(XIN)=10MHz) :flash memory version		
Power consur	nption	11mW (f(XIN)=3.5MHz , Vcc=3V) :mask ROM version		
		95mW (f(XIN)=10MHz, Vcc=5V) :flash memory version		
I/O	I/O withstand voltage	5V		
characteristics	Output current	5mA (15mA:LED drive port)		
Device config	uration	CMOS silicon gate		
Package		52-pin plastic mold SDIP		
		56-pin plastic mold QFP		

Mitsubishi plans to release the following products in the M30201 group:

- (1) Support for mask ROM version and flash memory version
- (2) ROM capacity
- (3) Package
  - 52P4B : Plastic molded SDIP (mask ROM version and flash memory version)
  - 56P6S-A : Plastic molded QFP (mask ROM version and flash memory version)

#### **Pin Description**

Pin name	Signal name	I/O type	Function
Vcc, Vss	Power supply input		Supply 2.7 to 5.5 V to the Vcc pin. Supply 0 V to the Vss pin.
CNVss	CNVss	Input	Connect it to the Vss pin.
RESET	Reset input	Input	A "L" on this input resets the microcomputer.
Xin Xout	Clock input Clock output	Input Output	These pins are provided for the main clock generating circuit. Connect a ceramic resonator or crystal between the XIN and the XOUT pins. To use an externally derived clock, input it to the XIN pin and leave the XOUT pin open.
AVcc	Analog power supply input		This pin is a power supply input for the A-D converter. Connect it to Vcc.
AVss	Analog power supply input		This pin is a power supply input for the A-D converter. Connect it to Vss.
Vref	Reference voltage input	Input	This pin is a reference voltage input for the A-D converter.
P00 to P07	I/O port P0	Input/output	This is an 8-bit CMOS I/O port. It has an input/output port direction register that allows the user to set each pin for input or output individually. When set for input, the user can specify in units of four bits via software whether or not they are tied to a pull-up resistor.
P10 to P17	I/O port P1	Input/output	This is an 8-bit I/O port equivalent to P0.
P30 to P35	I/O port P3	Input/output	This is a 6-bit I/O port equivalent to P0.
P40 to P45	I/O port P4	Input/output	This is a 6-bit I/O port equivalent to P0. The P40 pin is shared with timer A0 input and serial I/O output TxD1. The P41 pin is shared with timer A0 output. The P42 pin is shared with serial I/O input RxD1. The P43 pin is shared with external interrupt INT0 and timer X0 input/output TX0INOUT. The P44 pin is shared with external interrupt INT1 and timer X1 input/output TX1INOUT. The P45 pin is shared with timer X2 input/output TX2INOUT.
P50 to P54	I/O port P5	Input/output	This is a 5-bit I/O port equivalent to P0. The P50, P51, P52, and P53 pins are shared with serial I/O pins TxD0, RxD0, CLK0, and CLKS. The P54 pin is shared with clock output CLKOUT. Also, these pins are shared with analog input pins AN50 through AN54.
P60 to P67	I/O port P6	Input/output	This is an 8-bit I/O port equivalent to P0. These pins are shared with analog input pins ANo through AN7.
P70 to P71	I/O port P7	Input/output	This is a 2-bit I/O port equivalent to P0 . These pins are used for input/output to and from the oscillator circuit for the clock. Connect a crystal oscillator between the XCIN and the XCOUT pins.

# **Operation of Functional Blocks**

The M30201 accommodates certain units in a single chip. These units include ROM and RAM to store instructions and data and the central processing unit (CPU) to execute arithmetic/logic operations. Also included are peripheral units such as timers, serial I/O, A-D converter, and I/O ports. The following explains each unit.

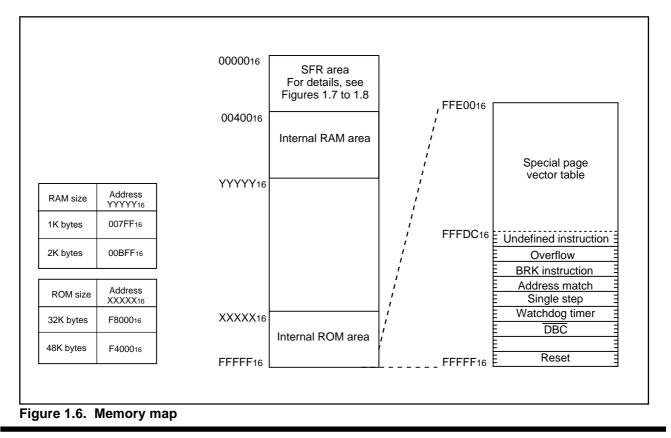

# Memory

Figure 1.6 is a memory map of the M30201. The address space extends the 1M bytes from address 0000016 to FFFF16. From FFFF16 down is ROM. For example, in the M30201M4-XXXSP, there is 32K bytes of internal ROM from F800016 to FFFF16. The vector table for fixed interrupts such as the reset are mapped to FFFDC16 to FFFF16. The starting address of the interrupt routine is stored here. The address of the vector table for timer interrupts, etc., can be set as desired using the internal register (INTB). See the section on interrupts for details.

From 0040016 up is RAM. For example, in the M30201M4-XXXSP, there is 1K byte of internal RAM from 0040016 to 007FF16. In addition to storing data, the RAM also stores the stack used when calling subroutines and when interrupts are generated.

The SFR area is mapped to 0000016 to 003FF16. This area accommodates the control registers for peripheral devices such as I/O ports, A-D converter, serial I/O, and timers, etc. Any part of the SFR area that is not occupied is reserved and cannot be used for other purposes.

The special page vector table is mapped to FFE0016 to FFFDB16. If the starting addresses of subroutines or the destination addresses of jumps are stored here, subroutine call instructions and jump instructions can be used as 2-byte instructions, reducing the number of program steps.

Figure 1.8. Location of peripheral unit control registers (2)

# Central Processing Unit (CPU)

The CPU has a total of 13 registers shown in Figure 1.9. Seven of these registers (R0, R1, R2, R3, A0, A1, and FB) come in two sets; therefore, these have two register banks.

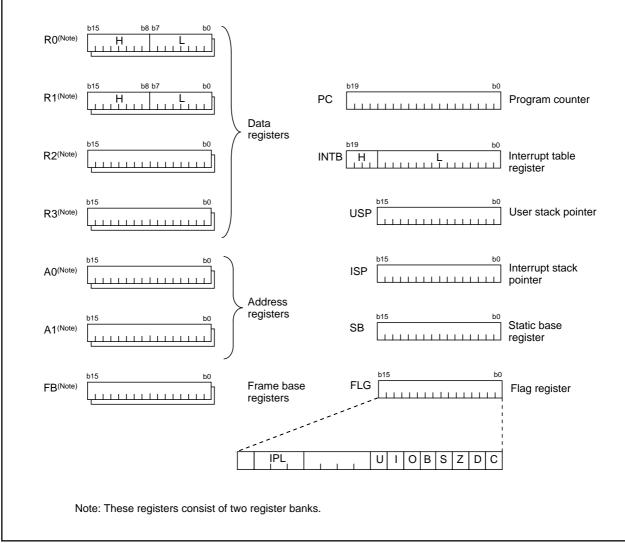

Figure 1.9. Central processing unit register

# (1) Data registers (R0, R0H, R0L, R1, R1H, R1L, R2, and R3)

Data registers (R0, R1, R2, and R3) are configured with 16 bits, and are used primarily for transfer and arithmetic/logic operations.

Registers R0 and R1 each can be used as separate 8-bit data registers, high-order bits as (R0H, R1H), and low-order bits as (R0L, R1L). In some instructions, registers R2 and R0, as well as R3 and R1 can use as 32-bit data registers (R2R0, R3R1).

# (2) Address registers (A0 and A1)

Address registers (A0 and A1) are configured with 16 bits, and have functions equivalent to those of data registers. These registers can also be used for address register indirect addressing and address register relative addressing.

In some instructions, registers A1 and A0 can be combined for use as a 32-bit address register (A1A0).

# CPU

# (3) Frame base register (FB)

Frame base register (FB) is configured with 16 bits, and is used for FB relative addressing.

# (4) Program counter (PC)

Program counter (PC) is configured with 20 bits, indicating the address of an instruction to be executed.

# (5) Interrupt table register (INTB)

Interrupt table register (INTB) is configured with 20 bits, indicating the start address of an interrupt vector table.

# (6) Stack pointer (USP/ISP)

Stack pointer comes in two types: user stack pointer (USP) and interrupt stack pointer (ISP), each configured with 16 bits.

Your desired type of stack pointer (USP or ISP) can be selected by a stack pointer select flag (U flag). This flag is located at the position of bit 7 in the flag register (FLG).

# (7) Static base register (SB)

Static base register (SB) is configured with 16 bits, and is used for SB relative addressing.

# (8) Flag register (FLG)

Flag register (FLG) is configured with 11 bits, each bit is used as a flag. Figure 1.10 shows the flag register (FLG). The following explains the function of each flag:

# • Bit 0: Carry flag (C flag)

This flag retains a carry, borrow, or shift-out bit that has occurred in the arithmetic/logic unit.

# • Bit 1: Debug flag (D flag)

This flag enables a single-step interrupt.

When this flag is "1", a single-step interrupt is generated after instruction execution. This flag is cleared to "0" when the interrupt is acknowledged.

# • Bit 2: Zero flag (Z flag)

This flag is set to "1" when an arithmetic operation resulted in 0; otherwise, cleared to "0".

# • Bit 3: Sign flag (S flag)

This flag is set to "1" when an arithmetic operation resulted in a negative value; otherwise, cleared to "0".

# • Bit 4: Register bank select flag (B flag)

This flag chooses a register bank. Register bank 0 is selected when this flag is "0"; register bank 1 is selected when this flag is "1".

# • Bit 5: Overflow flag (O flag)

This flag is set to "1" when an arithmetic operation resulted in overflow; otherwise, cleared to "0".

# Bit 6: Interrupt enable flag (I flag)

This flag enables a maskable interrupt.

An interrupt is disabled when this flag is "0", and is enabled when this flag is "1". This flag is cleared to "0" when the interrupt is acknowledged.

# CPU

#### • Bit 7: Stack pointer select flag (U flag)

Interrupt stack pointer (ISP) is selected when this flag is "0"; user stack pointer (USP) is selected when this flag is "1".

This flag is cleared to "0" when a hardware interrupt is acknowledged or an INT instruction of software interrupt Nos. 0 to 31 is executed.

#### • Bits 8 to 11: Reserved area

• Bits 12 to 14: Processor interrupt priority level (IPL)

Processor interrupt priority level (IPL) is configured with three bits, for specification of up to eight processor interrupt priority levels from level 0 to level 7.

If a requested interrupt has priority greater than the processor interrupt priority level (IPL), the interrupt is enabled.

#### • Bit 15: Reserved area

The C, Z, S, and O flags are changed when instructions are executed. See the software manual for details.

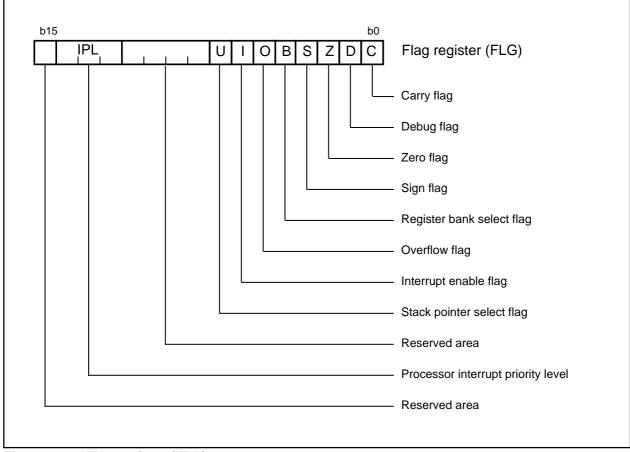

Figure 1.10. Flag register (FLG)

# Reset

There are two kinds of resets; hardware and software. In both cases, operation is the same after the reset. (See "Software Reset" for details of software resets.) This section explains on hardware resets.

When the supply voltage is in the range where operation is guaranteed, a reset is effected by holding the reset pin level "L" (0.2Vcc max.) for at least 20 cycles. When the reset pin level is then returned to the "H" level while main clock is stable, the reset status is cancelled and program execution resumes from the address in the reset vector table.

Figure 1.11 shows the example reset circuit. Figure 1.12 shows the reset sequence.

x : Nothing is mapped to this bit ? : Undefined

The content of other registers and RAM is undefined when the microcomputer is reset. The initial values must therefore be set.

Note: This register is only exist in flash memory version.

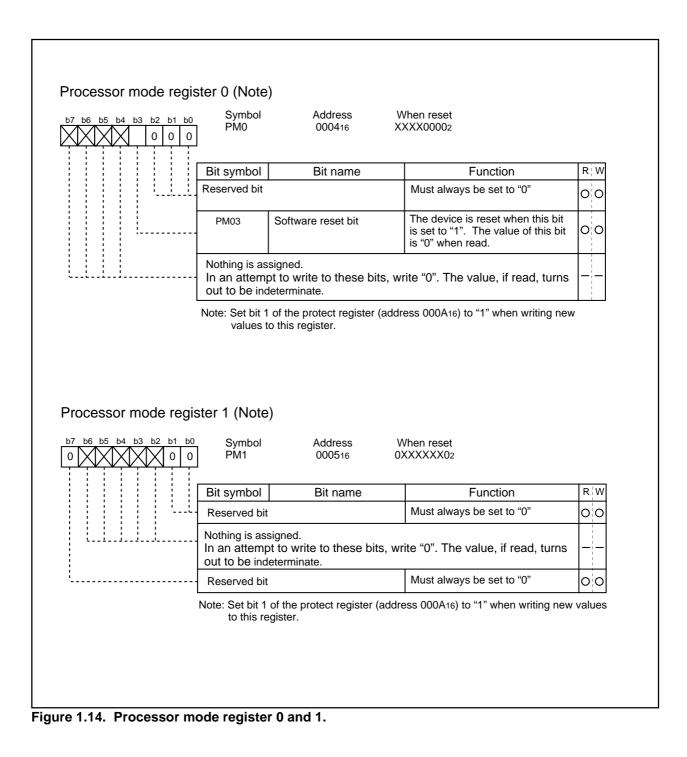

#### Figure 1.13. Device's internal status after a reset is cleared

# **Software Reset**

Writing "1" to bit 3 of the processor mode register 0 (address 000416) applies a (software) reset to the microcomputer. A software reset has almost the same effect as a hardware reset. The contents of internal RAM are preserved.

Figure 1.14 shows the processor mode register 0 and 1.

# **Clock Generating Circuit**

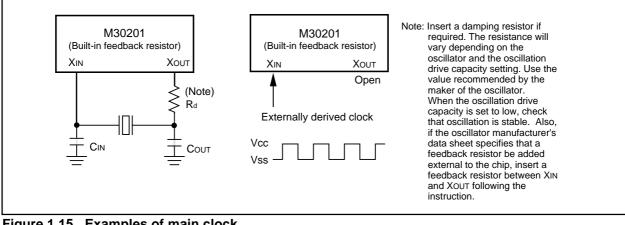

The clock generating circuit contains two oscillator circuits that supply the operating clock sources to the CPU and internal peripheral units.

Table 1.2. Main clock and sub-clock generating circuits

	Main clock generating circuit	Sub clock generating circuit	
Use of clock	CPU's operating clock source	CPU's operating clock source	
	<ul> <li>Internal peripheral units'</li> </ul>	Timer A/B/X's count clock	
	operating clock source	source	
Usable oscillator	Ceramic or crystal oscillator	Crystal oscillator	
Pins to connect oscillator	Xin, Xout	XCIN, XCOUT	
Oscillation stop/restart function	Available	Available	
Oscillator status immediately after reset	Oscillating	Stopped	
Other	Externally derived clock can be input		

# Example of oscillator circuit

Figure 1.15 shows some examples of the main clock circuit, one using an oscillator connected to the circuit, and the other one using an externally derived clock for input. Figure 1.16 shows some examples of subclock circuits, one using an oscillator connected to the circuit, and the other one using an externally derived clock for input. Circuit constants in Figures 15 and 16 vary with each oscillator used. Use the values recommended by the manufacturer of your oscillator.

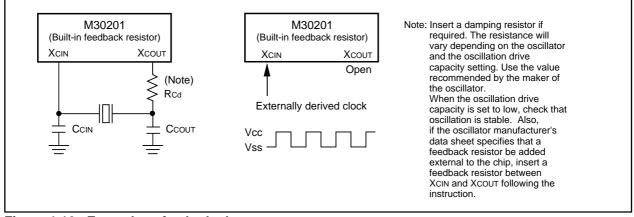

Figure 1.16. Examples of sub-clock

# **Clock Generating Circuit**

# **Clock Control**

Figure 1.17 shows the block diagram of the clock generating circuit.

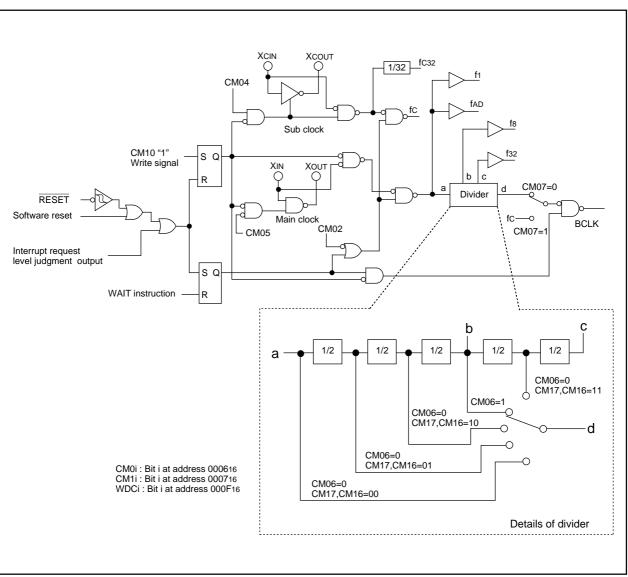

Figure 1.17. Clock generating circuit

The following paragraphs describes the clocks generated by the clock generating circuit.

# (1) Main clock

The main clock is generated by the main clock oscillation circuit. After a reset, the clock is divided by 8 to BCLK. The clock can be stopped using the main clock stop bit (bit 5 at address 000616). Stopping the clock, after switching the operating clock source of CPU to the sub-clock, reduces the power dissipation. After the oscillation of the main clock oscillation circuit has stabilized, the drive capacity of the main clock oscillation circuit can be reduced using the XIN-XOUT drive capacity select bit (bit 5 at address 000716). Reducing the drive capacity of the main clock oscillation circuit reduces the power dissipation. This bit changes to "1" when shifting from high-speed/medium-speed mode to stop mode and at a reset. When shifting from low-speed/low power dissipation mode to stop mode, the value before stop mode is retained.

# (2) Sub-clock

The sub-clock is generated by the sub-clock oscillation circuit. No sub-clock is generated after a reset. After oscillation is started using the port Xc select bit (bit 4 at address 0006<sub>16</sub>), the sub-clock can be selected as BCLK by using the system clock select bit (bit 7 at address 0006<sub>16</sub>). However, be sure that the sub-clock oscillation has fully stabilized before switching.

After the oscillation of the sub-clock oscillation circuit has stabilized, the drive capacity of the sub-clock oscillation circuit can be reduced using the XCIN-XCOUT drive capacity select bit (bit 3 at address 000616). Reducing the drive capacity of the sub-clock oscillation circuit reduces the power dissipation. This bit changes to "1" when shifting to stop mode and at a reset.

# (3) BCLK

The BCLK is the clock that drives the CPU, and is fc or the clock is derived by dividing the main clock by 1, 2, 4, 8, or 16. The BCLK is derived by dividing the main clock by 8 after a reset.

The main clock division select bit 0(bit 6 at address 000616) changes to "1" when shifting from high-speed/medium-speed to stop mode and at reset. When shifting from low-speed/low power dissipation mode to stop mode, the value before stop mode is retained.

# (4) Peripheral function clock (f1, f8, f32, fAD)

The clock for the peripheral devices is derived from the main clock or by dividing it by 8 or 32. The peripheral function clock is stopped by stopping the main clock or by setting the WAIT peripheral function clock stop bit (bit 2 at 000616) to "1" and then executing a WAIT instruction.

# (5) fC32

This clock is derived by dividing the sub-clock by 32. It is used for the timer A, timer B and timer X counts.

# (6) fC

This clock has the same frequency as the sub-clock. It is used for BCLK and for the watchdog timer.

Figure 1.18 shows the system clock control registers 0 and 1.

Figure 1.18. Clock control registers 0 and 1

# **Clock Generating Circuit**

# **Clock Output**

The clock output function select bit allows you to choose the clock from f8, fc, or a divide-by-n clock that is output from the P54/CKOUT pin. The clock divide counter is an 8-bit counter whose count source is f32, and its divide ratio can be set in the range of 0016 to FF16. Figure 1.19 shows a block diagram of clock output.

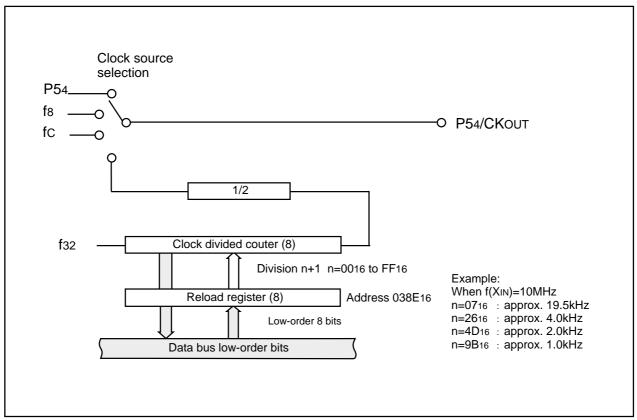

Figure 1.19. Block diagram of clock output

# Stop Mode

Writing "1" to the all-clock stop control bit (bit 0 at address 000716) stops all oscillation and the microcomputer enters stop mode. In stop mode, the content of the internal RAM is retained provided that VCC remains above 2V.

Because the oscillation of BCLK, f1 to f32, fc, fc32, and fAD stops in stop mode, peripheral functions such as the A-D converter and watchdog timer do not function. However, timer A, timer B and timer X operate provided that the event counter mode is set to an external pulse, and UART0 functions provided an external clock is selected. Table 1.3 shows the status of the ports in stop mode.

Stop mode is cancelled by a hardware reset or an interrupt. If an interrupt is to be used to cancel stop mode, that interrupt must first have been enabled. If returning by an interrupt, that interrupt routine is executed.

When shifting from high-speed/medium-speed mode to stop mode and at a reset, the main clock division select bit 0 (bit 6 at address 000616) is set to "1". When shifting from low-speed/low power dissipation mode to stop mode, the value before stop mode is retained.

	Pin	States
Port		Retains status before stop mode
CLKOUT	When fC selected	"H"
	When f8, clock devided counter output selected	Retains status before stop mode

#### Table 1.3. Port status during stop mode

# Wait Mode

When a WAIT instruction is executed, BCLK stops and the microcomputer enters the wait mode. In this mode, oscillation continues but BCLK and watchdog timer stop. Writing "1" to the WAIT peripheral function clock stop bit and executing a WAIT instruction stops the clock being supplied to the internal peripheral functions, allowing power dissipation to be reduced. However, peripheral function clock fC32 does not stop so that the peripherals using fC32 do not contribute to the power saving. When the MCU running in low-speed or low power dissipation mode, do not enter WAIT mode with this bit set to "1". Table 1.4 shows the status of the ports in wait mode.

Wait mode is cancelled by a hardware reset or interrupt. If an interrupt is used to cancel wait mode, the microcomputer restarts from the interrupt routine using as BCLK, the clock that had been selected when the WAIT instruction was executed.

	Pin	States
Port		Retains status before wait mode
CLKOUT	When fc selected	Does not stop
	When f8, clock devided counter output selected	Does not stop when the WAIT peripheral function clock stop bit is "0". When the WAIT peripheral function clock stop bit is "1",the status immedi- ately prior to entering wait mode is maintained.

#### Table 1.4. Port status during wait mode

# **Status Transition of BCLK**

Power dissipation can be reduced and low-voltage operation achieved by changing the count source for BCLK. Table 1.5 shows the operating modes corresponding to the settings of system clock control registers 0 and 1.

When reset, the device starts in division by 8 mode. The main clock division select bit 0(bit 6 at address 000616) changes to "1" when shifting from high-speed/medium-speed to stop mode and at a reset. When shifting from low-speed/low power dissipation mode to stop mode, the value before stop mode is retained. The following shows the operational modes of BCLK.

# (1) Division by 2 mode

The main clock is divided by 2 to obtain the BCLK.

#### (2) Division by 4 mode

The main clock is divided by 4 to obtain the BCLK.

#### (3) Division by 8 mode

The main clock is divided by 8 to obtain the BCLK. When reset, the device starts operating from this mode. Before the user can go from this mode to no division mode, division by 2 mode, or division by 4 mode, the main clock must be oscillating stably. When going to low-speed or lower power consumption mode, make sure the sub-clock is oscillating stably.

#### (4) Division by 16 mode

The main clock is divided by 16 to obtain the BCLK.

#### (5) No-division mode

The main clock is divided by 1 to obtain the BCLK.

#### (6) Low-speed mode

fc is used as BCLK. Note that oscillation of both the main and sub-clocks must have stabilized before transferring from this mode to another or vice versa. At least 2 to 3 seconds are required after the sub-clock starts. Therefore, the program must be written to wait until this clock has stabilized immediately after powering up and after stop mode is cancelled.

#### (7) Low power dissipation mode

fc is the BCLK and the main clock is stopped.

Note : Before the count source for BCLK can be changed from XIN to XCIN or vice versa, the clock to which the count source is going to be switched must be oscillating stably. Allow a wait time in software for the oscillation to stabilize before switching over the clock.

				J		<b>, ,</b>
CM17	CM16	CM07	CM06	CM05	CM04	Operating mode of BCLK
0	1	0	0	0	Invalid	Division by 2 mode

Invalid	Invalid	1	Invalid	1	1	Low power dissipation mode

Table 1.5. Operating modes dictated by settings of system clock control registers 0 and 1

# **Power Saving**

There are three power save modes.

# (1) Normal operating mode

#### • High-speed mode

In this mode, one main clock cycle forms BCLK. The CPU operates on the BCLK. The peripheral functions operate on the clocks specified for each respective function.

#### • Medium-speed mode

In this mode, the main clock is divided into 2, 4, 8, or 16 to form BCLK. The CPU operates on the BCLK. The peripheral functions operated on the clocks specified for each respective function.

#### • Low-speed mode

In this mode, fc forms BCLK. The CPU operates on the fc clock. fc is the clock supplied by the subclock. The peripheral functions operate on the clocks specified for each respective function.

#### • Low power-dissipation mode

This mode is selected when the main clock is stopped from low-speed mode. The CPU operates on the fc clock. fc is the clock supplied by the subclock. Only the peripheral functions for which the subclock was selected as the count source continue to run.

# (2) Wait mode

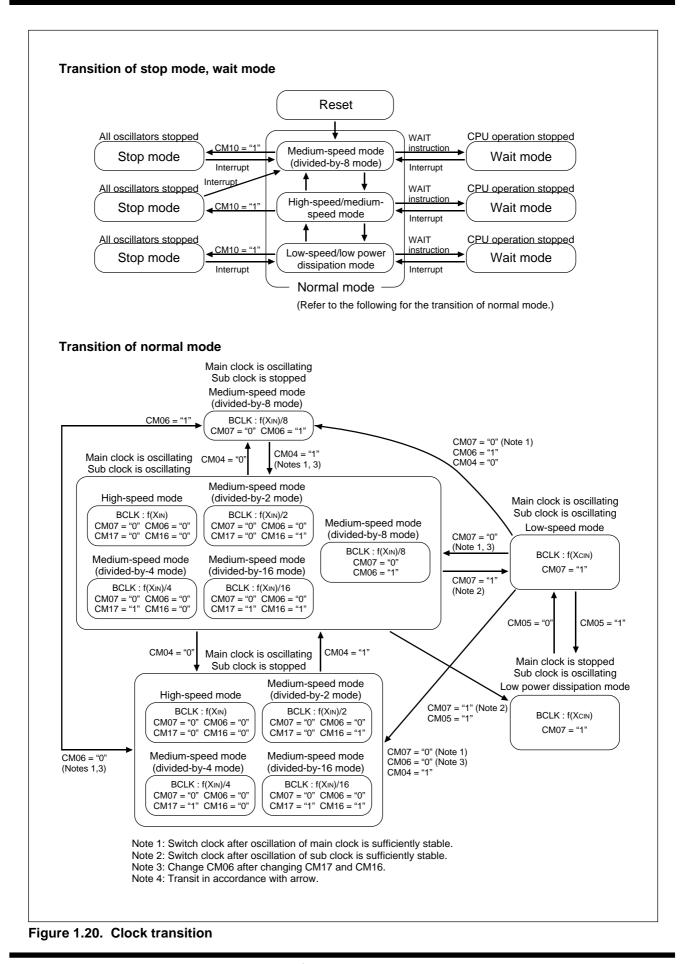

CPU operation is halted in this mode. The oscillator continues to run.

# (3) Stop mode

All oscillators stop in this mode. The CPU and internal peripheral functions all stop. Of all 3 power saving modes, power savings are greatest in this mode.

Figure 1.20 shows the transition between each of the three modes, (1), (2), and (3).

# Protection

The protection function is provided so that the values in important registers cannot be changed in the event that the program runs out of control. Figure 1.21 shows the protect register. The values in the processor mode register 0 (address 000416), processor mode register 1 (address 000516), system clock control register 0 (address 000616), system clock control register 1 (address 000716) and port P4 direction register (address 03EA16) can only be changed when the respective bit in the protect register is set to "1". Therefore, important outputs can be allocated to port P4.

If, after "1" (write-enabled) has been written to the port P4 direction register write-enable bit (bit 2 at address 000A16), a value is written to any address, the bit automatically reverts to "0" (write-inhibited). However, the system clock control registers 0 and 1 write-enable bit (bit 0 at 000A16) and processor mode register 0 and 1 write-enable bit (bit 1 at 000A16) do not automatically return to "0" after a value has been written to an address. The program must therefore be written to return these bits to "0".

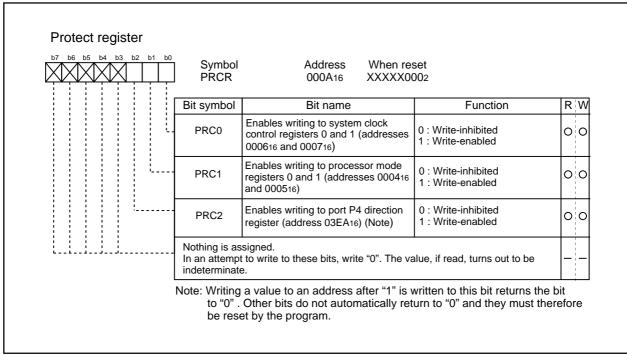

Figure 1.21. Protect register

# **Overview of Interrupt**

# **Type of Interrupts**

Figure 1.22 lists the types of interrupts.

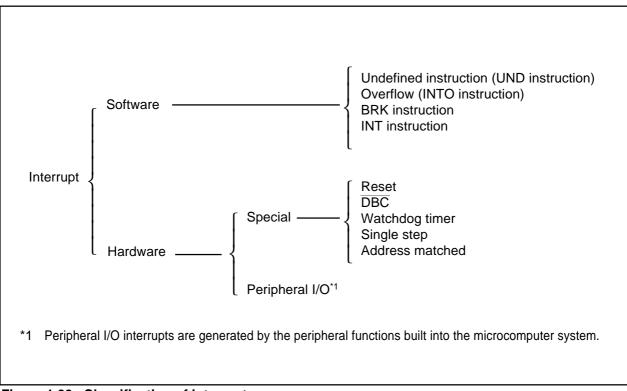

Figure 1.22. Classification of interrupts

<ul> <li>Maskable interrupt</li> </ul>	: An interrupt which can be enabled (disabled) by the interrupt enable flag (I
	flag) or whose interrupt priority can be changed by priority level.
<ul> <li>Non-maskable interrupt</li> </ul>	: An interrupt which cannot be enabled (disabled) by the interrupt enable flag
	(I flag) or whose interrupt priority cannot be changed by priority level.

## **Software Interrupts**

A software interrupt occurs when executing certain instructions. Software interrupts are non-maskable interrupts.

# Undefined instruction interrupt

An undefined instruction interrupt occurs when executing the UND instruction.

#### Overflow interrupt

An overflow interrupt occurs when executing the INTO instruction with the overflow flag (O flag) set to "1". The following are instructions whose O flag changes by arithmetic:

ABS, ADC, ADCF, ADD, CMP, DIV, DIVU, DIVX, NEG, RMPA, SBB, SHA, SUB

#### BRK interrupt

A BRK interrupt occurs when executing the BRK instruction.

#### • INT interrupt

An INT interrupt occurs when assigning one of software interrupt numbers 0 through 63 and executing the INT instruction. Software interrupt numbers 0 through 31 are assigned to peripheral I/O interrupts, so executing the INT instruction allows executing the same interrupt routine that a peripheral I/O interrupt does.

The stack pointer (SP) used for the INT interrupt is dependent on which software interrupt number is involved.

So far as software interrupt numbers 0 through 31 are concerned, the microcomputer saves the stack pointer assignment flag (U flag) when it accepts an interrupt request. If change the U flag to "0" and select the interrupt stack pointer (ISP), and then execute an interrupt sequence. When returning from the interrupt routine, the U flag is returned to the state it was before the acceptance of interrupt request. So far as software numbers 32 through 63 are concerned, the stack pointer does not make a shift.

#### **Hardware Interrupts**

Hardware interrupts are classified into two types - special interrupts and peripheral I/O interrupts.

### (1) Special interrupts

Special interrupts are non-maskable interrupts.

Reset

Reset occurs if an "L" is input to the RESET pin.

• DBC interrupt

This interrupt is exclusively for the debugger, do not use it in other circumstances.

Watchdog timer interrupt

Generated by the watchdog timer.

• Single-step interrupt

This interrupt is exclusively for the debugger, do not use it in other circumstances. With the debug flag (D flag) set to "1", a single-step interrupt occurs after one instruction is executed.

Address match interrupt

An address match interrupt occurs immediately before the instruction held in the address indicated by the address match interrupt register is executed with the address match interrupt enable bit set to "1". If an address other than the first address of the instruction in the address match interrupt register is set, no address match interrupt occurs.

# (2) Peripheral I/O interrupts

A peripheral I/O interrupt is generated by one of built-in peripheral functions. The interrupt vector table is the same as the one for software interrupt numbers 0 through 31 the INT instruction uses. Peripheral I/O interrupts are maskable interrupts.

• Key-input interrupt

A key-input interrupt occurs if an "L" is input to the  $\overline{\text{KI}}$  pin.

• A-D conversion interrupt

This is an interrupt that the A-D converter generates.

• UART0 and UART1 transmission interrupt

These are interrupts that the serial I/O transmission generates.

• UART0 and UART1 reception interrupt

These are interrupts that the serial I/O reception generates.

• Timer A0 interrupt

This is an interrupts that timer A0 generates.

• Timer B0 and timer B2 interrupt

These are interrupts that timer B generates.

• Timer X0 to timer X2 interrupt

These are interrupts that timer X generates.

• INTO and INT1 interrupt

An INT interrupt occurs if either a rising edge or a falling edge is input to the INT pin.

# Interrupts and Interrupt Vector Tables

If an interrupt request is accepted, a program branches to the interrupt routine set in the interrupt vector table. Set the first address of the interrupt routine in each vector table. Figure 1.23 shows format for specifying interrupt vector addresses.

Two types of interrupt vector tables are available — fixed vector table in which addresses are fixed and variable vector table in which addresses can be varied by the setting.

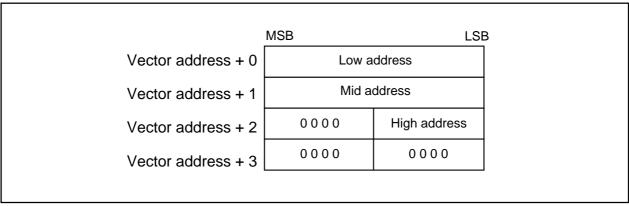

Figure 1.23. Format for specifying interrupt vector addresses

### Fixed vector tables

The fixed vector table is a table in which addresses are fixed. The vector tables are located in an area extending from FFFDC16 to FFFF16. One vector table comprises four bytes. Set the first address of interrupt routine in each vector table. Table 1.6 shows the interrupts assigned to the fixed vector tables and addresses of vector tables.

Interrupt source	Vector table addresses	Remarks
	Address (L) to address (H)	
Undefined instruction	FFFDC16 to FFFDF16	Interrupt on UND instruction
Overflow	FFFE016 to FFFE316	Interrupt on INTO instruction
BRK instruction	FFFE416 to FFFE716	If the vector is filled with FF16, program execution starts from
		the address shown by the vector in the variable vector table
Address match	FFFE816 to FFFEB16	There is an address-matching interrupt enable bit
Single step (Note)	FFFEC16 to FFFEF16	Do not use
Watchdog timer	FFFF016 to FFFF316	
DBC (Note)	FFFF416 to FFFF716	Do not use
-	FFFF816 to FFFFB16	-
Reset	FFFFC16 to FFFFF16	

Table 1.6. Interrupt and fixed vector address

Note: Interrupts used for debugging purposes only.

# • Variable vector tables

The addresses in the variable vector table can be modified, according to the user's settings. Indicate the first address using the interrupt table register (INTB). The 256-byte area subsequent to the address the INTB indicates becomes the area for the variable vector tables. One vector table comprises four bytes. Set the first address of the interrupt routine in each vector table. Table 1.7 shows the interrupts assigned to the variable vector tables and addresses of vector tables.

Software interrupt number	Vector table address Address (L) to address (H)	Interrupt source	Remarks
Software interrupt number 0	+0 to +3 (Note)	BRK instruction	Cannot be masked by I flag
Software interrupt number 11	+44 to +47 (Note)		
Software interrupt number 12	+48 to +51 (Note)		
Software interrupt number 13	+52 to +55 (Note)	Key input interrupt	
Software interrupt number 14	+56 to +59 (Note)	A-D	
Software interrupt number 17	+68 to +71 (Note)	UART0 transmit	
Software interrupt number 18	+72 to +75 (Note)	UART0 receive	
Software interrupt number 19	+76 to +79 (Note)	UART1 transmit	
Software interrupt number 20	+80 to +83 (Note)	UART1 receive	
Software interrupt number 21	+84 to +87 (Note)	Timer A0	
Software interrupt number 22	+88 to +91 (Note)	Timer X0	
Software interrupt number 23	+92 to +95 (Note)	Timer X1	
Software interrupt number 24	+96 to +99 (Note)	Timer X2	
Software interrupt number 25	+100 to +103 (Note)		
Software interrupt number 26	+104 to +107 (Note)	Timer B0	
Software interrupt number 27	+108 to +111 (Note)	Timer B1	
Software interrupt number 28	+112 to +115 (Note)		
Software interrupt number 29	+116 to +119 (Note)	INT0	
Software interrupt number 30	+120 to +123 (Note)	INT1	
Software interrupt number 31	+124 to +127 (Note)		
Software interrupt number 32	+128 to +131 (Note)		
to Software interrupt number 63	to +252 to +255 (Note)	Software interrupt	Cannot be masked by I flag

Note : Address relative to address in interrupt table register (INTB).

# **Interrupt Control**

Descriptions are given here regarding how to enable or disable maskable interrupts and how to set the priority to be accepted. What is described here does not apply to non-maskable interrupts.

Enable or disable a maskable interrupt using the interrupt enable flag (I flag), interrupt priority level select bit, and processor interrupt priority level (IPL). Whether an interrupt request is present or absent is indicated by the interrupt request bit. The interrupt request bit and the interrupt priority level selection bit are located in the interrupt control register of each interrupt. Also, the interrupt enable flag (I flag) and the IPL are located in the flag register (FLG).

Figure 1.24 shows the interrupt control registers.

Figure 1.24. Interrupt control register

# Interrupt Enable Flag

The interrupt enable flag (I flag) controls the enabling and disabling of maskable interrupts. Setting this flag to "1" enables all maskable interrupts; setting it to "0" disables all maskable interrupts. This flag is set to "0" after reset.

# **Interrupt Request Bit**

The interrupt request bit is set to "1" by hardware when an interrupt is requested. After the interrupt is accepted and jumps to the corresponding interrupt vector, the request bit is set to "0" by hardware. The interrupt request bit can also be set to "0" by software. (Do not set this bit to "1").

# Interrupt Priority Level Select Bit and Processor Interrupt Priority Level (IPL)

Set the interrupt priority level using the interrupt priority level select bit, which is one of the component bits of the interrupt control register. When an interrupt request occurs, the interrupt priority level is compared with the IPL. The interrupt is enabled only when the priority level of the interrupt is higher than the IPL. Therefore, setting the interrupt priority level to "0" disables the interrupt.

Table 1.8 shows the settings of interrupt priority levels and Table 1.9 shows the interrupt levels enabled, according to the contents of the IPL.

The following are conditions under which an interrupt is accepted:

- interrupt enable flag (I flag) = 1
- interrupt request bit = 1
- interrupt priority level > IPL

The interrupt enable flag (I flag), the interrupt request bit, the interrupt priority select bit, and the IPL are independent, and they are not affected by one another.

#### Table 1.8. Settings of interrupt priority levels

		oriority ect bit	Interrupt priority level	Priority order
b2 0	b1 0	ь0 О	Level 0 (interrupt disabled)

Interrupts

# **Changing the Interrupt Control Register**

#### < Program examples >

The program examples are described as follow:

Exam IN	ple 1: T_SWITCF	11:	
	FCLR	I	; Disable interrupts.
	AND.B	#00h, 0055h	; Clear TA0IC int. priority level and int. request bit.
	NOP		; Four NOP instructions are required when using HOLD function.
	NOP		
	FSET	I	; Enable interrupts.
Exam	ple 2:		
IN	T_SWITCH	12:	
	FCLR	I	; Disable interrupts.
	AND.B	#00h, 0055h	; Clear TA0IC int. priority level and int. request bit.
	MOV.W	MEM, R0	; Dummy read.
	FSET	I	; Enable interrupts.
Exam	-		
IN	T_SWITCH	13:	
	PUSHC	FLG	; Push Flag register onto stack
	FCLR	I	; Disable interrupts.
	AND.B	#00h, 0055h	; Clear TA0IC int. priority level and int. request bit.
	POPC	FLG	; Enable interrupts.

The reason why two NOP instructions or dummy read are inserted before FSET I in Examples 1 and 2 is to prevent the interrupt enable flag I from being set before the interrupt control register is rewritten due to effects of the instruction queue.

If changing the interrupt control register using an instruction other than the instructions listed hear, and if an interrupt occurs associated with this register during execution of the instruction, there can be instances in which the interrupt request bit is not set. To avoid this problem, use one of the instructions given below to change the register.

Following instructions: AND, OR, BCLR or BSET

### **Interrupt Sequence**

An interrupt sequence — what are performed over a period from the instant an interrupt is accepted to the instant the interrupt routine is executed — is described here.

If an interrupt occurs during execution of an instruction, the processor determines its priority when the execution of the instruction is completed, and transfers control to the interrupt sequence from the next cycle. If an interrupt occurs during execution of either the SMOVB, SMOVF, SSTR or RMPA instruction, the processor temporarily suspends the instruction being executed, and transfers control to the interrupt sequence.

In the interrupt sequence, the processor carries out the following in sequence given:

- (1) CPU gets the interrupt information (the interrupt number and interrupt request level) by reading address 0000016. After this, the corresponding interrupt request bit becomes "0".
- (2) Saves the content of the flag register (FLG) as it was immediately before the start of interrupt sequence in the temporary register (Note) within the CPU.
- (3) Sets the interrupt enable flag (I flag), the debug flag (D flag), and the stack pointer select flag (U flag) to "0" (the U flag, however, does not change if the INT instruction, in software interrupt numbers 32 through 63, is executed).
- (4) Saves the content of the temporary register (Note) within the CPU in the stack area.
- (5) Saves the content of the program counter (PC) in the stack area.
- (6) Sets the interrupt priority level of the accepted instruction in the IPL.

After the interrupt sequence is completed, the processor resumes executing instructions from the first address of the interrupt routine.

Note: This register cannot be utilized by the user.

# Interrupt Response Time

'Interrupt response time' is the period between the instant an interrupt occurs and the instant the first instruction within the interrupt routine has been executed. This time comprises the period from the occurrence of an interrupt to the completion of the instruction under execution at that moment (a) and the time required for executing the interrupt sequence (b). Figure 1.25 shows the interrupt response time.

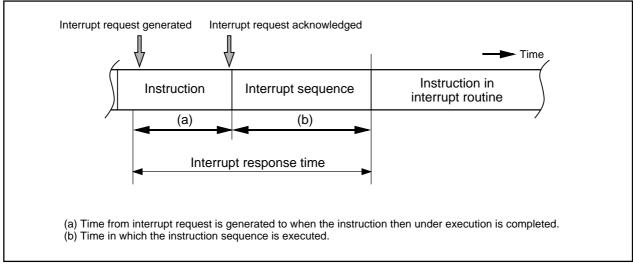

Figure 1.25. Interrupt response time

Time (a) is dependent on the instruction under execution. Thirty cycles is the maximum required for the DIVX instruction (without wait).

Time (b) is as shown in Table 1.10.

Table 1.10. Time requ	incu for excedding the in	ch upt sequence		
Interrupt vector address	Stack pointer (SP) value	16-bit bus, without wait	8-bit bus, without wait	
Even	Even	18 cycles (Note 1)	20 cycles (Note 1)	
Even	Odd	19 cycles (Note 1)	20 cycles (Note 1)	
Odd (Note 2)	Even	19 cycles (Note 1)	20 cycles (Note 1)	
Odd (Note 2)	Odd	20 cycles (Note 1)	20 cycles (Note 1)	

Table 1.10. Time required for executing the interrupt sequence

Note 1: Add 2 cycles in the case of a DBC interrupt; add 1 cycle in the case either of an address match interrupt or of a single-step interrupt.

Note 2: Locate an interrupt vector address in an even address, if possible.

BCLK	
Address bus	Address 000016 Indeterminate SP-2 SP-4 vec vec+2 PC
Data bus	Interrupt Indeterminate SP-2 SP-4 vec vec+2 contents
R	
W	
	The indeterminate segment is dependent on the queue buffer. If the queue buffer is ready to take an instruction, a read cycle occurs.

Figure 1.26. Time required for executing the interrupt sequence

#### Variation of IPL when Interrupt Request is Accepted

If an interrupt request is accepted, the interrupt priority level of the accepted interrupt is set in the IPL. If an interrupt request, that does not have an interrupt priority level, is accepted, one of the values shown in Table 1.11 is set in the IPL.

Interrupt sources without priority levels	Value set in the IPL
Watchdog timer	7
Reset	0
Other	Not changed

### **Saving Registers**

In the interrupt sequence, only the contents of the flag register (FLG) and that of the program counter (PC) are saved in the stack area.

First, the processor saves the 4 high-order bits of the program counter, and 4 high-order bits and 8 loworder bits of the FLG register, 16 bits in total, in the stack area, then saves 16 low-order bits of the program counter. Figure 1.27 shows the state of the stack as it was before the acceptance of the interrupt request, and the state the stack after the acceptance of the interrupt request.

Save other necessary registers at the beginning of the interrupt routine using software. Using the PUSHM instruction alone can save all the registers except the stack pointer (SP).

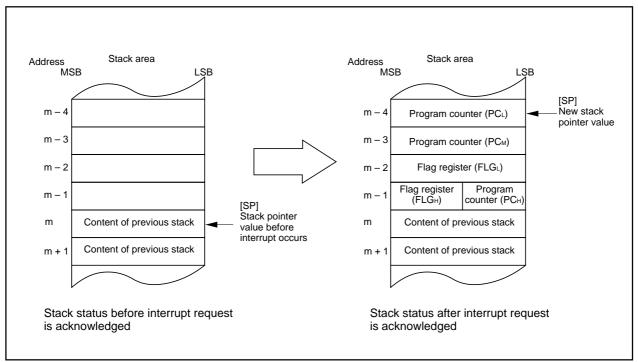

Figure 1.27. State of stack before and after acceptance of interrupt request

The operation of saving registers carried out in the interrupt sequence is dependent on whether the content of the stack pointer (Note), at the time of acceptance of an interrupt request, is even or odd. If the content of the stack pointer (Note) is even, the content of the flag register (FLG) and the content of the program counter (PC) are saved, 16 bits at a time. If odd, their contents are saved in two steps, 8 bits at a time. Figure 1.28 shows the operation of the saving registers.

Note: When any INT instruction in software numbers 32 to 63 has been executed, this is the stack pointer indicated by the U flag. Otherwise, it is the interrupt stack pointer (ISP).

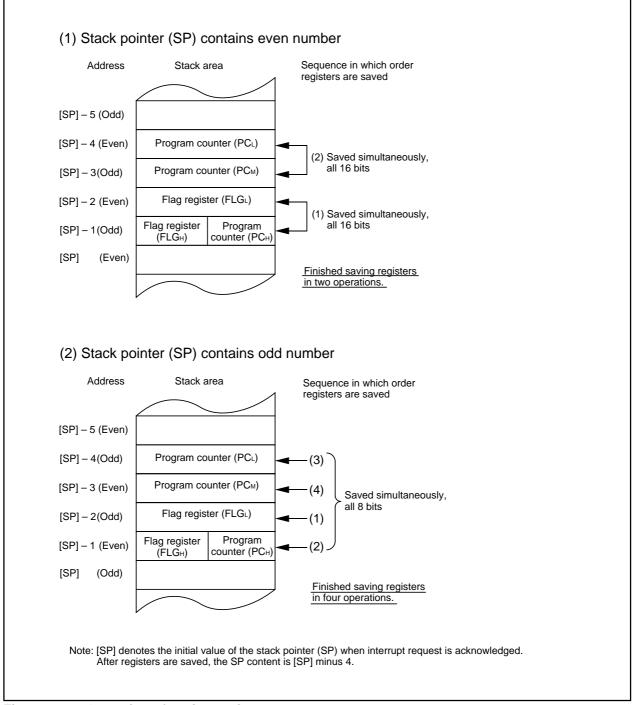

Figure 1.28. Operation of saving registers

### **Returning from an Interrupt Routine**

Executing the REIT instruction at the end of an interrupt routine returns the contents of the flag register (FLG) as it was immediately before the start of interrupt sequence and the contents of the program counter (PC), both of which have been saved in the stack area. Then control returns to the program that was being executed before the acceptance of the interrupt request, so that the suspended process resumes.

Return the other registers saved by software within the interrupt routine using the POPM or similar instruction before executing the REIT instruction.

#### **Interrupt Priority**

If there are two or more interrupt requests occurring at a point in time within a single sampling (checking whether interrupt requests are made), the interrupt assigned a higher priority is accepted.

Assign an arbitrary priority to maskable interrupts (peripheral I/O interrupts) using the interrupt priority level select bit. If the same interrupt priority level is assigned, however, the interrupt assigned a higher hardware priority is accepted.

Priorities of the special interrupts, such as Reset (dealt with as an interrupt assigned the highest priority), watchdog timer interrupt, etc. are regulated by hardware.

Figure 1.29 shows the priorities of hardware interrupts.

Software interrupts are not affected by the interrupt priority. If an instruction is executed, control branches invariably to the interrupt routine.

#### **Interrupt Priority Level Judge Circuit**

This circuit selects the interrupt with the highest priority level when two or more interrupts are generated simultaneously.

Figure 1.30 shows the interrupt resolution circuit.

Reset > DBC > Watchdog timer > Peripheral I/O > Single step > Address match

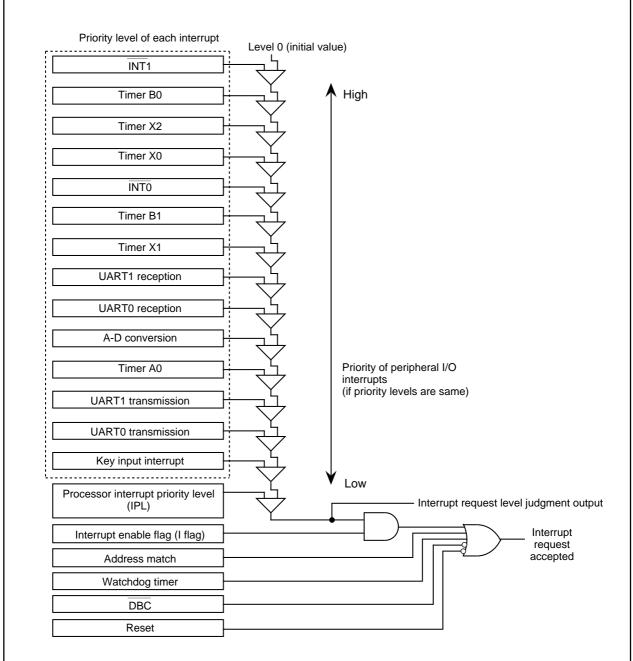

Figure 1.30. Interrupt resolution circuit

#### **Key Input Interrupt**

If the direction register of any of P00 to P07 is set for input and a falling edge is input to that port, a key input interrupt is generated. A key input interrupt can also be used as a key-on wakeup function for cancelling the wait mode or stop mode. Figure 1.31 shows the block diagram of the key input interrupt. Note that if an "L" level is input to any pin that has not been disabled for input, inputs to the other pins are not detected as an interrupt.

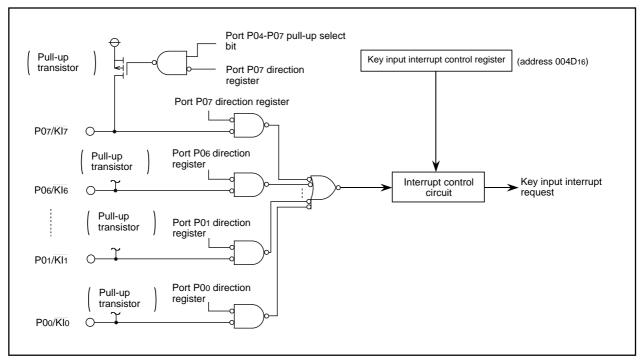

Figure 1.31. Block diagram of key input interrupt

#### **Address Match Interrupt**

An address match interrupt is generated when the address match interrupt address register contents match the program counter value. Two address match interrupts can be set, each of which can be enabled and disabled by an address match interrupt enable bit. Address match interrupts are not affected by the interrupt enable flag (I flag) and processor interrupt priority level (IPL). For an address match interrupt, the value of the program counter (PC) that is saved to the stack area varies depending on the instruction being executed.

Figure 1.32 shows the address match interrupt-related registers.

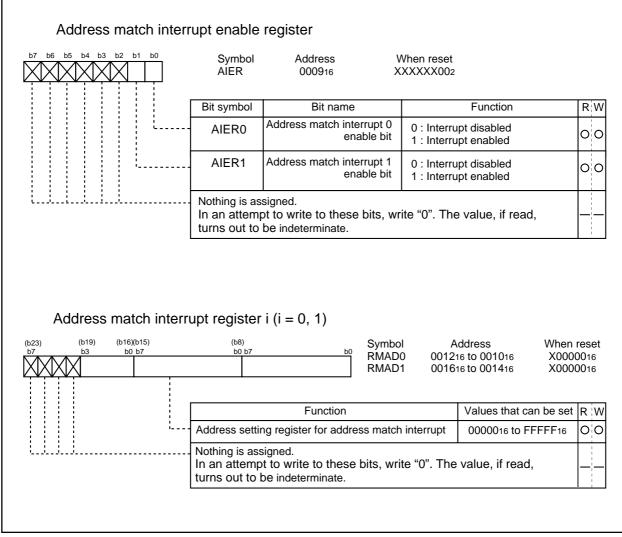

Figure 1.32. Address match interrupt-related registers

# **Precautions for Interrupts**

### (1) Reading address 0000016

• When maskable interrupt is occurred, CPU read the interrupt information (the interrupt number and interrupt request level) in the interrupt sequence.

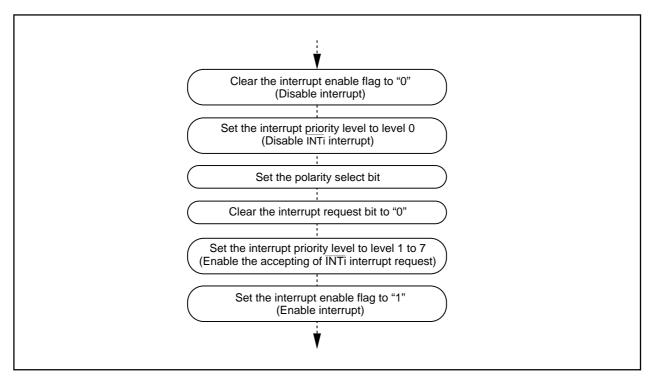

The interrupt request bit of the certain interrupt written in address 0000016 will then be set to "0". Reading address 0000016 by software sets enabled highest priority interrupt source request bit to "0". Though the interrupt is generated, the interrupt routine may not be executed. Do not read address 0000016 by software.

### (2) Setting the stack pointer

• The value of the stack pointer immediately after reset is initialized to 000016. Accepting an interrupt before setting a value in the stack pointer may become a factor of runaway. Be sure to set a value in the stack pointer before accepting an interrupt. Concerning the first instruction immediately after reset, generating any interrupts is prohibited.

### (3) External interrupt

- Either an "L" level or an "H" level of at least 250 ns width is necessary for the signal input to pins INTO and INT1 regardless of the CPU operation clock.
- When changing a polarity of pins INTO and INT1, the interrupt request bit may become "1". Clear the interrupt request bit after changing the polarity. Figure 1.33 shows the switching condition of INT interrupt request.

#### Figure 1.33. Switching condition of INT interrupt request

# (4) Changing interrupt control register

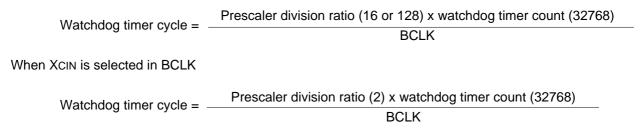

See "Changing Interrupt Control Register".

#### Watchdog Timer

The watchdog timer has the function of detecting when the program is out of control. The watchdog timer is a 15-bit counter which down-counts the clock derived by dividing the BCLK using the prescaler. A watchdog timer interrupt is generated when an underflow occurs in the watchdog timer. When XIN is selected for the BCLK, bit 7 of the watchdog timer control register (address 000F16) selects the prescaler division ratio (by 16 or by 128). When XCIN is selected as the BCLK, the prescaler is set for division by 2 regardless of bit 7 of the watchdog timer control register (address 000F16).

When XIN is selected in BCLK

For example, when BCLK is 10MHz and the prescaler division ratio is set to 16, the watchdog timer cycle is approximately 52.4 ms.

The watchdog timer is initialized by writing to the watchdog timer start register (address 000E16) and when a watchdog timer interrupt request is generated. The prescaler is initialized only when the microcomputer is reset. After a reset is cancelled, the watchdog timer and prescaler are both stopped. The count is started by writing to the watchdog timer start register (address 000E16). In stop mode and wait mode the watchdog timer and prescaler are stopped. Counting is resumed from the held value when the modes are released. Figure 1.34 shows the block diagram of the watchdog timer. Figure 1.35 shows the watchdog timer-related registers.

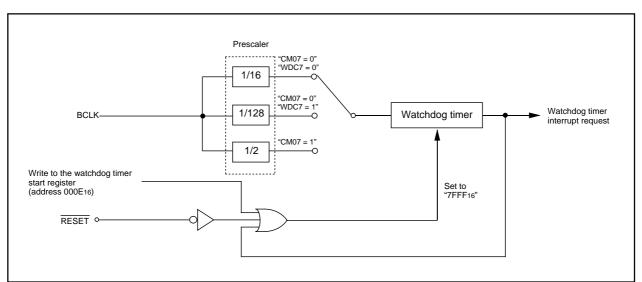

Figure 1.34. Block diagram of watchdog timer

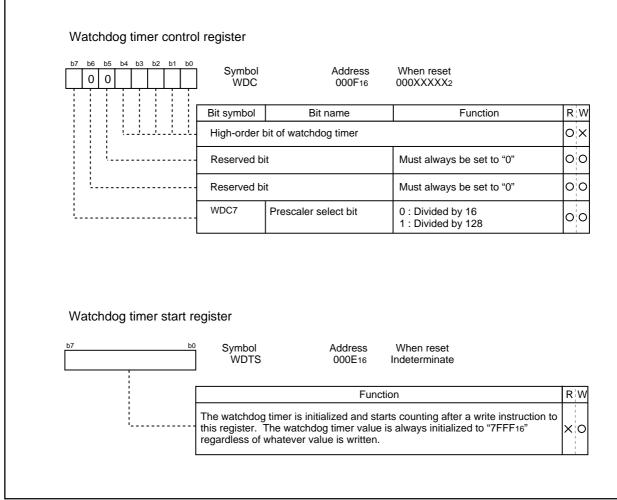

Figure 1.35. Watchdog timer control and start registers

### Timer

# Timer

There are six 16-bit timers. These timers can be classified by function into timer A (one), timers B (two) and timers X (three). All these timers function independently. Figure 1.36 show the block diagram of timers.

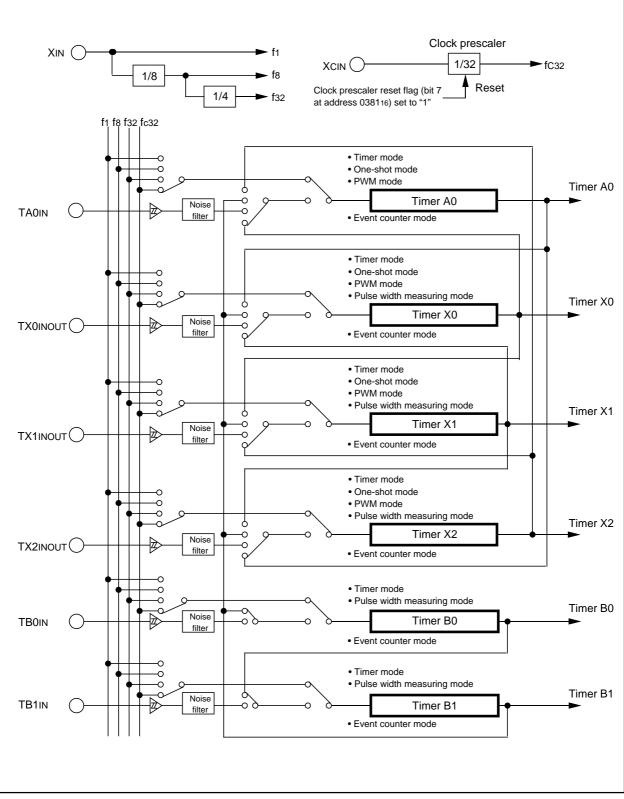

Figure 1.36. Timer block diagram

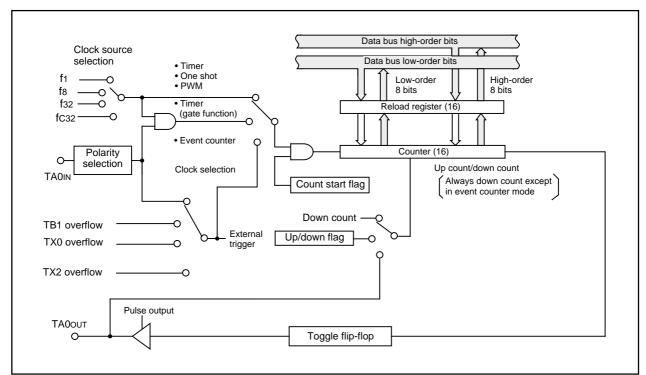

### Timer A

### Timer A

Figure 1.37 shows the block diagram of timer A. Figures 1.38 to 1.40 show the timer A-related registers. Use the timer A0 mode register bits 0 and 1 to choose the desired mode.

Timer A has the four operation modes listed as follows:

- Timer mode: The timer counts an internal count source.
- Event counter mode: The timer counts pulses from an external source or a timer over flow.
- One-shot timer mode: The timer stops counting when the count reaches "000016".
- Pulse width modulation (PWM) mode: The timer outputs pulses of a given width.

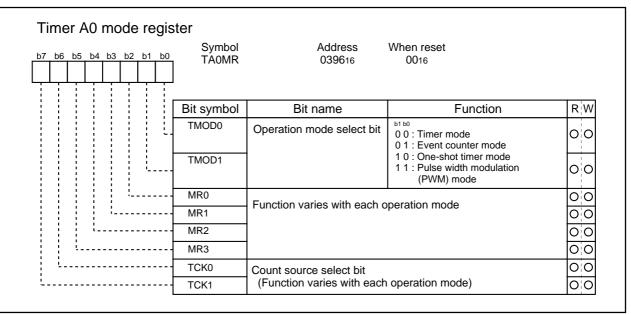

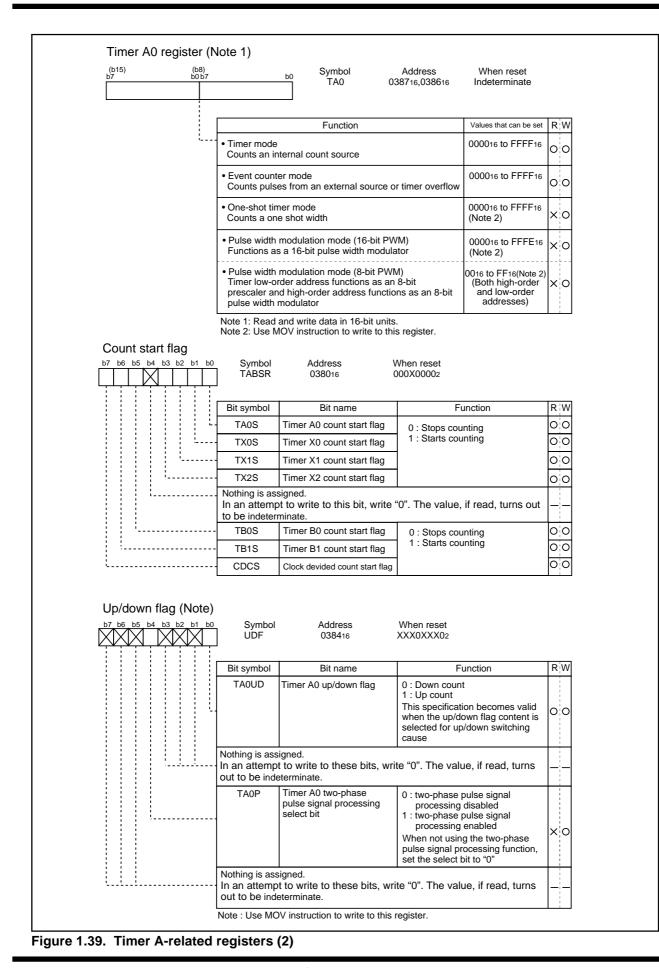

Figure 1.38. Timer A-related registers (1)

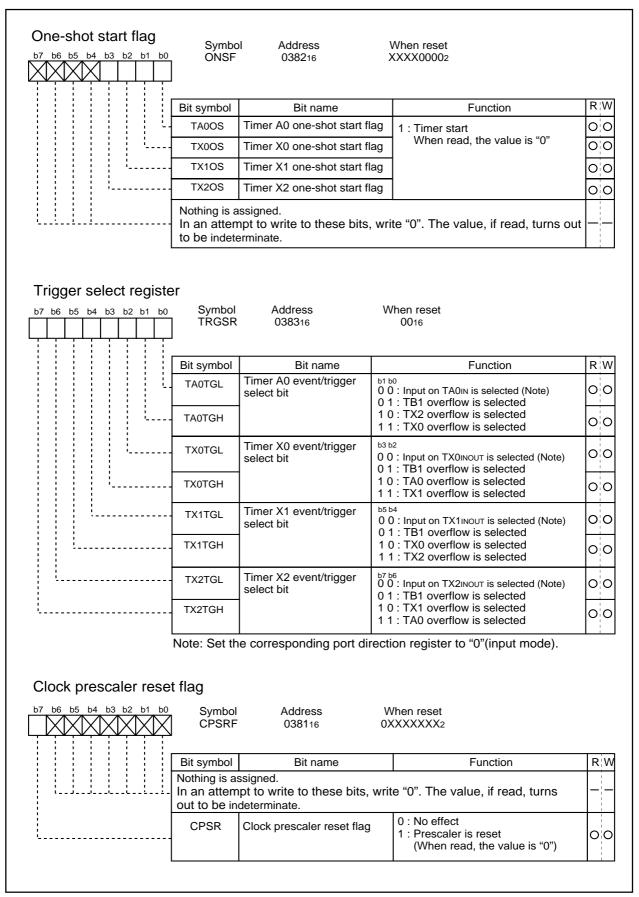

Figure 1.40. Timer A-related registers (3)

### (1) Timer mode

In this mode, the timer counts an internally generated count source. (See Table 1.12.) Figure 1.41 shows the timer A0 mode register in timer mode.

	Table 1.12.	Specifications	of timer	mode

### (2) Event counter mode

In this mode, the timer counts an external signal or an internal timer's overflow. Timer A0 can count a single-phase and a two-phase external signal. Table 1.13 lists timer specifications when counting a single-phase external signal. Figure 1.42 shows the timer A0 mode register in event counter mode. Table 1.14 lists timer specifications when counting a two-phase external signal. Figure 1.43 shows the timer A0 mode register in event counter mode.

Figure 1.44. Timer A0 mode register in one-shot timer mode

# (4) Pulse width modulation (PWM) mode

In this mode, the timer outputs pulses of a given width in succession. (See Table 1.16.) In this mode, the counter functions as either a 16-bit pulse width modulator or an 8-bit pulse width modulator. Figure 1.45 shows the timer A0 mode register in pulse width modulation mode. Figure 1.46 shows the example of how a 16-bit pulse width modulator operates. Figure 1.47 shows the example of how an 8-bit pulse width modulator operates.

Item		Specification			
Count source	f	1, f8, f32, fC32			
Count operation		• The timer counts down (operating as an 8-bit or a 16-bit pulse width modulator)			
-	•	• The timer reloads a new count at a rising edge of PWM pulse and continues counting			
	•	The timer is not affected by a trigger that occurs when counting			
16-bit PWM	•	High level width n / fi n : Set value			
	•	Cycle time (2 <sup>16</sup> -1) / fi fixed			
8-bit PWM	•	High level width $n \times (m+1) / fi$ n : values set to timer A0 register's high-order address			
	•	Cycle time $(2^{8}-1) \times (m+1)$ / fi m : values set to timer A0 register's low-order address			
Count start condition	on 🔸	External trigger is input			
	•	The timer overflows			
	•	• The count start flag is set (= 1)			
Count stop condition	on •	The count start flag is reset (= 0)			
Interrupt 8 bits	PWM •	Set value of "H" level width is except FF16, 0016 : PWM pulse goes "L"			
request	•	Set value of "H" level width is FF16, 0016 : Timing that count value goes to 0116			
generation 16 bits	s PWM 🔸	Set value of "H" level width is except FFFF16, 000016 : PWM pulse goes "L"			
timing	•	Set value of "H" level width is FFFF16, 000016 : Timing that count value goes to 000116			
TA0IN pin function Programmable		Programmable I/O port or trigger input			
TA00UT pin function		Pulse output			
Read from timer		When timer A0 register is read, it indicates an indeterminate value			
Write to timer		• When counting stopped :When a value is written to timer A0 register, it is			
		written to both reload register and counter			
		When counting in progress : When a value is written to timer A0 register, it is			
		written to only reload register (Transferred to counter at next reload time)			

Note: When set value of "H" level width is 0016 or 000016, pulse outputs "L" level and inversion value, FF16 or FFFF16 is set to timer.

#### Timer B

### Timer B

Figure 1.48 shows the block diagram of timer B. Figures 1.49 and 1.50 show the timer B-related registers. Use the timer B mode register (i = 0, 1) bits 0 and 1 to choose the desired mode. Timer B has three operation modes listed as follows:

- Timer mode : The timer counts an internal count source.
- Event counter mode : The timer counts pulses from an external source or a timer overflow.
- Pulse period/pulse width measuring mode : The timer measures an external signal's pulse period or pulse width.

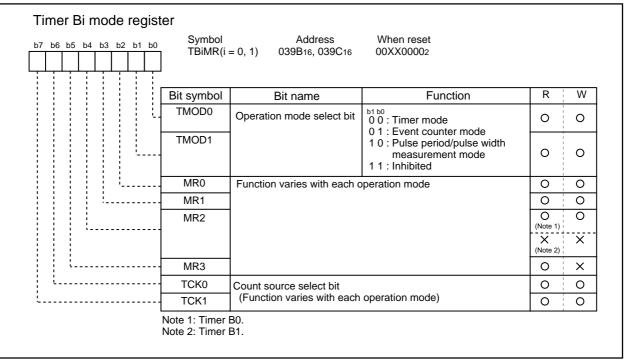

Figure 1.49. Timer B-related registers (1)

Figure 1.52. Timer Bi mode register in event counter mode

### (3) Pulse period/pulse width measurement mode

In this mode, the timer measures the pulse period or pulse width of an external signal. (See Table 1.19.) Figure 1.53 shows the timer Bi mode register in pulse period/pulse width measurement mode. Figure 1.54 shows the operation timing when measuring a pulse period. Figure 1.55 shows the operation timing when measuring a pulse period.

Item	Specification		
Count source	f1, f8, f32, fc32		
Count operation	• Up count		
	Counter value "000016" is transferred to reload register at measurement		
	pulse's effective edge and the timer continues counting		
Count start condition	Count start flag is set (= 1)		
Count stop condition	Count start flag is reset (= 0)		
Interrupt request generation timing	When measurement pulse's effective edge is input (Note 1)		
	When an overflow occurs. (Simultaneously, the timer Bi overflow flag		
	changes to "1". The timer Bi overflow flag changes to "0" when the count		
	start flag is "1" and a value is written to the timer Bi mode register.)		
TBiin pin function	Measurement pulse input		
Read from timer	When timer Bi register is read, it indicates the reload register's content		
	(measurement result) (Note 2)		
Write to timer	Cannot be written to		

Note 1: An interrupt request is not generated when the first effective edge is input after the timer has started counting. Note 2: The value read out from the timer Bi register is indeterminate until the second effective edge is input after the timer.

# Timer X

Figure 1.56 shows the block diagram of timer X. Figures 1.57 to 1.59 show the timer X-related registers. Use the timer Xi mode register bits 0 and 1 to choose the desired mode.

Timer X has the five operation modes listed as follows:

- Timer mode
- : The timer counts an internal count source.
- Event counter mode : The timer counts pulses from an external source or a timer overflow.
- One-shot timer mode : The timer stops counting when the count reaches "000016".
- Pulse period/pulse width measuring mode : The timer measures an external signal's pulse period or pulse width.
- Pulse width modulation (PWM) mode
- : The timer outputs pulses of a given width.

# (2) Event counter mode

In this mode, the timer counts an external signal or an internal timer's overflow. (See Table 1.21.) Figure 1.61 shows the timer Xi mode register in event counter mode.

Table 1.21. Timer specifications in event counter mode (when not processing two-phase pulse signal)

Item	Specification
Count source	• External signals input to TXIINOUT pin (effective edge can be selected by software)
	TB1 overflow, TA0 overflow, TXi overflow
Count operation	Down count
	When the timer underflows, it reloads the reload register contents before
	continuing counting (Note)
Divide ratio	1/ (n + 1) n : Set value
Count start condition	Count start flag is set (= 1)
Count stop condition	Count start flag is reset (= 0)
Interrupt request generation timing	The timer underflows
TXINOUT pin function	Programmable I/O port, count source input or pulse output
Read from timer	Count value can be read out by reading timer Xi register
Write to timer	When counting stopped
	When a value is written to timer Xi register, it is written to both reload register and counter
	When counting in progress
	When a value is written to timer Xi register, it is written to only reload register
	(Transferred to counter at next reload time)
Select function	Free-run count function
	Even when the timer underflows, the reload register content is not reloaded to it
	Pulse output function
	Each time the timer underflows, the TXIINOUT pin's polarity is reversed

Note: This does not apply when the free-run function is selected.

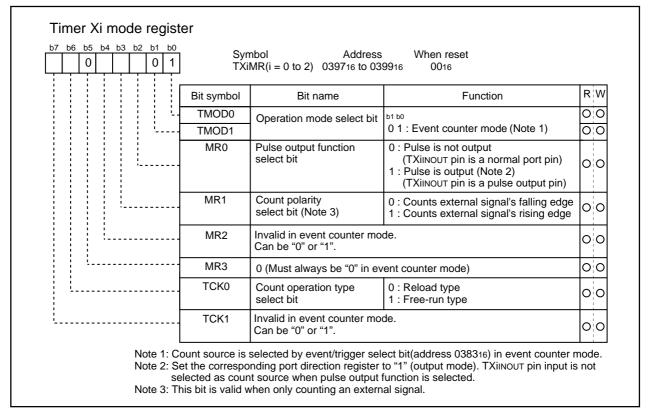

Figure 1.61. Timer Xi mode register in event counter mode

# (3) One-shot timer mode

In this mode, the timer operates only once. (See Table 1.22.) When a trigger occurs, the timer starts up and continues operating for a given period. Figure 1.62 shows the timer Xi mode register in one-shot timer mode.

Table 1.22. Timer specifications in one-shot timer mod

Figure 1.62. Timer Xi mode register in one-shot timer mode

# (4) Pulse period/pulse width measurement mode

In this mode, the timer measures the pulse period or pulse width of an external signal. (See Table 1.23.) Figure 1.63 shows the timer Xi mode register in pulse period/pulse width measurement mode. Figure 1.64 shows the operation timing when measuring a pulse period. Figure 1.65 shows the operation timing when measuring a pulse period.

Item	Specification		
Count source	f1, f8, f32, fc32		
Count operation	• Up count		
	Counter value "000016" is transferred to reload register at measurement		
	pulse's effective edge and the timer continues counting		
Count start condition	Count start flag is set (= 1)		
Count stop condition	Count start flag is reset (= 0)		
Interrupt request generation timing	When measurement pulse's effective edge is input (Note 1)		
	When an overflow occurs. (Simultaneously, the timer Xi overflow flag		
	changes to "1". The timer Xi overflow flag changes to "0" when the count		
	start flag is "1" and a value is written to the timer Xi mode register.)		
TXINOUT pin function	Measurement pulse input		
Read from timer	When timer Xi register is read, it indicates the reload register's content		
	(measurement result) (Note 2)		
Write to timer	Cannot be written to		

Table 1.23. Timer specifications in pulse period/pulse width measurement mode

Note 1: An interrupt request is not generated when the first effective edge is input after the timer has started counting. Note 2: The value read out from the timer Xi register is indeterminate until the second effective edge is input after the timer.

Figure 1.64. Operation timing when measuring a pulse period

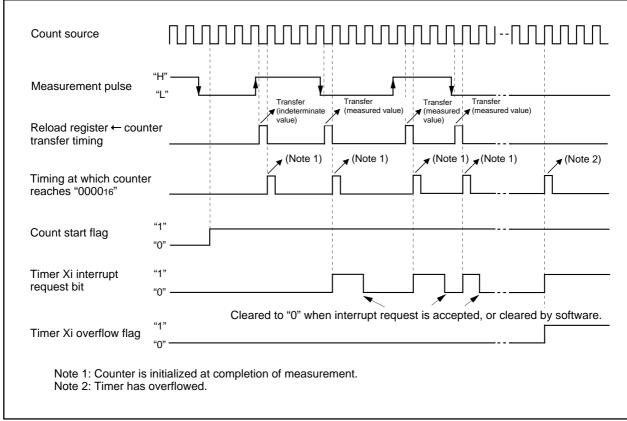

Figure 1.65. Operation timing when measuring a pulse width

# (5) Pulse width modulation (PWM) mode

In this mode, the timer outputs pulses of a given width in succession. (See Table 1.24.) In this mode, the counter functions as either a 16-bit pulse width modulator or an 8-bit pulse width modulator. Figure 1.66 shows the timer Xi mode register in pulse width modulation mode. Figure 1.67 shows the example of how a 16-bit pulse width modulator operates. Figure 1.68 shows the example of how an 8-bit pulse width modulator operates.

Item		Specification	
Count source		f1, f8, f32, fC32	
Count operation		Down counts (operating as an 8-bit or a 16-bit pulse width modulator)	
		• The timer reloads a new count at a rising edge of PWM pulse and continues counting	
		The timer is not affected by a trigger that occurs when counting	
16-bit PWM		"H" level width n / fi n : Set value	
		Cycle time (2 <sup>16</sup> -1) / fi fixed	
8-bit PWM		• "H" level width $n \times (m+1)$ / fi n:values set to timer Xi register's high-order address	
		• Cycle time (2 <sup>8</sup> -1)×(m+1) / fi m : values set to timer Xi register's low-order address	
Count start condition		The timer overflows	
		• The count start flag is set (= 1)	
Count stop condition		• The count start flag is reset (= 0)	
Interrupt	8 bits PWM	Set value of "H" level width is except FF16, 0016 : PWM pulse goes "L"	
request		• Set value of "H" level width is FF16, 0016 : Timing that count value goes to 0116	
generation	16 bits PWM	• Set value of "H" level width is except FFFF16, 000016 : PWM pulse goes "L"	
timing		• Set value of "H" level width is FFFF16, 000016 : Timing that count value goes to 000116	
TXIINOUT pin function		Pulse output	
Read from timer		When timer Xi register is read, it indicates an indeterminate value	
Write to timer		When counting stopped	
		When a value is written to timer Xi register, it is written to both reload register and counter	
		When counting in progress	
		When a value is written to timer Xi register, it is written to only reload register	
		(Transferred to counter at next reload time)	

Table 1.24. Timer specifications in pulse width modulation mode

Note: When set value of "H" level width is 0016 or 000016, pulse outputs "L" level and inversion value, FF16 or FFFF16 is set to timer.

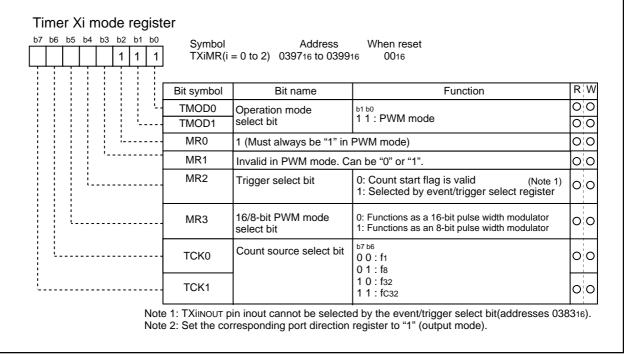

Figure 1.66. Timer Xi mode register in pulse width modulation mode

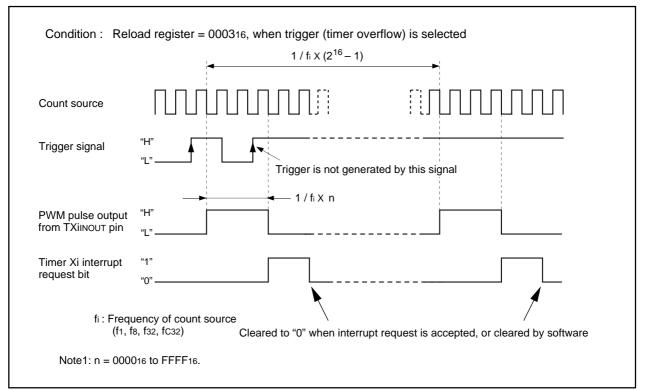

Figure 1.67. Example of how a 16-bit pulse width modulator operates

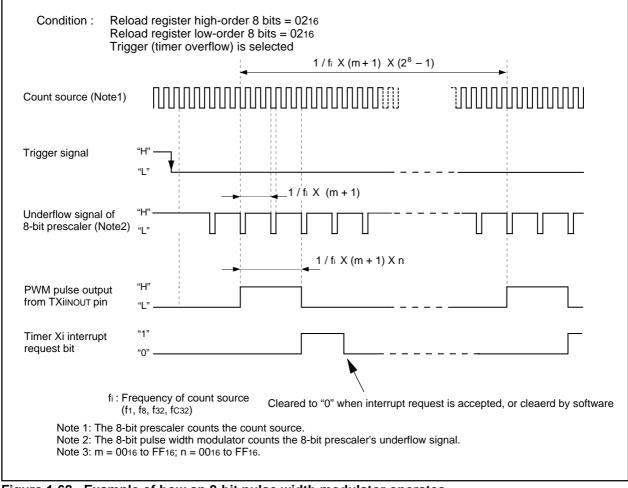

Figure 1.68. Example of how an 8-bit pulse width modulator operates

# Serial I/O

Serial I/O is configured as two channels: UART0 and UART1.

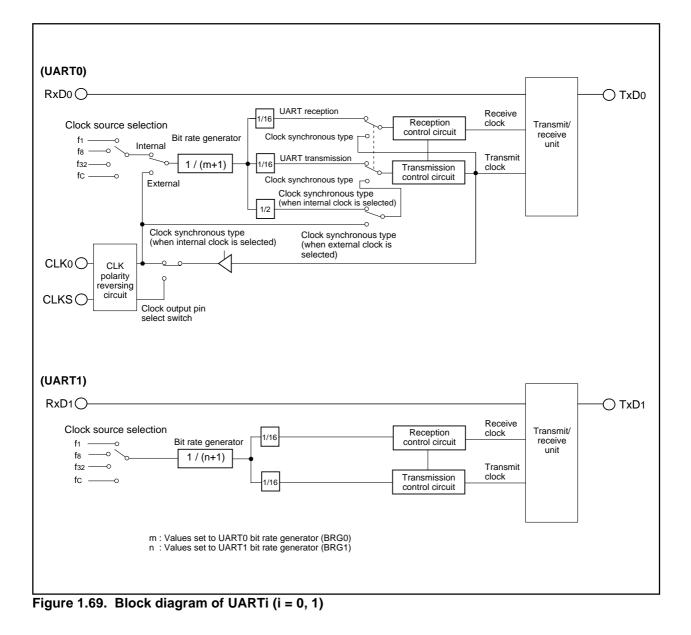

UART0 and UART1 each have an exclusive timer to generate a transfer clock, so they operate independently of each other.

Figure 1.69 shows the block diagram of UART0 and UART1. Figure 1.70 shows the block diagram of the transmit/receive unit.

UART0 has two operation modes: a clock synchronous serial I/O mode and a clock asynchronous serial I/ O mode (UART mode). The contents of the serial I/O mode select bits (bits 0 to 2 at addresses 03A016 and 03A816) determine whether UART0 is used as a clock synchronous serial I/O or as a UART.

UART1 is used as a UART only.

Figures 1.71 through 1.73 show the registers related to UARTi.

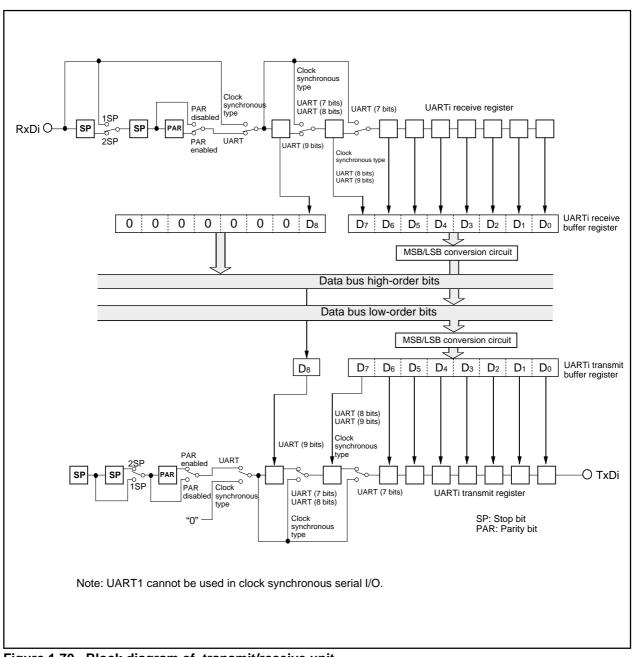

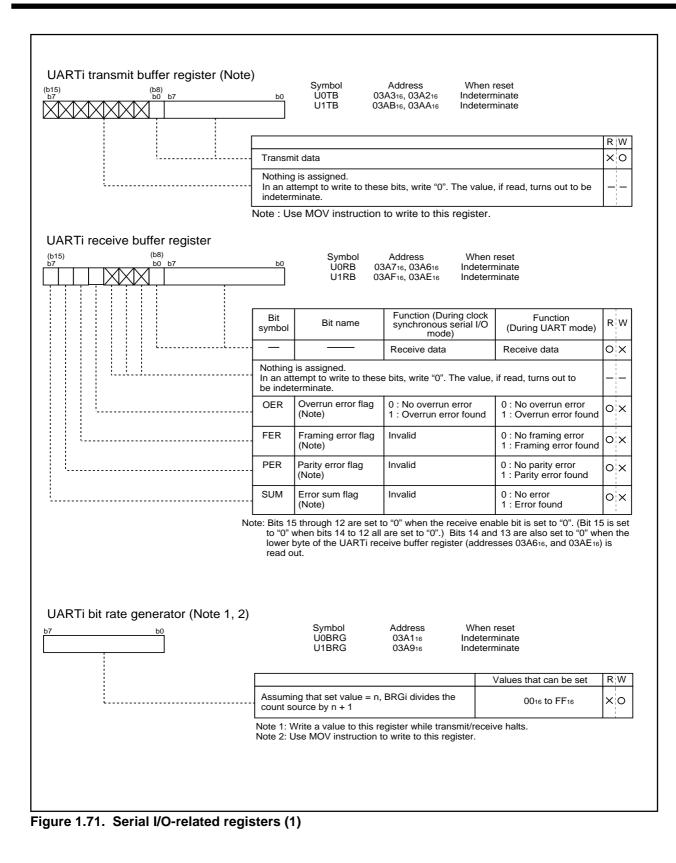

Figure 1.70. Block diagram of transmit/receive unit

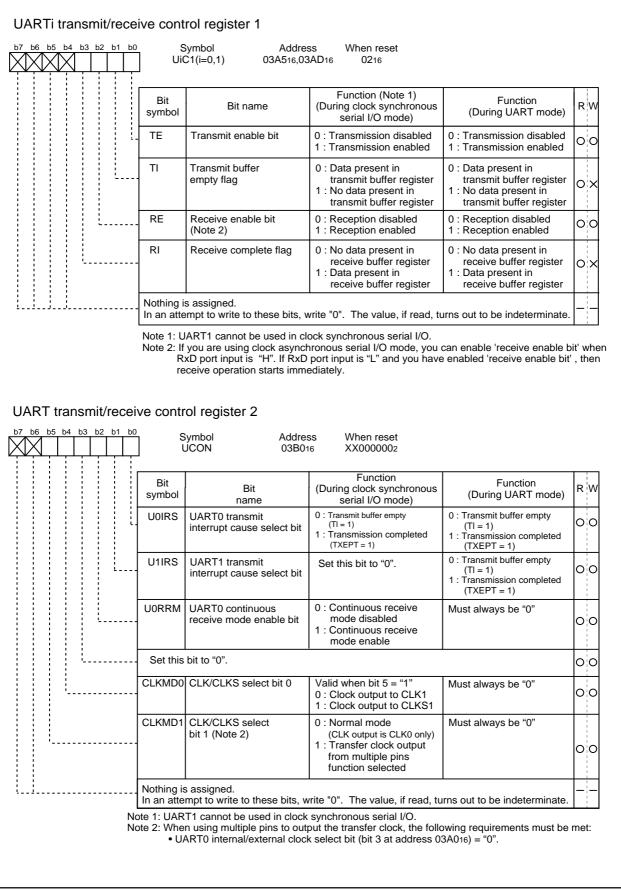

Figure 1.73. Serial I/O-related registers (3)

# (1) Clock synchronous serial I/O mode

The clock synchronous serial I/O mode uses a transfer clock to transmit and receive data. (See Table 1.25.) Figure 1.65 shows the UART0 transmit/receive mode register.

Table 1.25.	Specifications of	clock synchronous	serial I/O mode
-------------	-------------------	-------------------	-----------------

Item	Specification
Transfer data format	Transfer data length: 8 bits
Transfer clock	• When internal clock is selected (bit 3 at address 03A016 = "0") : fi/ 2(n+1) (Note 1)
	fi = f1, f8, f32, fC
	• When external clock is selected (bit 3 at address 03A016 = "1") : Input from CLK0 pin
Transmission start	• To start transmission, the following requirements must be met:
condition	– Transmit enable bit (bit 0 at address 03A516) = "1"
	<ul> <li>Transmit buffer empty flag (bit 1 at addresses 03A516) = "0"</li> </ul>
	• Furthermore, if external clock is selected, the following requirements must also be met:
	- CLK0 polarity select bit (bit 6 at address 03A416) = "0": CLK0 input level = "H"
	- CLK0 polarity select bit (bit 6 at address 03A416) = "1": CLK0 input level = "L"
Reception start	To start reception, the following requirements must be met:
conditio	– Receive enable bit (bit 2 at address 03A516) = "1"
	– Transmit enable bit (bit 0 at address 03A516) = "1"
	- Transmit buffer empty flag (bit 1 at address 03A516) = "0"
	• Furthermore, if external clock is selected, the following requirements must also be met:
	- CLK0 polarity select bit (bit 6 at address 03A416) = "0": CLK0 input level = "H"
	- CLK0 polarity select bit (bit 6 at address 03A416) = "1": CLK0 input level = "L"
Interrupt request	When transmitting
generation timing	- Transmit interrupt cause select bit (bit 0 at address 03B016) = "0": Interrupts re-
	quested when data transfer from UART0 transfer buffer register to UART0 transmit
	register is completed
	- Transmit interrupt cause select bit (bit 0 at address 03B016) = "1": Interrupts re-
	quested when data transmission from UART0 transfer register is completed
	When receiving
	– Interrupts requested when data transfer from UART0 receive register to UART0
	receive buffer register is completed
Error detection	Overrun error (Note 2)
	This error occurs when the next data is ready before contents of UART0 receive
	buffer register are read out
Select function	CLK polarity selection
	Whether transmit data is output/input at the rising edge or falling edge of the trans-
	fer clock can be selected
	LSB first/MSB first selection
	Whether transmission/reception begins with bit 0 or bit 7 can be selected
	Continuous receive mode selection
	Reception is enabled simultaneously by a read from the receive buffer register
	Transfer clock output from multiple pins selection
	UART0 transfer clock can be chosen by software to be output from one of the two
	pins set

Note 1: "n" denotes the value 0016 to FF16 that is set to the UART bit rate generator.

Note 2: If an overrun error occurs, the UART0 receive buffer will have the next data written in. Note also that the UART0 receive interrupt request bit does not change.

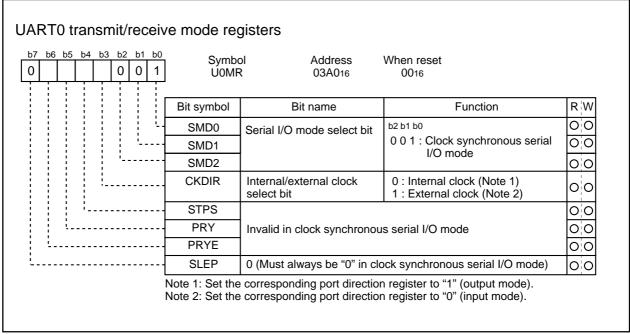

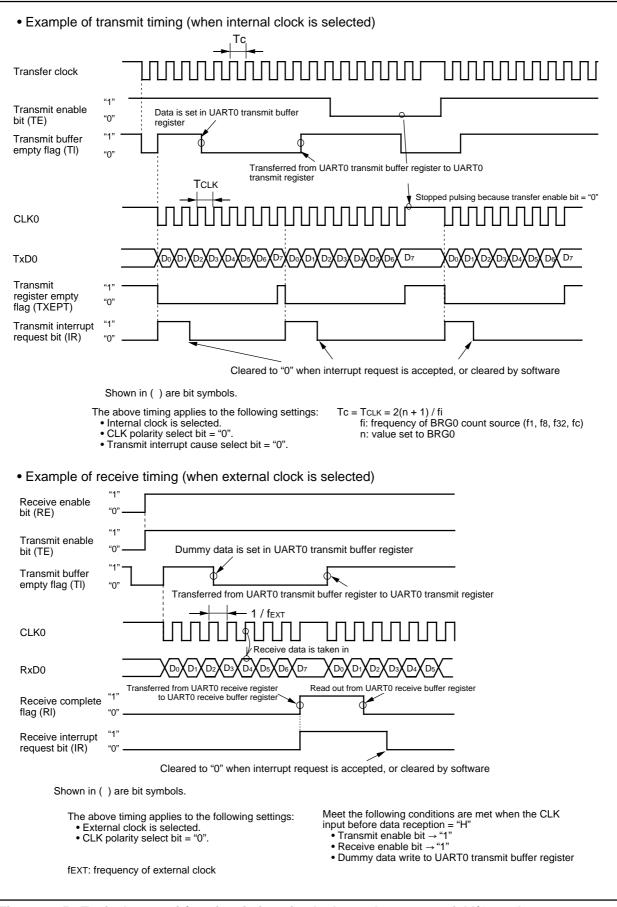

Figure 1.74. UART0 transmit/receive mode register in clock synchronous serial I/O mode

Table 1.26 lists the functions of the input/output pins during clock synchronous serial I/O mode. Note that for a period from when the UART0 operation mode is selected to when transfer starts, the TxD0 pin outputs a "H". (If the N-channel open-drain is selected, this pin is in floating state.)

Table 1.26.	Input/output	pin functions in clock s	ynchronous serial I/O mode
-------------	--------------	--------------------------	----------------------------

Pin name	Function	Method of selection
TxD0 (P50)	Serial data output	Port P50 direction register (bit 0 at address 03EB16)= "1" (Outputs dummy data when performing reception only)
RxD0 (P51)	Serial data input	Port P51 direction register (bit 1 at address 03EB16)= "0" (Can be used as an input port when performing transmission only)
CLK0	Transfer clock output	Internal/external clock select bit (bit 3 at address 03A016) = "0"
(P52)	Transfer clock input	Internal/external clock select bit (bit 3 at address 03A016) = "1" Port P52 direction register (bit 2 at address 03EB16) = "0"

#### (a) Polarity select function

As shown in Figure 1.76, the CLK polarity select bit (bit 6 at addresses 03A416) allows selection of the polarity of the transfer clock.

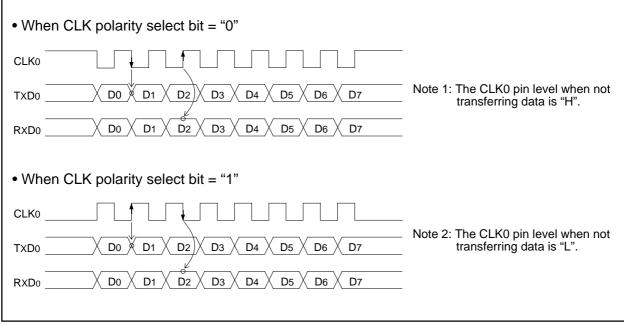

Figure 1.76. Polarity of transfer clock

#### (b) LSB first/MSB first select function

As shown in Figure 1.77, when the transfer format select bit (bit 7 at addresses 03A416) = "0", the transfer format is "LSB first"; when the bit = "1", the transfer format is "MSB first".

	transfer format select bit = "0"	
TXD0	$\begin{array}{c ccccccccccccccccccccccccccccccccccc$	
RXD0	D0 \ D1 \ D2 \ D3 \ D4 \ D5 \ D6 \ D7	► LSB first
• When t	ransfer format select bit = "1"	
CLK0		
TXD0	D7 \ D6 \ D5 \ D4 \ D3 \ D2 \ D1 \ D0	➡ MSB first
	D7 \ D6 \ D5 \ D4 \ D3 \ D2 \ D1 \ D0	
RXD0		

#### (c) Transfer clock output from multiple pins function

This function allows the setting two transfer clock output pins and choosing one of the two to output a clock by using the CLK and CLKS select bit (bits 4 and 5 at address 03B016). (See Figure 1.78.) The multiple pins function is valid only when the internal clock is selected for UART0.

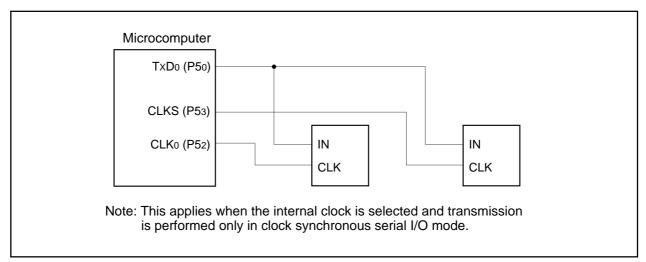

Figure 1.78. The transfer clock output from the multiple pins function usage

#### (d) Continuous receive mode

If the continuous receive mode enable bit (bits 2 and 3 at address 03B016) is set to "1", the unit is placed in continuous receive mode. In this mode, when the receive buffer register is read out, the unit simultaneously goes to a receive enable state without having to set dummy data to the transmit buffer register back again.

# (2) Clock asynchronous serial I/O (UART) mode

The UART mode allows transmitting and receiving data after setting the desired transfer rate and transfer data format. (See Table 1.27.) Figure 1.79 shows the UARTi transmit/receive mode register.

Item	Specification
Transfer data format	Character bit (transfer data): 7 bits, 8 bits, or 9 bits as selected
	Start bit: 1 bit
	Parity bit: Odd, even, or nothing as selected
	Stop bit: 1 bit or 2 bits as selected
Transfer clock	• When internal clock is selected (bit 3 at addresses 03A016, 03A816 = "0") :
	fi/16(n+1) (Note 1) fi = f1, f8, f32, fC
	• When external clock is selected (bit 3 at addresses 03A016="1") :
	fEXT/16(n+1) (Note 1) (Note 2)
Transmission start	• To start transmission, the following requirements must be met:
condition	- Transmit enable bit (bit 0 at addresses 03A516, 03AD16) = "1"
	- Transmit buffer empty flag (bit 1 at addresses 03A516, 03AD16) = "0"
Reception start condi-	• To start reception, the following requirements must be met:
tion	- Receive enable bit (bit 2 at addresses 03A516, 03AD16) = "1"
	- Start bit detection
Interrupt request gen-	When transmitting
eration timing	- Transmit interrupt cause select bits (bits 0,1 at address 03B016) = "0":
	Interrupts requested when data transfer from UARTi transfer buffer register
	to UARTi transmit register is completed
	- Transmit interrupt cause select bits (bits 0, 1 at address 03B016) = "1":
	Interrupts requested when data transmission from UARTi transfer register is completed
	When receiving
	- Interrupts requested when data transfer from UARTi receive register to
	UARTi receive buffer register is completed
Error detection	Overrun error (Note 3)
	This error occurs when the next data is ready before contents of UARTi receive buffer register are read out
	Framing error
	This error occurs when the number of stop bits set is not detected
	Parity error
	This error occurs when if parity is enabled, the number of 1's in parity and
	character bits does not match the number of 1's set
	Error sum flag
	This flag is set (= 1) when any of the overrun, framing, and parity errors is
	encountered
Select function	Sleep mode selection
	This mode is used to transfer data to and from one of multiple slave micro-
	computers

Table 1.27. Specifications of UART Mode

Note 1: 'n' denotes the value 0016 to FF16 that is set to the UART bit rate generator.

Note 2: fEXT is input from the CLK0 pin. Since UART1 does not have this pin, cannot select external clock. Note 3: If an overrun error occurs, the UARTi receive buffer will have the next data written in. Note also that the UARTi receive interrupt request bit does not change.

Figure 1.79. UARTi transmit/receive mode register in UART mode

Table 1.28 lists the functions of the input/output pins during UART mode. Note that for a period from when the UARTi operation mode is selected to when transfer starts, the TxDi pin outputs a "H". (If the N-channel open-drain is selected, this pin is in floating state.)

Pin name	Function	Method of selection
TxDi (P50, P40)	Serial data output	Port P51 and P42 direction register (bit 0 at address 03EB16, bit 0 at address 03EA16)= "1" (Can be used as an input port when performing reception only)
RxDi (P51, P42)	Serial data input	Port P51 and P42 direction register (bit 1 at address 03EB16, bit 2 at address 03EA16)= "0" (Can be used as an input port when performing transmission only)
CLK0	Programmable I/O port	Internal/external clock select bit (bit 3 at address 03A016) = "0"
(P52)	Transfer clock input	Internal/external clock select bit (bit 3 at address 03A016) = "1"

Table 1.28. Input/output pin functions in UART mode

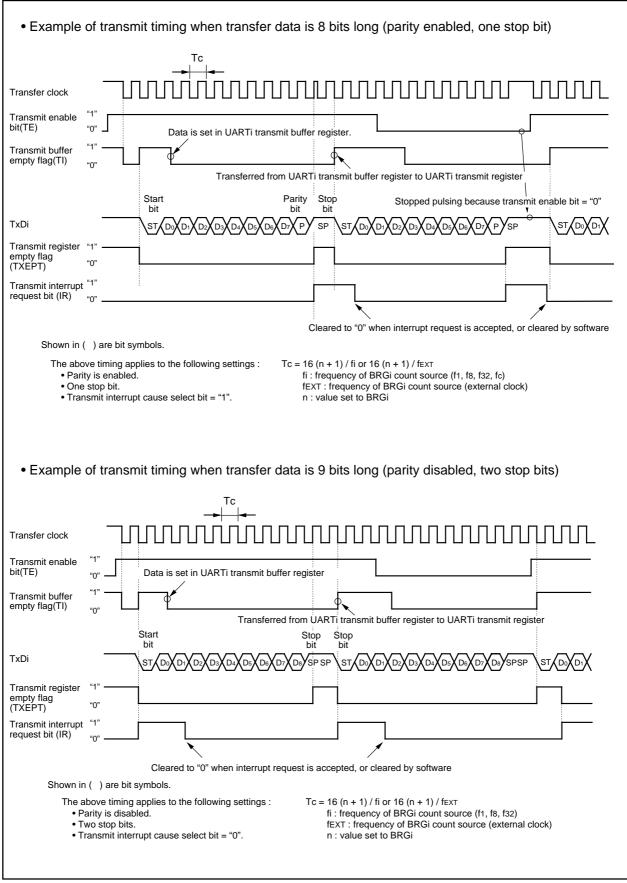

Figure 1.80. Typical transmit timings in UART mode

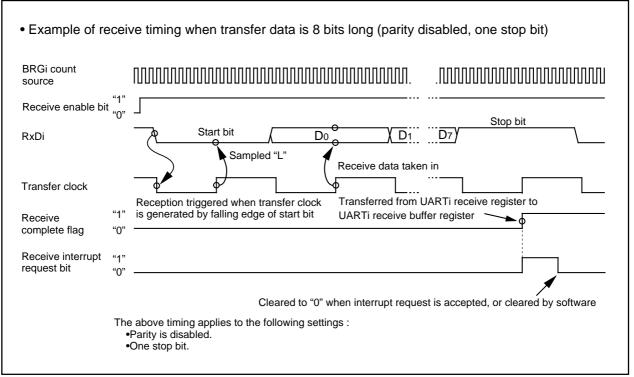

Figure 1.81. Typical receive timing in UART mode

#### (a) Sleep mode

This mode is used to transfer data between specific microcomputers among multiple microcomputers connected using UARTi. The sleep mode is selected when the sleep select bit (bit 7 at addresses 03A016, 03A816) is set to "1" during reception. In this mode, the unit performs receive operation when the MSB of the received data = "1" and does not perform receive operation when the MSB = "0".

# **A-D Converter**

The A-D converter consists of one 10-bit successive approximation A-D converter circuit with a capacitive coupling amplifier. Pins P60 to P67, and P50 to P54 also function as the analog signal input pins. The direction registers of these pins for A-D conversion must therefore be set to input. The Vref connect bit (bit 5 at address 03D716) can be used to isolate the resistance ladder of the A-D converter from the reference voltage input pin (VREF) when the A-D converter is not used. Doing so stops any current flowing into the resistance ladder from VREF, reducing the power dissipation. When using the A-D converter, start A-D conversion only after setting bit 5 of 03D716 to connect VREF.

The result of A-D conversion is stored in the A-D registers of the selected pins. When set to 10-bit precision, the low 8 bits are stored in the even addresses and the high 2 bits in the odd addresses. When set to 8-bit precision, the low 8 bits are stored in the even addresses.

Table 1.29 shows the performance of the A-D converter. Figure 1.82 shows the block diagram of the A-D converter, and Figures 1.83 and 1.84 show the A-D converter-related registers.

Item	Performance
Method of A-D conversion	Successive approximation (capacitive coupling amplifier)
Analog input voltage (Note 1)	0V to AVcc (Vcc)
Operating clock $\phi$ AD (Note 2)	VCC = 5V fAD, divide-by-2 of fAD, divide-by-4 of fAD, fAD=f(XIN)
	Vcc = $3V$ divide-by-2 of fAD, divide-by-4 of fAD, fAD=f(XIN)
Resolution	8-bit or 10-bit (selectable)
Absolute precision	Vcc = 5V • Without sample and hold function
	±3LSB
	<ul> <li>With sample and hold function (8-bit resolution)</li> </ul>
	±2LSB
	<ul> <li>With sample and hold function (10-bit resolution)</li> </ul>
	±3LSB
	Vcc = 3V • Without sample and hold function (8-bit resolution)
	±2LSB
Operating modes	One-shot mode, repeat mode, single sweep mode, repeat sweep mode 0,
	and repeat sweep mode 1
Analog input pins	8 pins (AN0 to AN7) + 5 pins (AN50 to AN54)
A-D conversion start condition	Software trigger
	A-D conversion starts when the A-D conversion start flag changes to "1"
Conversion speed per pin	Without sample and hold function
	8-bit resolution: 49 (AD cycles, 10-bit resolution: 59 (AD cycles
	With sample and hold function
	8-bit resolution: 28 ¢AD cycles, 10-bit resolution: 33 ¢AD cycles

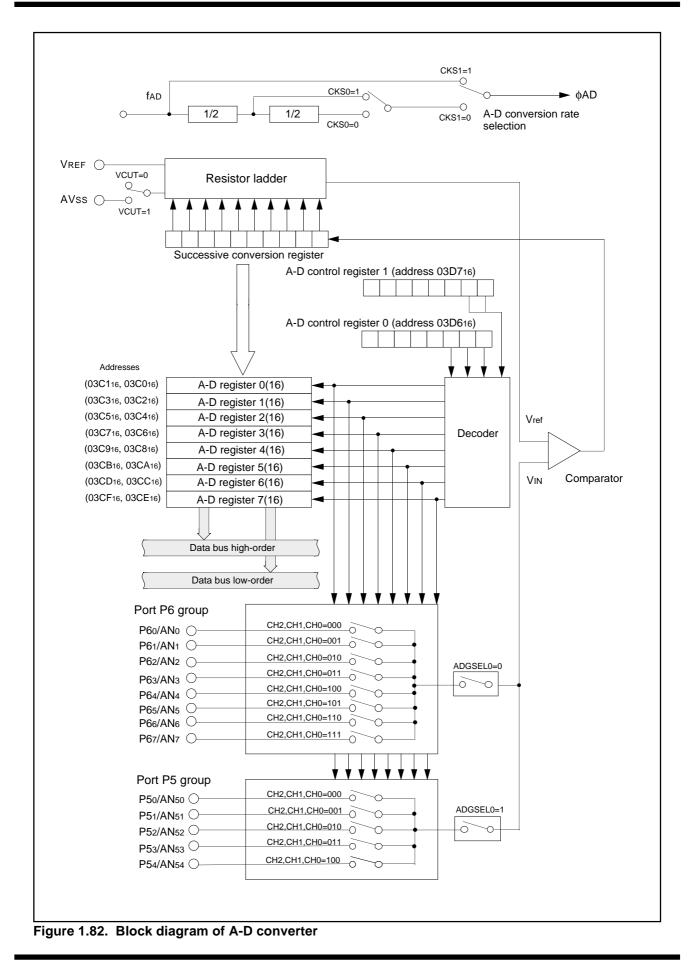

Table 1.29.	Performance	of A-D	converter
-------------	-------------	--------	-----------

Note 1: Does not depend on use of sample and hold function.

Note 2: Without sample and hold function, set the  $\phi$ AD frequency to 250kHz min.

With the sample and hold function, set the  $\phi$ AD frequency to 1MHz min.

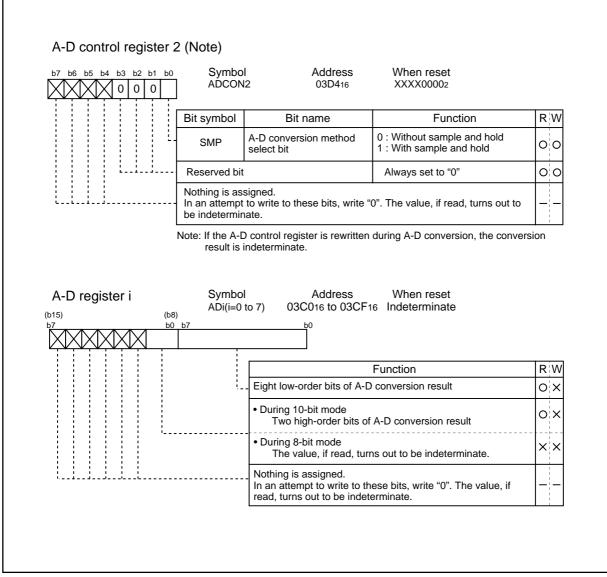

Figure 1.84. A-D converter-related registers (2)

## (1) One-shot mode

In one-shot mode, the pin selected using the analog input pin select bit is used for one-shot A-D conversion. (See Table 1.30.) Figure 1.85 shows the A-D control register in one-shot mode.

Table 1.30. One-shot mode specifications

Specification		
The pin selected by the analog input pin select bit is used for one A-D conversion		
Writing "1" to A-D conversion start flag		
• End of A-D conversion (A-D conversion start flag changes to "0")		
<ul> <li>Writing "0" to A-D conversion start flag</li> </ul>		
End of A-D conversion		
One of AN <sub>0</sub> to AN <sub>7</sub> , as selected (Note)		
Read A-D register corresponding to selected pin		

Note : AN50 to AN54 can be used in the same way as for AN0 to AN4.

b6 b5 b4 b3 b2 b1 b0	Symbol ADCON		When reset 00000XXX2	
	Bit symbol	Bit name	Function	RW

Figure 1.85. A-D conversion register in one-shot mode

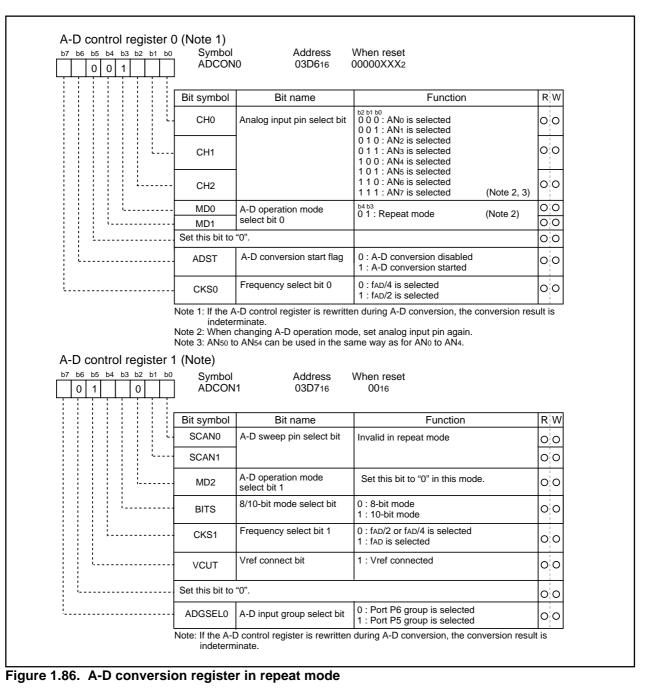

# (2) Repeat mode

In repeat mode, the pin selected using the analog input pin select bit is used for repeated A-D conversion. (See Table 1.31.) Figure 1.86 shows the A-D control register in repeat mode.

Table 1.31.	Repeat mode specifications
-------------	----------------------------

Item	Specification
Function	The pin selected by the analog input pin select bit is used for repeated A-D conversion
Start condition	Writing "1" to A-D conversion start flag
Stop condition	Writing "0" to A-D conversion start flag
Interrupt request generation timing	None generated
Input pin	One of ANo to AN7, as selected (Note)
Reading of result of A-D converter	Read A-D register corresponding to selected pin (at any time)

Note : AN50 to AN54 can be used in the same way as for AN0 to AN4.

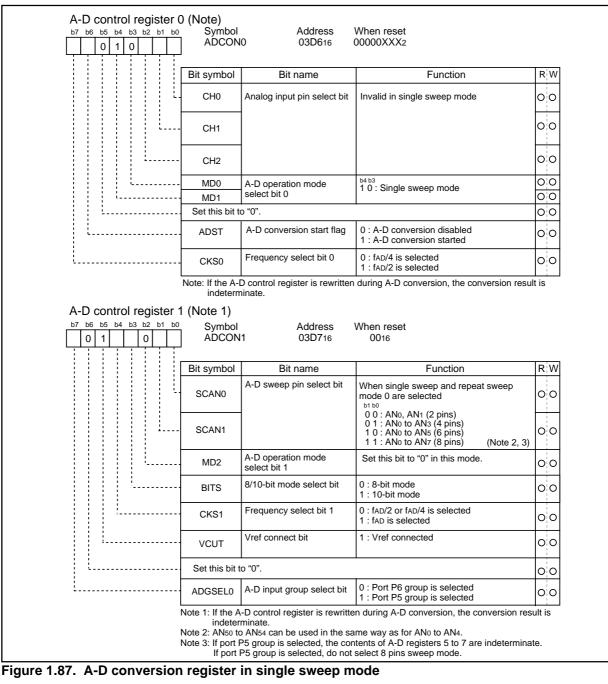

## (3) Single sweep mode

In single sweep mode, the pins selected using the A-D sweep pin select bit are used for one-by-one A-D conversion. (See Table 1.32.) Figure 1.87 shows the A-D control register in single sweep mode.

Table 1.32. Single sweep mode specifications

Specification		
The pins selected by the A-D sweep pin select bit are used for one-by-one A-D conversion		
Writing "1" to A-D converter start flag		
• End of A-D conversion (A-D conversion start flag changes to "0".)		
<ul> <li>Writing "0" to A-D conversion start flag</li> </ul>		
End of A-D conversion		
ANo and AN1 (2 pins), ANo to AN3 (4 pins), ANo to AN5 (6 pins), or ANo to AN7 (8 pins)(Note)		
Read A-D register corresponding to selected pin		

Note : AN50 to AN54 can be used in the same way as for AN0 to AN4.

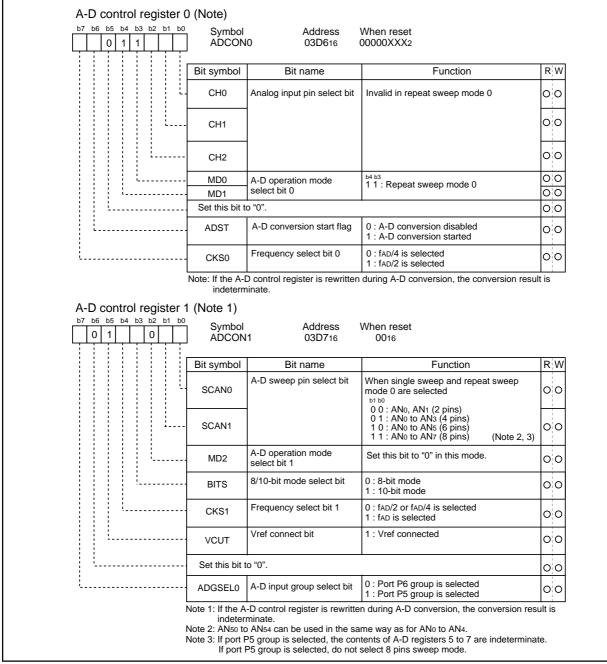

## (4) Repeat sweep mode 0

In repeat sweep mode 0, the pins selected using the A-D sweep pin select bit are used for repeat sweep A-D conversion. (See Table 1.33.) Figure 1.88 shows the A-D control register in repeat sweep mode 0.

Table 1.33. Repeat sweep mode 0 specifications

Specification		
The pins selected by the A-D sweep pin select bit are used for repeat sweep A-D conversion		
Writing "1" to A-D conversion start flag		
Writing "0" to A-D conversion start flag		
None generated		
ANo and AN1 (2 pins), ANo to AN3 (4 pins), ANo to AN5 (6 pins), or ANo to AN7 (8 pins)(Note)		
Read A-D register corresponding to selected pin (at any time)		

Note : AN50 to AN54 can be used in the same way as for AN0 to AN4.

#### (5) Repeat sweep mode 1

In repeat sweep mode 1, all pins are used for A-D conversion with emphasis on the pin or pins selected using the A-D sweep pin select bit. (See Table 1.34.) Figure 1.89 shows the A-D control register in repeat sweep mode 1.

#### Table 1.34. Repeat sweep mode 1 specifications

Item	Specification		
Function	All pins perform repeat sweep A-D conversion, with emphasis on the pin or		
	pins selected by the A-D sweep pin select bit		
	Example : ANo selected ANo $\rightarrow$ AN1 $\rightarrow$ ANo $\rightarrow$ AN2 $\rightarrow$ ANo $\rightarrow$ AN3, etc		
Start condition	Writing "1" to A-D conversion start flag		
Stop condition	Writing "0" to A-D conversion start flag		
Interrupt request generation timing	None generated		
Input pin	AN0 (1 pin), AN0 and AN1 (2 pins), AN0 to AN2 (3 pins), AN0 to AN3 (4 pins) (Note)		
Reading of result of A-D converter	Read A-D register corresponding to selected pin (at any time)		
Note : AN50 to AN54 can be	e used in the same way as for ANo to AN4.		

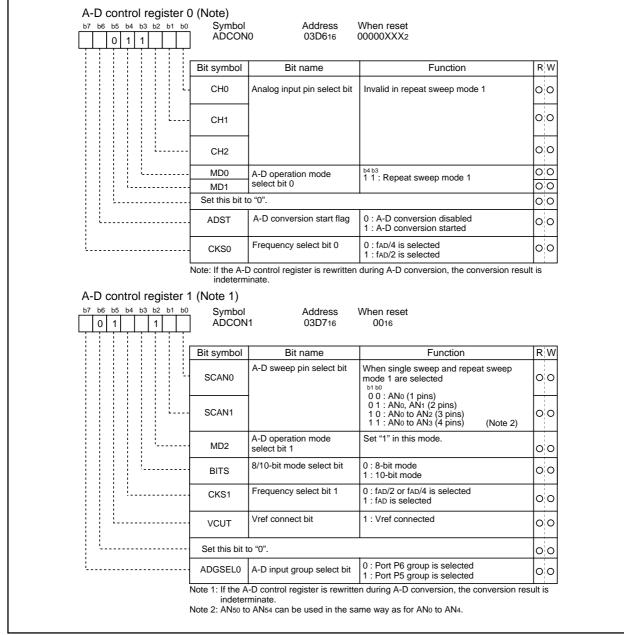

Figure 1.89. A-D conversion register in repeat sweep mode 1

# • Sample and hold

Sample and hold is selected by setting bit 0 of the A-D control register 2 (address 03D416) to "1". When sample and hold is selected, the rate of conversion of each pin increases. As a result, a 28  $\phi$ AD cycle is achieved with 8-bit resolution and 33  $\phi$ AD with 10-bit resolution. Sample and hold can be selected in all modes. However, in all modes, be sure to specify before starting A-D conversion whether sample and hold is to be used.

# **Programmable I/O Ports**

There are 43 programmable I/O ports: P0 to P7. Each port can be set independently for input or output using the direction register. A pull-up resistance for each block of 4 ports can be set. The port P1 allows the drive capacity of its N-channel output transistor to be set as necessary.

Figures 1.90 to 1.92 show the programmable I/O ports.

Each pin functions as a programmable I/O port and as the I/O for the built-in peripheral devices.

To use the pins as the inputs for the built-in peripheral devices, set the direction register of each pin to input mode. When the pins are used as the outputs for the built-in peripheral devices, they function as outputs regardless of the contents of the direction registers. See the descriptions of the respective functions for how to set up the built-in peripheral devices.

# (1) Direction registers

Figure 1.93 shows the direction registers.

These registers are used to choose the direction of the programmable I/O ports. Each bit in these registers corresponds one for one to each I/O pin.

# (2) Port registers

Figure 1.94 shows the port registers.

These registers are used to write and read data for input and output to and from an external device. A port register consists of a port latch to hold output data and a circuit to read the status of a pin. Each bit in port registers corresponds one for one to each I/O pin.

# (3) Pull-up control registers

Figure 1.95 shows the pull-up control registers.

The pull-up control register can be set to apply a pull-up resistance to each block of 4 ports. When ports are set to have a pull-up resistance, the pull-up resistance is connected only when the direction register is set for input.

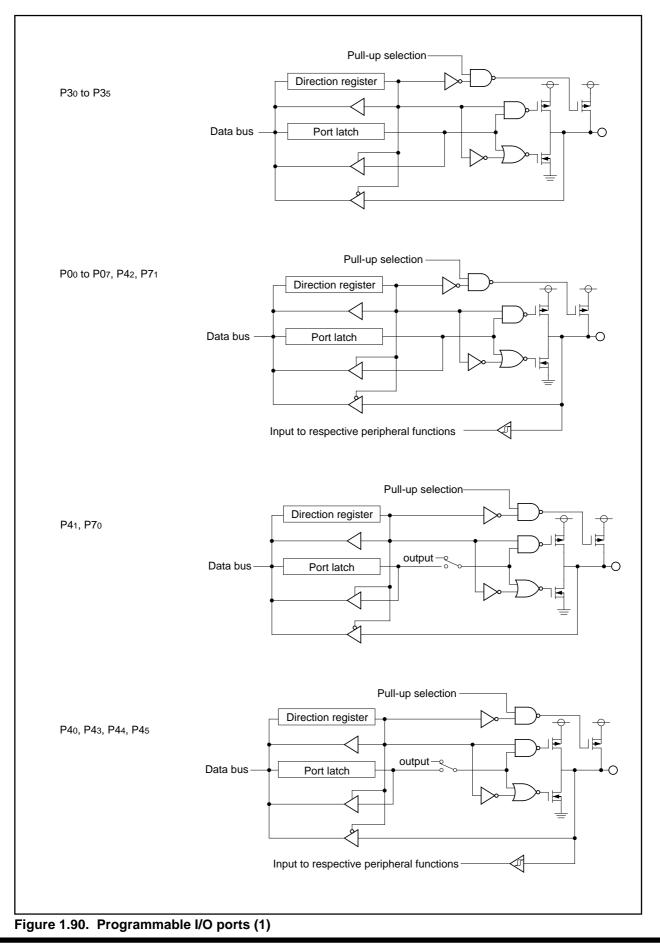

## (4) Port P1 drive capacity control register

Figure 1.95 shows a structure of the port P1 drive capacity control register.

This register is used to control the drive capacity of the port P1's N-channel output transistor. Each bit in this register corresponds one for one to the port pins.

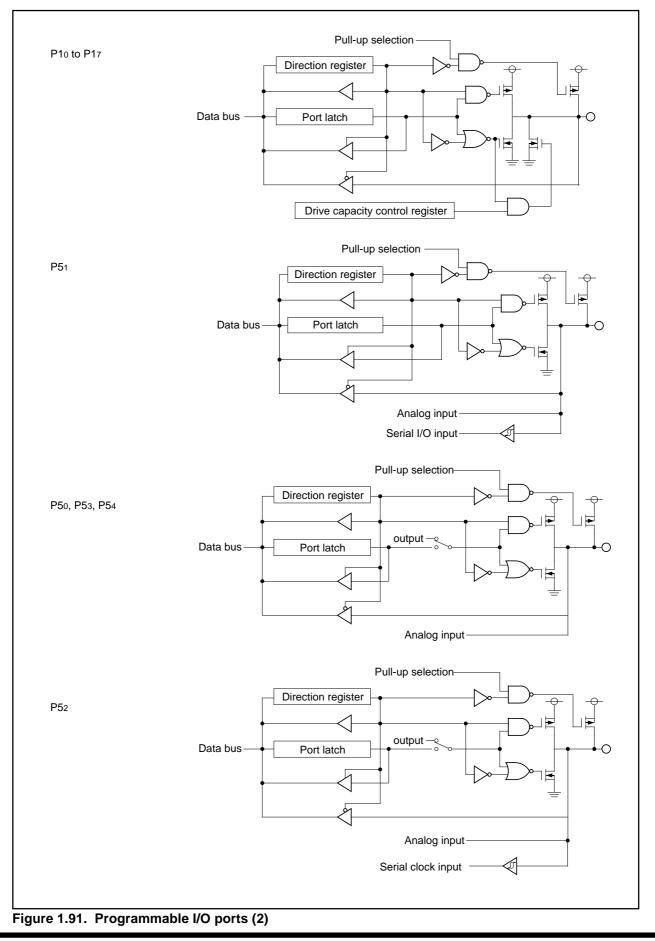

# Programmable I/O Port

# Programmable I/O Port

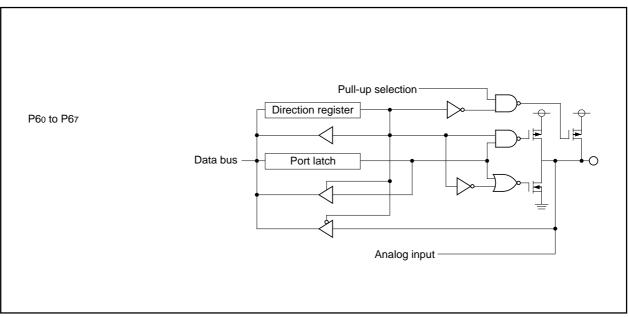

Figure 1.92. Programmable I/O ports (3)

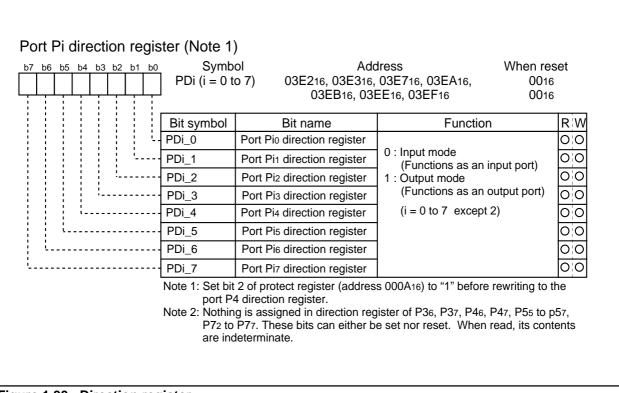

Figure 1.93. Direction register

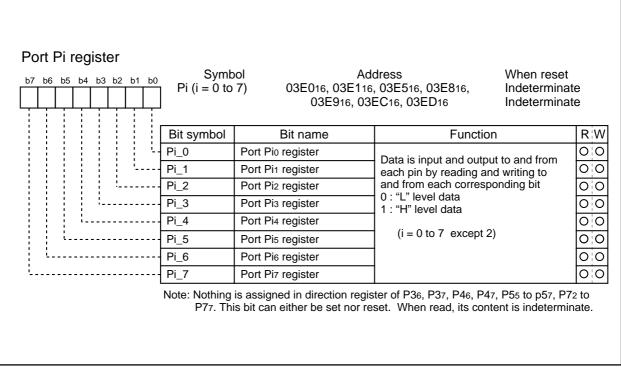

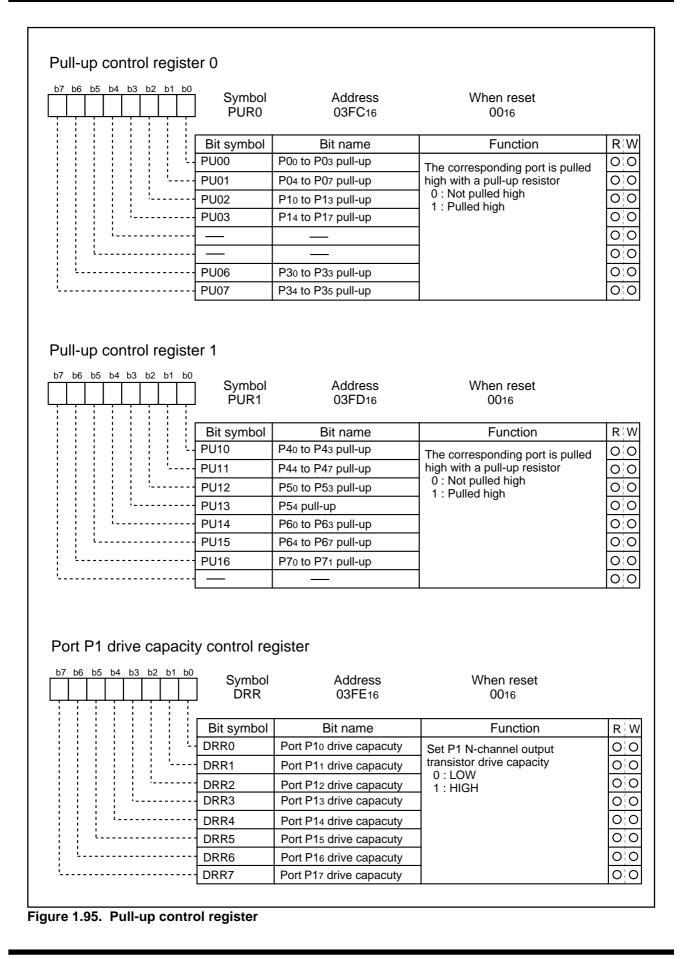

Figure 1.94. Port register

# Example connection of unused pins

Table 1.36.	Example	connection of	f unused pins
-------------	---------	---------------	---------------

Pin name	Connection
Ports P0, P1, P3 to P7	After setting for input mode, connect every pin to Vss (pull-down); or after setting for output mode, leave these pins open.
XOUT (Note)	Open
AVcc	Connect to Vcc
AVss, Vref	Connect to Vss

Note: With external clock input to XIN pin.

# **Usage Precaution**

## Timer A (timer mode)

(1) Reading the timer A0 register while a count is in progress allows reading, with arbitrary timing, the value of the counter. Reading the timer A0 register with the reload timing gets "FFFF16". Reading the timer A0 register after setting a value in the timer A0 register with a count halted but before the counter starts counting gets a proper value.

# Timer A (event counter mode)

- (1) Reading the timer A0 register while a count is in progress allows reading, with arbitrary timing, the value of the counter. Reading the timer A0 register with the reload timing gets "FFFF16" by underflow or "000016" by overflow. Reading the timer A0 register after setting a value in the timer A0 register with a count halted but before the counter starts counting gets a proper value.
- (2) When stop counting in free run type, set timer again.

# Timer A (one-shot timer mode)

- (1) Setting the count start flag to "0" while a count is in progress causes as follows:
  - The counter stops counting and a content of reload register is reloaded.
  - The TA0OUT pin outputs "L" level.
  - The interrupt request generated and the timer A0 interrupt request bit goes to "1".
- (2) The timer A0 interrupt request bit goes to "1" if the timer's operation mode is set using any of the following procedures:
  - Selecting one-shot timer mode after reset.
  - Changing operation mode from timer mode to one-shot timer mode.
  - Changing operation mode from event counter mode to one-shot timer mode.

Therefore, to use timer A0 interrupt (interrupt request bit), set timer A0 interrupt request bit to "0" after the above listed changes have been made.

## Timer A (pulse width modulation mode)

- (1) The timer A0 interrupt request bit becomes "1" if setting operation mode of the timer in compliance with any of the following procedures:
  - Selecting PWM mode after reset.
  - Changing operation mode from timer mode to PWM mode.
  - Changing operation mode from event counter mode to PWM mode.

Therefore, to use timer A0 interrupt (interrupt request bit), set timer A0 interrupt request bit to "0" after the above listed changes have been made.

(2) Setting the count start flag to "0" while PWM pulses are being output causes the counter to stop counting. If the TA00UT pin is outputting an "H" level in this instance, the output level goes to "L", and the timer A0 interrupt request bit goes to "1". If the TA00UT pin is outputting an "L" level in this instance, the level does not change, and the timer A0 interrupt request bit does not becomes "1".

#### Timer B (timer mode, event counter mode)

(1) Reading the timer Bi register while a count is in progress allows reading, with arbitrary timing, the value of the counter. Reading the timer Bi register with the reload timing gets "FFFF16". Reading the timer Bi register after setting a value in the timer Bi register with a count halted but before the counter starts counting gets a proper value.

#### Timer B (pulse period/pulse width measurement mode)

- (1) If changing the measurement mode select bit is set after a count is started, the timer Bi interrupt request bit goes to "1".
- (2) When the first effective edge is input after a count is started, an indeterminate value is transferred to the reload register. At this time, timer Bi interrupt request is not generated.

#### Timer X (timer mode)

(1) Reading the timer Xi register while a count is in progress allows reading, with arbitrary timing, the value of the counter. Reading the timer Xi register with the reload timing gets "FFFF16". Reading the timer A0 register after setting a value in the timer Xi register with a count halted but before the counter starts counting gets a proper value.

#### Timer X (event counter mode)

- (1) Reading the timer Xi register while a count is in progress allows reading, with arbitrary timing, the value of the counter. Reading the timer Xi register with the reload timing gets "FFFF16" by underflow or "000016" by overflow. Reading the timer Xi register after setting a value in the timer Xi register with a count halted but before the counter starts counting gets a proper value.
- (2) When stop counting in free run type, set timer again.

## Timer X (one-shot timer mode)

- (1) Setting the count start flag to "0" while a count is in progress causes as follows:
  - The counter stops counting and a content of reload register is reloaded.
  - The TXINOUT pin outputs "L" level.
  - The interrupt request generated and the timer Xi interrupt request bit goes to "1".
- (2) The timer Xi interrupt request bit goes to "1" if the timer's operation mode is set using any of the following procedures:
  - Selecting one-shot timer mode after reset.
  - Changing operation mode from timer mode to one-shot timer mode.
  - Changing operation mode from event counter mode to one-shot timer mode.

Therefore, to use timer Xi interrupt (interrupt request bit), set timer Xi interrupt request bit to "0" after the above listed changes have been made.

# Timer X (pulse width modulation mode)

- (1) The timer Xi interrupt request bit becomes "1" if setting operation mode of the timer in compliance with any of the following procedures:
  - Selecting PWM mode after reset.
  - Changing operation mode from timer mode to PWM mode.
  - Changing operation mode from event counter mode to PWM mode.

Therefore, to use timer Xi interrupt (interrupt request bit), set timer Xi interrupt request bit to "0" after the above listed changes have been made.

(2) Setting the count start flag to "0" while PWM pulses are being output causes the counter to stop counting. If the TXIINOUT pin is outputting an "H" level in this instance, the output level goes to "L", and the timer Xi interrupt request bit goes to "1". If the TXIINOUT pin is outputting an "L" level in this instance, the level does not change, and the timer Xi interrupt request bit does not becomes "1".

#### Timer X (pulse period/pulse width measurement mode)

- (1) If changing the measurement mode select bit is set after a count is started, the timer Xi interrupt request bit goes to "1".
- (2) When the first effective edge is input after a count is started, an indeterminate value is transferred to the reload register. At this time, timer Xi interrupt request is not generated.

## **A-D Converter**

- (1) Write to each bit (except bit 6) of A-D control register 0, to each bit of A-D control register 1, and to bit 0 of A-D control register 2 when A-D conversion is stopped (before a trigger occurs).
   In particular, when the Vref connection bit is changed from "0" to "1", start A-D conversion after an elapse of 1 µs or longer.
- (2) When changing A-D operation mode, select analog input pin again.
- (3) Using one-shot mode or single sweep mode

Read the correspondence A-D register after confirming A-D conversion is finished. (It is known by A-D conversion interrupt request bit.)

(4) Using repeat mode, repeat sweep mode 0 or repeat sweep mode 1 Use the undivided main clock as the internal CPU clock.

## Stop Mode and Wait Mode

- (1) When returning from stop mode by hardware reset, **RESET** pin must be set to "L" level until main clock oscillation is stabilized.
- (2) When shifting to WAIT mode or STOP mode, the program stops after reading 8 bytes from the WAIT instruction and the instruction that sets all clock stop bits to "1" in the instruction queue. Therefore, insert a minimum of 8 NOPs after the WAIT instruction and the instruction that sets all clock stop bits to "1".
- (3) When the MCU running in low-speed or low power dissipation mode, do not enter WAIT mode with WAIT peripheral function clock stop bit set to "1".

# Interrupts

- (1) Reading address 0000016
  - When maskable interrupt is occurred, CPU read the interrupt information (the interrupt number and interrupt request level) in the interrupt sequence.

The interrupt request bit of the certain interrupt written in address 0000016 will then be set to "0". Reading address 0000016 by software sets enabled highest priority interrupt source request bit to "0".

Though the interrupt is generated, the interrupt routine may not be executed.

Do not read address 0000016 by software.

- (2) Setting the stack pointer
  - The value of the stack pointer immediately after reset is initialized to 000016. Accepting an interrupt before setting a value in the stack pointer may become a factor of runaway. Be sure to set a value in the stack pointer before accepting an interrupt.

Concerning the first instruction immediately after reset, generating any interrupt is prohibited.

- (3) External interrupt
  - When changing a polarity of pins INT0 and INT1, the interrupt request bit may become "1". Clear the interrupt request bit after changing the polarity.
- (4) Changing interrupt control register

See "Changing Interrupt Control Register".

# **Electrical characteristics**

Symbol	Parameter	Condition	Rated value	Unit
Vcc	Supply voltage		- 0.3 to 6.5 (Note 1)	V
AVcc	Analog supply voltage		- 0.3 to 6.5 (Note 1)	V

f (Xin)	Main clock input oscill	lation	Mask ROM versio	on Vcc=4.0V to 5.5V	0		10	MH
,	frequency			Vcc=2.7V to 4.0V	0		5 x Vcc - 10.000	MH
			Flash memory ve	rsion Vcc=4.0V to 5.5V	0		10	MH
f (Xcin)	Subclock oscillation fr	requency				32.768	50	kHz

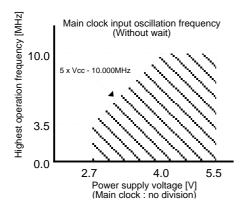

Table 1.37. Recommended operating conditions (Note 1)

Note 1: Unless otherwise noted: Vcc = 2.7V to 5.5V, Vss = 0V, Ta = - 20 to 85°C (Extended operating temperature version:- 40 to 85°C). Flash version: Vcc = 4.0V to 5.5V, Vss = 0V, Ta = - 20 to 85°C (Extended operating temperature version:- 40 to 85°C.) Note 2: The average output current is an average value measured over 100ms.

Note 3: Keep output current as follows:

The sum of port P3 and P4 IOL (peak) is under 40 mA. The sum of port P1 IOL (peak) is under 60 mA. The sum of port P1, P3 and P4 IOH (peak) is under 40 mA. The sum of port P0, P5, P6 and P7 IOL (peak) is under 80 mA. The sum of port P0, P5, P6 and P7 IOL (peak) is under 80 mA.

Note 4: Relationship between main clock oscillation frequency and supply voltage.

VCC = 5V

# **Outline Performance**

Table 1.74 shows the outline performance of the M30201 (flash memory version).

Item		Performance		
Power supply voltage		4.0V to 5.5 V (f(XIN)=10MHz)		
Program/erase voltage		VPP=12V ± 5% (f(XIN)=10MHz, Ta=25±5°C)		
		Vcc=5V ± 10% (f(XIN)=10MHz, Ta=25±5°C)		
Flash memory operation mode		Three modes (parallel I/O, standard serial I/O, CPU rewrite)		
Erase block	User ROM area	See Figure 1.96		
division	Boot ROM area	One division (3.5 Kbytes) (Note)		
Program method		In units of byte		
Erase method		Collective erase		
Program/erase control method		Program/erase control by software command		
Number of commands		6 commands		
Program/erase co	ount	100 times		
ROM code protec	t	Parallel I/O mode is supported.		

#### Table 1.74. Outline Performance of the M30201 (flash memory version)

Note: The boot ROM area contains a standard serial I/O mode control program which is stored in it when shipped from the factory. This area can be erased and programmed in only parallel I/O mode.

# **Flash Memory**

The M30201 (flash memory version) contains the NOR type of flash memory that requires a high-voltage VPP power supply for program/erase operations, in addition to the VCC power supply for device operation. For this flash memory, three flash memory modes are available in which to read, program, and erase: parallel I/O and standard serial I/O modes in which the flash memory can be manipulated using a programmer and a CPU rewrite mode in which the flash memory can be manipulated by the Central Processing Unit (CPU). Each mode is detailed in the pages to follow.

In addition to the ordinary user ROM area to store a microcomputer operation control program, the flash memory has a boot ROM area that is used to store a program to control rewriting in CPU rewrite and standard serial I/O modes. This boot ROM area has had a standard serial I/O mode control program stored in it when shipped from the factory. However, the user can write a rewrite control program in this area that suits the user's application system. This boot ROM area can be rewritten in only parallel I/O mode.

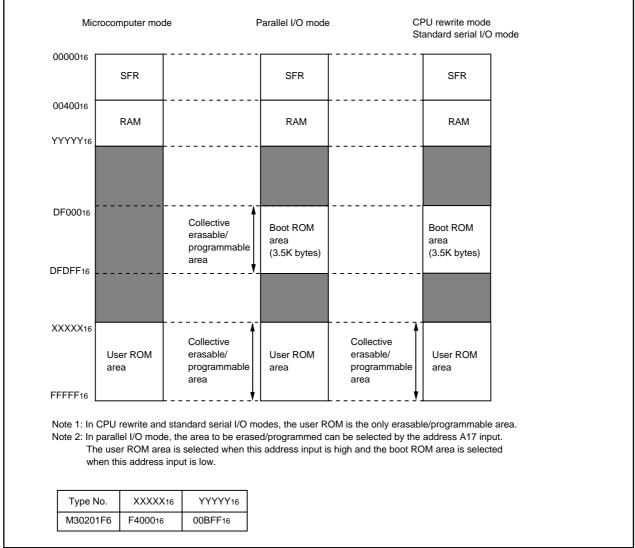

Figure 1.96. Block diagram of flash memory version

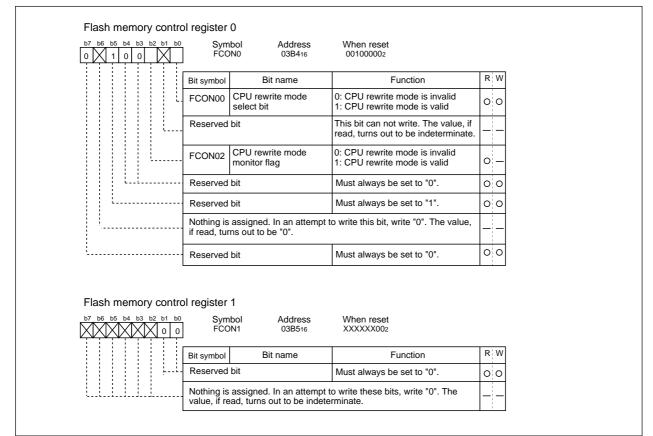

# **CPU Rewrite Mode**

In CPU rewrite mode, the on-chip flash memory can be operated on (read, program, or erase) under control of the Central Processing Unit (CPU). In CPU rewrite mode, the flash memory can be operated on by reading or writing to the flash memory control register and flash command register. Figure 1.97, Figure 1.98 show the flash memory control register, and flash command register respectively.

Also, in CPU rewrite mode, the CNVss pin is used as the VPP power supply pin. Apply the power supply voltage, VPPH, from an external source to this pin.

In CPU rewrite mode, only the user ROM area shown in Figure 1.96 can be rewritten; the boot ROM area cannot be rewritten. Make sure the program and block commands are issued for only the user ROM area. The control program for CPU rewrite mode can be stored in either user ROM or boot ROM area. In the CPU rewrite mode, because the flash memory cannot be read from the CPU, the rewrite control program must be transferred to internal RAM before it can be executed.

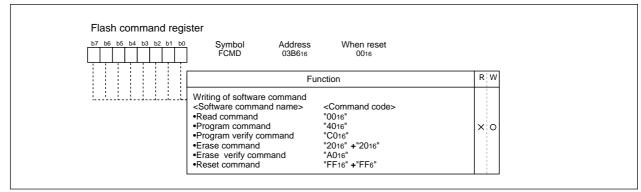

Figure 1.98. Flash command register

# **Microcomputer Mode and Boot Mode**

The control program for CPU rewrite mode must be written into the user ROM or boot ROM area in parallel I/O mode beforehand. (If the control program is written into the boot ROM area, the standard serial I/O mode becomes unusable.)

See Figure 1.96 for details about the boot ROM area.

Normal microcomputer mode is entered when the microcomputer is reset with pulling CNVss pin low (Vss). In this case, the CPU starts operating using the control program in the user ROM area.

When the microcomputer is reset by pulling the P52 pin high (VCC), the CNVss pin high(VPPH), the CPU starts operating using the control program in the boot ROM area. This mode is called the "boot" mode. The control program in the boot ROM area can also be used to rewrite the user ROM area.

## CPU rewrite mode operation procedure

The internal flash memory can be operated on to program, read, verify, or erase it while being placed onboard by writing commands from the CPU to the flash memory control register (addresses 03B416, 03B516) and flash command register (address 03B616). Note that when in CPU rewrite mode, the boot ROM area cannot be accessed for program, read, verify, or erase operations. Before this can be accomplished, a CPU write control program must be written into the boot ROM area in parallel input/output mode. The following shows a CPU rewrite mode operation procedure.

## <Start procedure (Note 1)>

- (1) Apply VPPH to the CNVss/VPP pin and VCC to the port P52 pin for reset release. Or the user can jump from the user ROM area to the boot ROM area using the JMP instruction and execute the CPU write control program. In this case, set the CPU write mode select bit of the flash memory control register to "1" before applying VPPH to the CNVss/VPP pin.
- (2) After transferring the CPU write control program from the boot ROM area to the internal RAM, jump to this control program in RAM. (The operations described below are controlled by this program.)
- (3) Set the CPU rewrite mode select bit to "1".
- (4) Read the CPU rewrite mode monitor flag to see that the CPU rewrite mode is enabled.
- (5) Execute operation on the flash memory by writing software commands to the flash command register.

Note 1: In addition to the above, various other operations need to be performed, such as for entering the data to be written to flash memory from an external source (e.g., serial I/O), initializing the ports, and writing to the watchdog timer.

## <Clearing procedure>

- (1) Apply Vss to the CNVss/VPP pin.
- (2) Set the CPU rewrite mode select bit to "0".

# **Precautions on CPU Rewrite Mode**

Described below are the precautions to be observed when rewriting the flash memory in CPU rewrite mode.

#### (1) Operation speed

During erase/program mode, set BCLK to 5 MHz or less by changing the divide ratio.

#### (2) Instructions inhibited against use

The instructions listed below cannot be used during CPU rewrite mode because they refer to the internal data of the flash memory:

UND instruction, INTO instruction, JMPS instruction, JSRS instruction, and BRK instruction

#### (3) Interrupts inhibited against use

No interrupts can be used that look up the fixed vector table in the flash memory area. Maskable interrupts may be used by setting the interrupt vector table in a location outside the flash memory area.

# **Software Commands**

Table 1.75 lists the software commands available with the M30201 (flash memory version). When CPU rewrite mode is enabled, write software commands to the flash command register to specify the operation to erase or program.

The content of each software command is explained below.

	F	irst bus cyc	le	Second bus cycle		
Command	Mode	Address	Data (Do to D7)	Mode	Address	Data (Do to D7)
Read	Write	03B616	0016			
Program	Write	03B616	4016	Write	Program address	Program data
Program verify	Write	03B616	C016	Read	Verify address	Verify data
Erase	Write	03B616	2016	Write	03B616	2016
Erase verify	Write	03B616	A016	Read	Verify address	Verify data
Reset	Write	03B616	FF16	Write	03B616	FF16

#### Read Command (0016)

The read mode is entered by writing the command code "0016" to the flash command register in the first bus cycle. When an address to be read is input in one of the bus cycles that follow, the content of the specified address is read out at the data bus (D0–D7), 8 bits at a time.

The read mode is retained intact until another command is written.

After reset and after the reset command is executed, the read mode is set.

## Program Command (4016)

The program mode is entered by writing the command code "4016" to the flash command register in the first bus cycle. When the user execute an instruction to write byte data to the desired address (e.g., STE instruction) in the second bus cycle, the flash memory control circuit executes the program operation. The program operation requires approximately 20  $\mu$ s. Wait for 20  $\mu$ s or more before the user go to the next processing.

During program operation, the watchdog timer remains idle, with the value "7FFF16" set in it.

Note 1: The write operation is not completed immediately by writing a program command once. The user must always execute a program-verify command after each program command executed. And if verification fails, the user need to execute the program command repeatedly until the verification passes. See Figure 1.99 for an example of a programming flowchart.

## Program-verify command (C016)

The program-verify mode is entered by writing the command code "C016" to the flash command register in the first bus cycle. When the user execute an instruction (e.g., LDE instruction) to read byte data from the address to be verified (the previously programmed address) in the second bus cycle, the content that has actually been written to the address is read out from the memory.

The CPU compares this read data with the data that it previously wrote to the address using the program command. If the compared data do not match, the user need to execute the program and program-verify operations one more time.

#### Erase command (2016 + 2016)

The flash memory control circuit executes an erase operation by writing command code "2016" to the flash command register in the first bus cycle and the same command code to the flash command register again in the second bus cycle. The erase operation requires approximately 20 ms. Wait for 20 ms or more before the user go to the next processing.

Before this erase command can be performed, all memory locations to be erased must have had data "0016" written to by using the program and program-verify commands. During erase operation, the watchdog timer remains idle, with the value "7FFF16 set in it.

Note 1: The erase operation is not completed immediately by writing an erase command once. The user must always execute an erase-verify command after each erase command executed. And if verification fails, the user need to execute the erase command repeatedly until the verification passes. See Figure 1.99 for an example of an erase flowchart.

#### Erase-verify command (A016)

The erase-verify mode is entered by writing the command code "A016" to the flash command register in the first bus cycle. When the user execute an instruction to read byte data from the address to be verified (e.g., LDE instruction) in the second bus cycle, the content of the address is read out.

The CPU must sequentially erase-verify memory contents one address at a time, over the entire area erased. If any address is encountered whose content is not "FF16" (not erased), the CPU must stop erase-verify at that point and execute erase and erase-verify operations one more time.

Note 1: If any unerased memory location is encountered during erase-verify operation, be sure to execute erase and erase-verify operations one more time. In this case, however, the user does not need to write data "0016" to memory before erasing.

## Reset command (FF16 + FF16)

The reset command is used to stop the program command or the erase command in the middle of operation. After writing command code "4016" or "2016" twice to the flash command register, write command code "FF16" to the flash command register in the first bus cycle and the same command code to the flash command register again in the second bus cycle. The program command or erase command is disabled, with the flash memory placed in read mode.

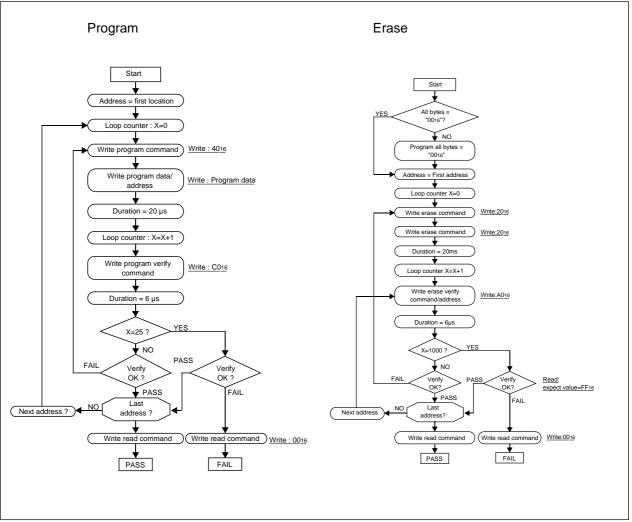

Figure 1.99. Program and erase execution flowchart in the CPU rewrite mode

Pin name	Signal name	I/O	Function
Vcc,Vss	Power supply input		Apply 5 V $\pm$ 10 % to the Vcc pin and 0 V to the Vss pin.
CNVss	CNVss	Ι	Apply 12 V $\pm$ 5 % to the CNVss pin.
RESET	Reset input	Ι	Connect this pin to Vss.
Xin	Clock input	Ι	Connect a ceramic or crystal resonator between the XIN and XOUT pins.
Хоит	Clock output	0	When entering an externally derived clock, enter it from XIN and leave XOUT open.
AVcc, AVss	Analog power supply input		Connect AVss to Vss and AVcc to Vcc, respectively.
Vref	Reference voltage input	I	Connect this pin to Vss.
P00 to P07	Data I/O Do to D7	I/O	These are data Do-D7 input/output pins.
P10 to P17	Address input A8 to A15	I	These are address A8–A15 input pins.
P30 to P33	Address input A4 to A7	Ι	These are address A4–A7 input pins.
P34 to P35	Input port P3	Ι	Enter low signals to these pins.
P40	WE input	Ι	This is a $\overline{WE}$ input pin.
P41	OE input	Ι	This is a $\overline{OE}$ input pin.
P43	CE input	I	This is a $\overline{CE}$ input pin.
P42, P44, P45	Input port P4	I	Enter high signals or low signals to these pins.
P50	Address input A17	Ι	This is address A17 input pin.
P51	VRFY input	I	Apply VIH (5 V) to this pin when VPP = VPPH (12 V), or VIL (0 V) when VPP = VPPL (5 V).
P52	Input port P5	Ι	Enter low signal to this pin.
P53, P54	Input port P5	I	Enter high signals or low signals to these pins.
P60 to P63	Address input A0 to A3	I	These are address A0-A3 input pins.
P64 to P67	Input port P6	I	Enter high signals or low signals to these pins.
P70 to P71	Input port P7	Ι	Enter high signals or low signals to these pins.

# Description of Pin Function (Flash Memory Parallel I/O Mode)

# Parallel I/O Mode

The parallel I/O mode is entered by making connections shown in Figures 1.101 and 1.102 and then turning the VPPH power supply on. In this mode, the M30201 (flash memory version) operates in a manner similar to the NOR flash memory M5M28F101 from Mitsubishi. Note, however, that there are some differences with regard to the functions not available with the microcomputer (function of read device identification code) and matters related to memory capacity.

Table 1.76 shows pin relationship between the M30201 and M5M28F101 in parallel I/O mode.

	M30201(flash memory version)	M5M28F101
Vcc	Vcc	Vcc
Vss	Vss	Vss
Address input	P60 to P63, P30 to P33, P10 to P17, P50	A0 to A15, A17
Data I/O	P00 to P07	Do to D7
OE input	P41	OE
CE input	P43	CE
WE input	P40	WE
VRFY input (Note)	P51	

Table 1.76.	Pin	relationship	in	parallel I/O mode
		relationship		

Note: The VRFY input only selects read-only or read/write mode, and does not have any pin associated with it on the M5M28F101.

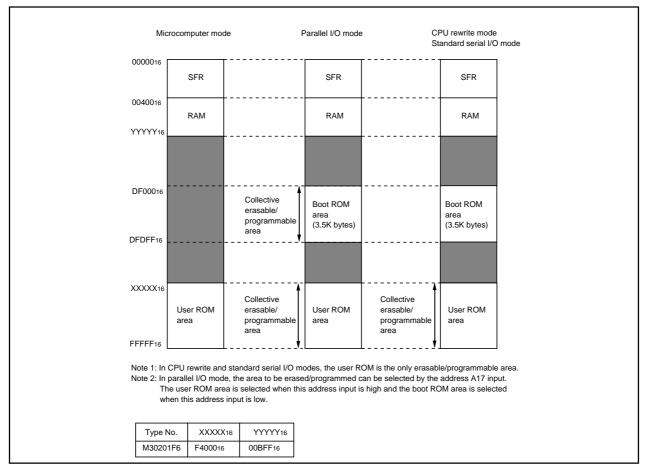

Figure 1.100. Block diagram of flash memory version

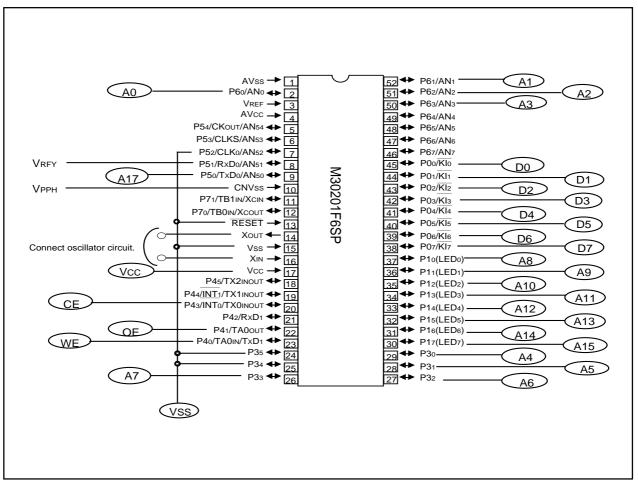

Figure 1.101. Pin connection diagram in parallel I/O mode (1)

# Appendix Parallel I/O Mode (Flash memory version)

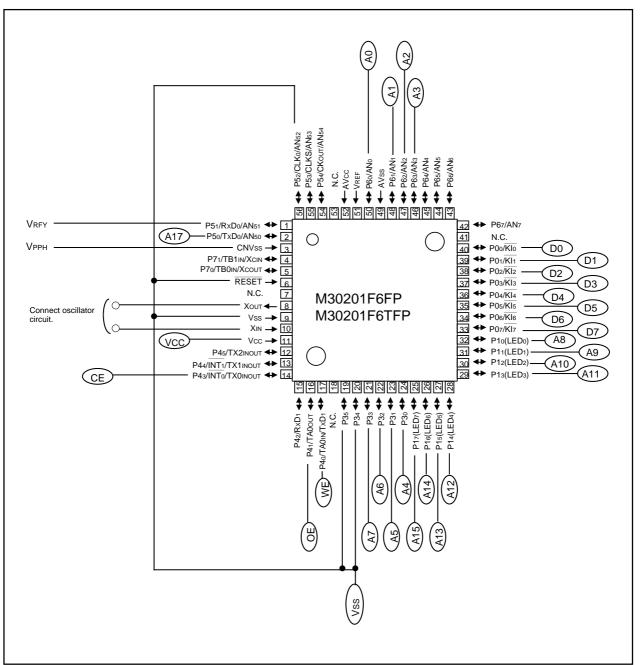

Figure 1.102. Pin connection diagram in parallel I/O mode (2)

# **User ROM and Boot ROM Areas**

In parallel I/O mode, the user ROM and boot ROM areas shown in Figure 1.100 can be rewritten. In the boot ROM area, an erase block operation is applied to only one 3.5 K byte block. The boot ROM area has had a standard serial I/O mode control program stored in it when shipped from the Mitsubishi factory. Therefore, using the device in standard serial input/output mode, the user does not need to write to the boot ROM area.

# Functional Outline (Parallel I/O Mode)

In parallel I/O mode, bus operation modes—Read, Output Disable, Standby, and Write—are selected by the status of the  $\overline{CE}$ ,  $\overline{OE}$ ,  $\overline{WE}$ , VRFY, and CNVSS input pins.

The contents of erase, program, and other operations are selected by writing a software command. The data in memory can only be read out by a read after software command input.

Program and erase operations are controlled using software commands.

Mode	Pin name	CE	ŌĒ	WE	Vrfy	Vpp	Do to D7
Deed	Read	VIL	VIL	Vін	VIL	Vpph	Data output
Read only	Output disabled	VIL	Vін	Vін	VIL	Vpph	Hi-Z
	Stand by	Vін	Х	Х	VIL	Vpph	Hi-Z
Read/ Write	Read	VIL	VIL	Vін	Vін	Vpph	Data output
	Output disabled	VIL	Vін	Vін	Vін	Vpph	Hi-Z
	Stand by	Vін	Х	Х	Vін	Vpph	Hi-Z
	Write	VIL	Vih	VIL	Vін	Vpph	Data input

Table 1.77. Relationship between control signals and bus operation modes

Note: X can be VIL or VIH.

The following explains about bus operation modes, software commands, and status register.

# **Bus Operation Modes**

Read-only mode is entered by applying VPPH to the CNVss pin and a low voltage to the VRFY pin. Read-only mode has three states: Read, Output Disable, and Standby which are selected by setting the  $\overline{CE}$ ,  $\overline{OE}$ , and  $\overline{WE}$  pins high or low.

Read-write mode is entered by applying VPPH to the CNVSS pin and a high voltage to the VRFY pin. Read-write mode has four states: Read, Output Disable, Standby, and Write which are selected by setting the  $\overline{CE}$ ,  $\overline{OE}$ , and  $\overline{WE}$  pins high or low.

#### Read

The Read mode is entered by pulling the  $\overline{WE}$  pin high when the  $\overline{CE}$  and  $\overline{OE}$  pins are low. In Read mode, the data corresponding to each software command entered is output from the data I/O pins D0–D7.

#### **Output Disable**

The Output Disable mode is entered by pulling the  $\overline{CE}$  pin low and the  $\overline{WE}$  and  $\overline{OE}$  pins high. Also, the data I/O pins are placed in the high-impedance state.

#### Standby

The Standby mode is entered by driving the  $\overline{CE}$  pin high. Also, the data I/O pins are placed in the high-impedance state.

#### Write

The Write mode is entered by applying VPPH to the CNVSS pin and a high voltage to the VRFY pin and then pulling the  $\overline{WE}$  pin low when the  $\overline{CE}$  pin is low and  $\overline{OE}$  pin is high. In this mode, the device accepts the software commands or write data entered from the data I/O pins. A program, erase, or some other operation is initiated depending on the content of the software command entered here. The input data such as address is latched at the falling edge of  $\overline{WE}$  pin. The input data such as software command is latched at the rising edge of  $\overline{WE}$  pin.

# **Software Commands**

Table 1.78 lists the software commands available with the M30201 (flash memory version). By entering a software command from the data I/O pins (D0–D7) in Write mode, specify the content of the operation, such as erase or program operation, to be performed.

The following explains the content of each software command.

	F	First bus cyc	le	Second bus cycle		
Command	Mode	Address	Data (Do to D7)	Mode	Address	Data (Do to D7)
Read	Write	x	0016			
Program	Write	x	4016	Write	Program address	Program data
Program verify	Write	x	C016	Read	х	Verify data
Erase	Write	х	2016	Write	х	2016
Erase verify	Write	Verify address	A016	Read	х	Verify data
Reset	Write	x	FF16	Write	х	FF16

#### Table 1.78. Software command list (parallel I/O mode)

## Read Command (0016)

The read mode is entered by writing the command code "0016" in the first bus cycle. When an address to be read is input in one of the bus cycles that follow, the content of the specified address is read out at the data I/O pins (D0–D7).

The read mode is retained intact until another command is written.

After reset and after the reset command is executed, the read mode is set.

## Program Command (4016)

The program mode is entered by writing the command code "4016" in the first bus cycle. When an address and data to be program is write in the second bus cycle, the flash memory control circuit executes the program operation. The program operation requires approximately 20  $\mu$ s. Wait for 20  $\mu$ s or more before the user go to the next processing.

Note 1: The write operation is not completed immediately by writing a program command once. The user must always execute a program-verify command after each program command executed. And if verification fails, the user need to execute the program command repeatedly until the verification passes. See Figure 1.103 for an example of a programming flowchart.

# Program-verify command (C016)

The program-verify mode is entered by writing the command code "C016" in the first bus cycle and the verify data is output from the data I/O pins (D0–D7) in the second bus cycle.

#### Erase command (2016 + 2016)

The flash memory control circuit executes an erase operation by writing command code "2016" in the first bus cycle and the same command code again in the second bus cycle. The erase operation requires approximately 20 ms. Wait for 20 ms or more before the user go to the next processing. Before this erase command can be performed, all memory locations to be erased must have had data "0016" written to by using the program and program-verify commands.

Note 1: The erase operation is not completed immediately by writing an erase command once. The user must always execute an erase-verify command after each erase command executed. And if verification fails, the user need to execute the erase command repeatedly until the verification passes. See Figure 1.103 for an example of an erase flowchart.

## Erase-verify command (A016)

The erase-verify mode is entered by writing the command code "A016" in the first bus cycle and the verify data is output from the data I/O pins (D0–D7) in the second bus cycle.

Note 1: If any unerased memory location is encountered during erase-verify operation, be sure to execute erase and erase-verify operations one more time. In this case, however, the user does not need to write data "0016" to memory before erasing.

#### Reset command (FF16 + FF16)

The reset command is used to stop the program command or the erase command in the middle of operation. After writing command code "4016" or "2016" twice, write command code "FF16" in the first bus cycle and the same command code again in the second bus cycle. The program command or erase command is disabled, with the flash memory placed in read mode.

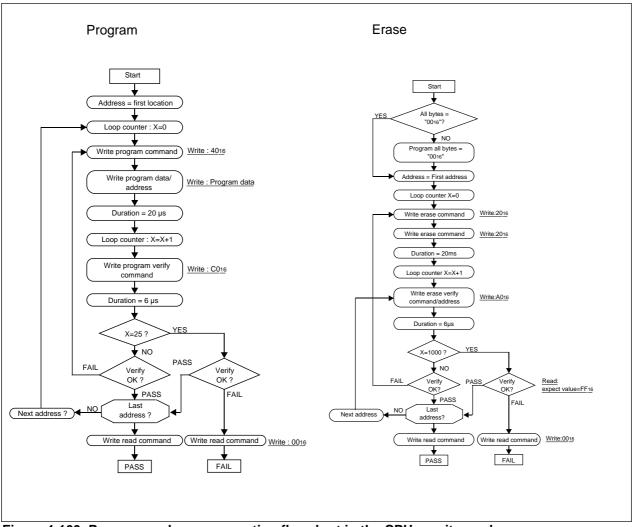

Figure 1.103. Program and erase execution flowchart in the CPU rewrite mode

# **Protect function**

In parallel I/O mode, the internal flash memory has the "protect function" available. This function protects the flash memory contents from being read or rewritten easily.

Depending on the content at the protect control address (FFFF16) in parallel I/O mode, this function inhibits the flash memory contents against read or modification. The protect control address (FFFF16) is shown in Figure 1.104. (This address exists in the user ROM area.)

The protect function is enabled by setting one of the two protect set bits to "0", so that the internal flash memory contents are inhibited against read or modification. The protect function is disabled by setting both of the two protect reset bits to "00", so that the internal flash memory contents can be read or modified. Once the protect function is set, the user cannot change settings of the protect clear bits while in parallel I/O mode. Settings of the protect reset bits can only be changed in CPU rewrite mode.

AVcc, AVss	Analog power supply input		Connect AVss to Vss and AVcc to Vcc, respectively.	
Vref	Reference voltage input	I	Enter the reference voltage for AD from this pin.	
P00 to P07	Input port P0	I	Input "H" or "L" level signal or open.	
P10 to P17	Input port P1	I	Input "H" or "L" level signal or open.	
P30 to P35	Input port P3	I	Input "H" or "L" level signal or open.	
P40 to P45	Input port P4	I	Input "H" or "L" level signal or open.	
P54	Input port P5	I	Input "H" or "L" level signal or open.	
P50	TxD output	0	Serial data output pin.	
P51	RxD input	1	Serial data input pin.	
P52	SCLK input	I	Mode entry pin. Supply "H" level when powering on MCU. When startup is completed this pin serves the serial input clock.	
P53	BUSY	I ->0	<ul> <li>This pin sets the type of serial flash programming mode.</li> <li>An "H" level input (mode 1) sets the mode to clock synchronous.</li> <li>An "L" level input (mode 2) sets the mode to clock asynchronous.</li> <li>This pin changes to "output" after entry into standard serial I/O mode.</li> </ul>	
P60 to P67	Input port P6	I	Input "H" or "L" level signal or open.	
P70 to P71	Input port P7	I	Input "H" or "L" level signal or open.	

#### Pin functions (Flash memory standard serial I/O mode)

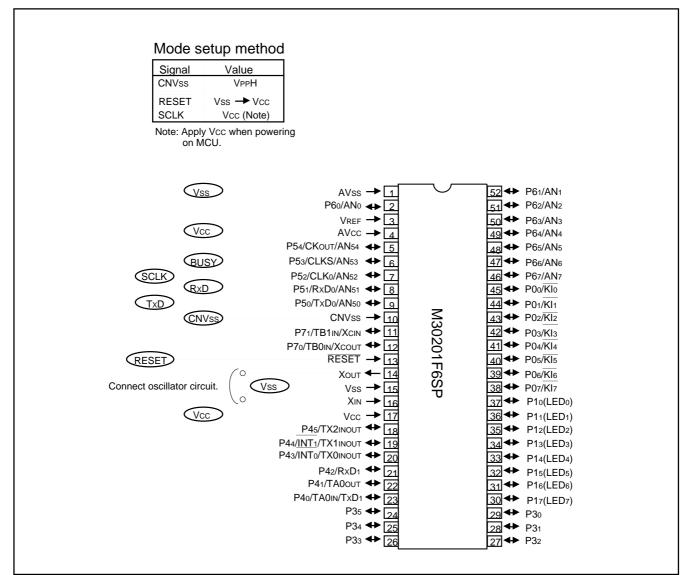

Figure 1.105. Pin connections for standard serial I/O mode (1)

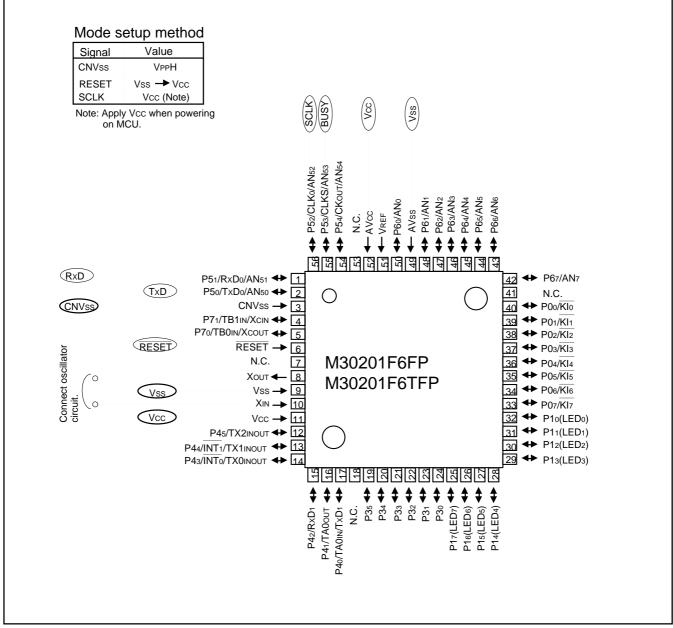

Figure 1.106. Pin connections for serial I/O mode (2)

# Standard serial I/O mode

The standard serial I/O mode inputs and outputs the software commands, addresses and data needed to operate (read, program, erase, etc.) the internal flash memory. This I/O is serial. There are actually two standard serial I/O modes: mode 1, which is clock synchronized, and mode 2, which is asynchronized. Both modes require a purpose-specific peripheral unit.

The standard serial I/O mode is different from the parallel I/O mode in that the CPU controls flash memory rewrite (uses the CPU's rewrite mode), rewrite data input and so forth. It is started when the reset is released, which is done when the P52 (SCLK) pin is "H" level, the CNVss pin "VppH" level. (In the ordinary command mode, set CNVss pin to "L" level.)

This control program is written in the boot ROM area when the product is shipped from Mitsubishi. Accordingly, make note of the fact that the standard serial I/O mode cannot be used if the boot ROM area is rewritten in the parallel I/O mode. Figures 1.105 and 1.106 show the pin connections for the standard serial I/O mode. Serial data I/O uses UART0 and transfers the data serially in 8-bit units. Standard serial I/O switches between mode 1 (clock synchronized) and mode 2 (clock asynchronized) according to the level of P53 (BUSY) pin when the reset is released.

To use standard serial I/O mode 1 (clock synchronized), set the P53 (BUSY) pin to "H" level and release the reset. The operation uses the four UART0 pins CLK0, RxD0, TxD0 and P53 (BUSY). The CLK0 pin is the transfer clock input pin through which an external transfer clock is input. The TxD0 pin is for CMOS output. The P53 (BUSY) pin outputs an "L" level when ready for reception and an "H" level when reception starts.

To use standard serial I/O mode 2 (clock asynchronized), set the P53 (BUSY) pin to "L" level and release the reset. The operation uses the two UART0 pins RxD0 and TxD0.

In the standard serial I/O mode, only the user ROM area indicated in Figure 1.96 can be rewritten. The boot ROM cannot.

In the standard serial I/O mode, a 7-byte ID code is used. When there is data in the flash memory, commands sent from the peripheral unit are not accepted unless the ID code matches.

# Overview of standard serial I/O mode 1 (clock synchronized)

In standard serial I/O mode 1, software commands, addresses and data are input and output between the MCU and peripheral units (serial programer, etc.) using clock-synchronized serial I/O (UART0) and P53 (BUSY). Standard serial I/O mode 1 is engaged by releasing the reset with the P53 (BUSY) pin "H" level. In reception, software commands, addresses and program data are synchronized with the rise of the transfer clock that is input to the CLK0 pin, and are then input to the MCU via the RxD0 pin. In transmission, the read data and status are synchronized with the fall of the transfer clock, and output from the TxD0 pin.

The TxDo pin is for CMOS output. Transfer is in 8-bit units with LSB first.

When busy, such as during transmission, reception, erasing or program execution, the P53 (BUSY) pin is "H" level. Accordingly, always start the next transfer after the P53 (BUSY) pin is "L" level.

Also, data and status registers in memory can be read after inputting software commands. Status, such as the operating state of the flash memory or whether a program or erase operation ended successfully or not, can be checked by reading the status register. Here following are explained software commands, status registers, etc.

# **Software Commands**

Table 1.79 lists software commands. In the standard serial I/O mode 1, erase operations, programs and reading are controlled by transferring software commands via the RxD0 pin. Software commands are explained here below.

	Control command		2nd byte	3rd byte	4th byte	5th byte	6th byte		When ID is not verificate
1	Page read	FF <sub>16</sub>	Address	Address	Data	Data	Data	Data	Not
	0		(middle)	(high)	output	output	output	output to	acceptable
								259th byte	·
2	Page program	4116	Address	Address	Data	Data	Data	Data	Not
			(middle)	(high)	input	input	input	input to	acceptable
								259th byte	
3	Erase all unlocked blocks	A716	D016						Not
									acceptable
4	Read status register	7016	SRD	SRD1					Acceptable
			output	output					
5	Clear status register	5016							Not
									acceptable
6	Read lockbit status	7116	Address	Address	Lock bit				Not
			(middle)	(high)	data				acceptable
					output				
7	ID check function	F5 <sub>16</sub>	Address	Address	Address	ID size	ID1	To ID7	Acceptable
			(low)	(middle)	(high)				
8	Download function	FA <sub>16</sub>	Size	Size	Check-	Data	То		Not
			(low)	(high)	sum	input	required		acceptable
							number		
							of times		
9	Version data output function	FB <sub>16</sub>	Version	Version	Version	Version	Version	Version	Acceptable
			data	data	data	data	data	data output	
			output	output	output	output	output	to 9th byte	
10	Boot area output function	FC <sub>16</sub>	Address	Address	Data	Data	Data	Data	Not
			(middle)	(high)	output	output	output	output to	acceptable
								259th byte	

Note 1: Shading indicates transfer from flash memory microcomputer to peripheral unit. All other data is transferred from the peripheral unit to the flash memory microcomputer.

Note 2: SRD refers to status register data. SRD1 refers to status register 1 data.

Note 3: All commands can be accepted when the flash memory is totally blank.

# Page Read Command

This command reads the specified page (256 bytes) in the flash memory sequentially one byte at a time. Execute the page read command as explained here following.

- (1) Transfer the "FF16" command code with the 1st byte.
- (2) Transfer addresses A8 to A15 and A16 to A23 with the 2nd and 3rd bytes respectively.
- (3) From the 4th byte onward, data (D0–D7) for the page (256 bytes) specified with addresses A8 to A23 will be output sequentially from the smallest address first in sync with the rise of the clock.

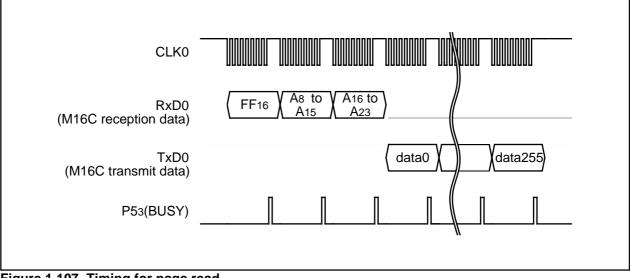

Figure 1.107. Timing for page read

### **Read Status Register Command**

This command reads status information. When the "7016" command code is sent with the 1st byte, the contents of the status register (SRD) specified with the 2nd byte and the contents of status register 1 (SRD1) specified with the 3rd byte are read.

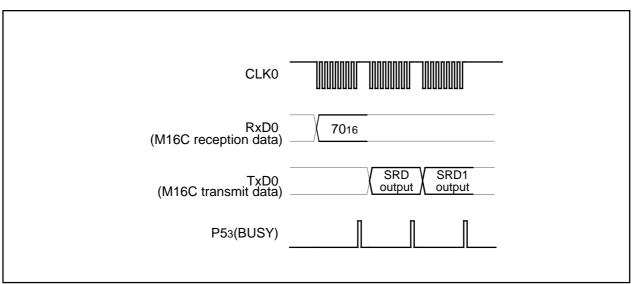

Figure 1.108. Timing for reading the status register

## **Clear Status Register Command**

This command clears the bits (SR3–SR4) which are set when the status register operation ends in error. When the "5016" command code is sent with the 1st byte, the aforementioned bits are cleared. When the clear status register operation ends, the P53 (BUSY) signal changes from the "H" to the "L" level.

CLK0	
RxD0 (M16C reception data)	5016
TxD0 (M16C transmit data)	
P53(BUSY)	

Figure 1.109. Timing for clearing the status register

## Page Program Command

This command writes the specified page (256 bytes) in the flash memory sequentially one byte at a time. Execute the page program command as explained here following.

- (1) Transfer the "4116" command code with the 1st byte.
- (2) Transfer addresses A8 to A15 and A16 to A23 with the 2nd and 3rd bytes respectively.
- (3) From the 4th byte onward, as write data (D0–D7) for the page (256 bytes) specified with addresses A8 to A23 is input sequentially from the smallest address first, that page is automatically written.

When reception setup for the next 256 bytes ends, the P53 (BUSY) signal changes from the "H" to the "L" level. The result of the page program can be known by reading the status register. For more information, see the section on the status register.

CLK0	
RxD0 (M16C reception data)	$ \begin{array}{c c} 4116 \\ \begin{array}{c} A8 \\ A15 \\ \end{array} \\ \begin{array}{c} A16 \\ A23 \\ \end{array} \\ \begin{array}{c} Aata0 \\ Aata0 \\ \end{array} \\ \begin{array}{c} Aata255 \\ Aata255 \\ \end{array} $
TxD0 (M16C transmit data)	
P53(BUSY) -	

Figure 1.110. Timing for the page program

#### Erase All Unlocked Blocks Command

This command erases the content of all blocks. Execute the erase all unlocked blocks command as explained here following.

(1) Transfer the "A716" command code with the 1st byte.

(2) Transfer the verify command code "D016" with the 2nd byte. With the verify command code, the erase operation will start and continue for all blocks in the flash memory.

When block erasing ends, the P53 (BUSY) signal changes from the "H" to the "L" level. The result of the erase operation can be known by reading the status register.

- CLK0	
RxD0 (M16C reception data)	A716 D016
TxD0 (M16C transmit data)	
P53(BUSY) _	

Figure 1.111. Timing for erasing all unlocked blocks

### **Read Lock Bit Status Command**

This command reads the lock bit status of the specified block. Execute the read lock bit status command as explained here following.

- (1) Transfer the "7116" command code with the 1st byte.
- (2) Transfer addresses A8 to A15 and A16 to A23 with the 2nd and 3rd bytes respectively.
- (3) The lock bit data of the specified block is output with the 4th byte. Write the highest address of the specified block for addresses A8 to A23.

The M30201 (flash memory version) does not have the lock bit, so the read value is always "1" (block unlock).

CLK0	
RxD0 (M16C reception data)	$\left(\begin{array}{c} 7116 \\ A15 \\ A15 \\ A23 \end{array}\right) A16 to A23$
TxD0 (M16C transmit data)	DQ6
P53(BUSY)	
Figure 1.112. Timing for reading lock bit s	status

## **Download Command**

This command downloads a program to the RAM for execution. Execute the download command as explained here following.

- (1) Transfer the "FA16" command code with the 1st byte.
- (2) Transfer the program size with the 2nd and 3rd bytes.
- (3) Transfer the check sum with the 4th byte. The check sum is added to all data sent with the 5th byte onward.
- (4) The program to execute is sent with the 5th byte onward.

When all data has been transmitted, if the check sum matches, the downloaded program is executed. The size of the program will vary according to the internal RAM.

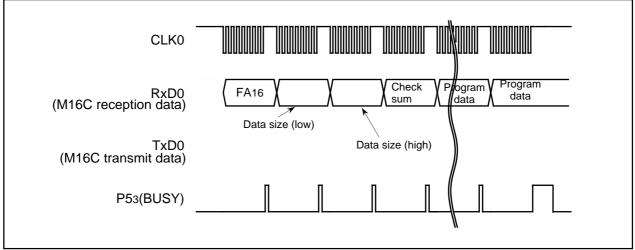

Figure 1.113. Timing for download

### **Version Information Output Command**

This command outputs the version information of the control program stored in the boot area. Execute the version information output command as explained here following.

- (1) Transfer the "FB16" command code with the 1st byte.
- (2) The version information will be output from the 2nd byte onward. This data is composed of 8 ASCII code characters.

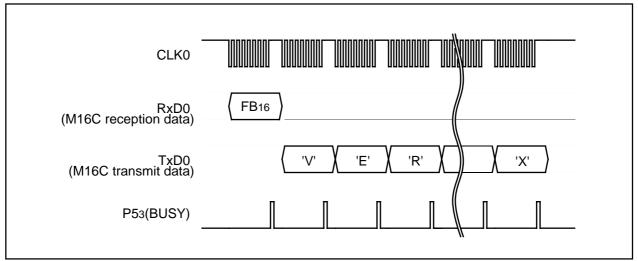

Figure 1.114. Timing for version information output

### **Boot ROM Area Output Command**

This command outputs the control program stored in the boot ROM area in one page blocks (256 bytes). Execute the boot ROM area output command as explained here following.

- (1) Transfer the "FC16" command code with the 1st byte.
- (2) Transfer addresses A8 to A15 and A16 to A23 with the 2nd and 3rd bytes respectively.
- (3) From the 4th byte onward, data (D0–D7) for the page (256 bytes) specified with addresses A8 to A23 will be output sequentially from the smallest address first, in sync with the fall of the clock.

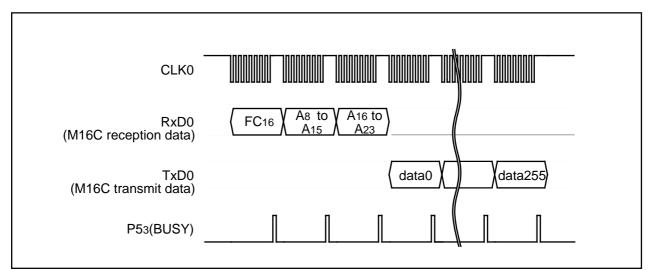

Figure 1.115. Timing for boot ROM area output

# ID Check

This command checks the ID code. Execute the boot ID check command as explained here following.

- (1) Transfer the "F516" command code with the 1st byte.
- (2) Transfer addresses A0 to A7, A8 to A15 and A16 to A23 of the 1st byte of the ID code with the 2nd, 3rd and 4th bytes respectively.
- (3) Transfer the number of data sets of the ID code with the 5th byte.
- (4) The ID code is sent with the 6th byte onward, starting with the 1st byte of the code.

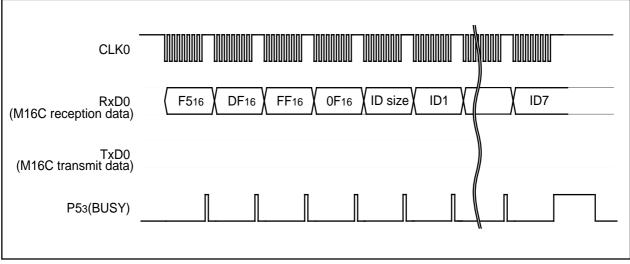

Figure 1.116. Timing for the ID check

### ID Code

When the flash memory is not blank, the ID code sent from the peripheral units and the ID code written in the flash memory are compared to see if they match. If the codes do not match, the command sent from the peripheral units is not accepted. An ID code contains 8 bits of data. Area is, from the 1st byte, addresses 0FFFDF16, 0FFFE316, 0FFFEB16, 0FFFEF16, 0FFFF316, 0FFFF716 and 0FFFFB16. Write a program into the flash memory, which already has the ID code set for these addresses.

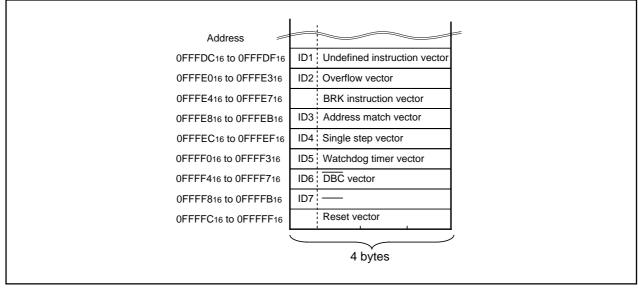

Figure 1.117. ID code storage addresses

# Status Register (SRD)

The status register indicates operating status of the flash memory and status such as whether an erase operation or a program ended successfully or in error. It can be read by writing the read status register command (7016). Also, the status register is cleared by writing the clear status register command (5016). Table 1.80 gives the definition of each status register bit. After clearing the reset, the status register outputs "8016".

	<b>2</b>	Definition			
SRD0 bits	Status name	"1"	"0"		
SR7 (bit7)	Status bit	Ready	Busy		
SR6 (bit6)	Reserved	-	-		
SR5 (bit5)	Erase bit	Terminated in error	Terminated normally		
SR4 (bit4)	Program bit	Terminated in error	Terminated normally		
SR3 (bit3)	Reserved	-	-		
SR2 (bit2)	Reserved	-	-		
SR1 (bit1)	Reserved	-	-		
SR0 (bit0)	SR0 (bit0) Reserved		-		

# Table 1.80. Status register (SRD)

# Status bit (SR7)

The status bit indicates the operating status of the flash memory. When power is turned on, "1" (ready) is set for it. The bit is set to "0" (busy) during an auto write or auto erase operation, but it is set back to "1" when the operation ends.

# Erase Status (SR5)

The erase status reports the operating status of the auto erase operation. If an erase error occurs, it is set to "1". When the erase status is cleared, it is set to "0".

# Program Status (SR4)

The program status reports the operating status of the auto write operation. If a write error occurs, it is set to "1". When the program status is cleared, it is set to "0".

# Status Register 1 (SRD1)

Status register 1 indicates the status of serial communications, results from ID checks and results from check sum comparisons. It can be read after the SRD by writing the read status register command (7016). Also, status register 1 is cleared by writing the clear status register command (5016).

Table 1.81 gives the definition of each status register 1 bit. "0016" is output when power is turned ON and the flag status is maintained even after the reset.

SRD1 bits		Def	inition	
SRUTDIIS	Status name	"1"	"0"	
SR15 (bit7)	Boot update completed bit	Update completed	Not update	
SR14 (bit6)	Reserved	-	-	
SR13 (bit5)	Reserved	-	-	
SR12 (bit4)	Checksum match bit	Match	Mismatch	
SR11 (bit3)	ID check completed bits	00 Not verified		
SP10 (hit2)		01 Verification mismatch		
SR10 (bit2)		10 Reserved		
		11 Verif	ied	
SR9 (bit1)	SR9 (bit1) Data receive time out		Normal operation	
SR8 (bit0)	Reserved	-	-	

#### Table 1.81. Status register 1 (SRD1)

### Boot Update Completed Bit (SR15)

This flag indicates whether the control program was downloaded to the RAM or not, using the download function.

### Check Sum Consistency Bit (SR12)

This flag indicates whether the check sum matches or not when a program, is downloaded for execution using the download function.

### ID Check Completed Bits (SR11 and SR10)

These flags indicate the result of ID checks. Some commands cannot be accepted without an ID check.

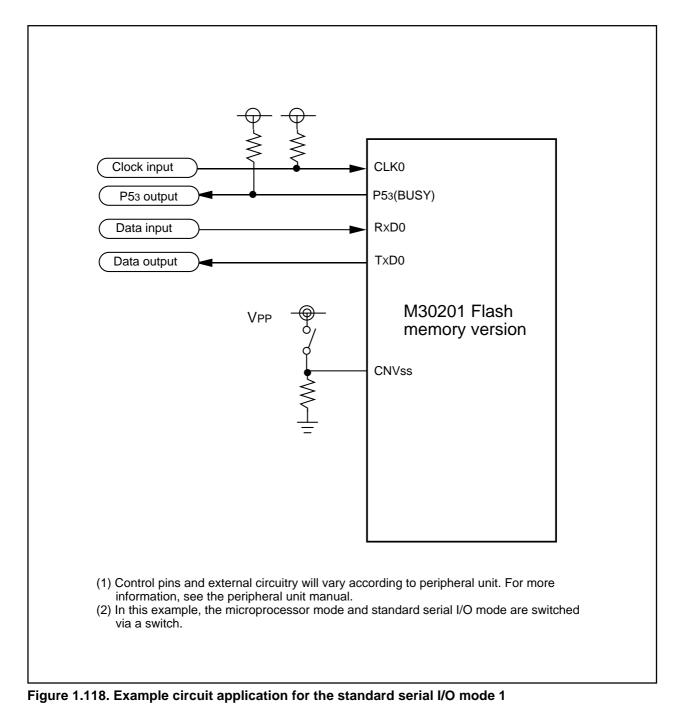

### Data Reception Time Out (SR9)

This flag indicates when a time out error is generated during data reception. If this flag is attached during data reception, the received data is discarded and the microcomputer returns to the command wait state.

# Example Circuit Application for The Standard Serial I/O Mode 1

The below figure shows a circuit application for the standard serial I/O mode 1. Control pins will vary according to programmer, therefore see the peripheral unit manual for more information.

# Overview of standard serial I/O mode 2 (clock asynchronized)

In standard serial I/O mode 2, software commands, addresses and data are input and output between the MCU and peripheral units (serial programer, etc.) using 2-wire clock-asynchronized serial I/O (UART0). Standard serial I/O mode 2 is engaged by releasing the reset with the P53 (BUSY) pin "L" level.

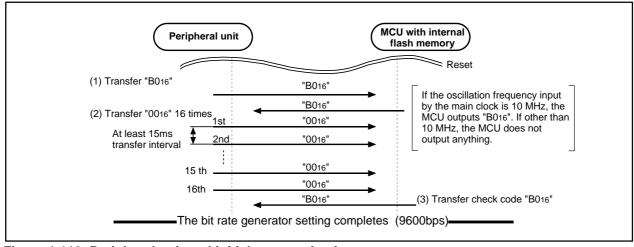

The TxDo pin is for CMOS output. Data transfer is in 8-bit units with LSB first, 1 stop bit and parity OFF. After the reset is released, connections can be established at 9,600 bps when initial communications (Figure 1.119) are made with a peripheral unit. However, this requires a main clock with a minimum 2 MHz input oscillation frequency. Baud rate can also be changed from 9,600 bps to 19,200, 38,400 or 57,600 bps by executing software commands. However, communication errors may occur because of the oscillation frequency of the main clock. If errors occur, change the main clock's oscillation frequency and the baud rate. After executing commands from a peripheral unit that requires time to erase and write data, as with erase and program commands, allow a sufficient time interval or execute the read status command and check how processing ended, before executing the next command.

Data and status registers in memory can be read after transmitting software commands. Status, such as the operating state of the flash memory or whether a program or erase operation ended successfully or not, can be checked by reading the status register. Here following are explained initial communications with peripheral units, how frequency is identified and software commands.

# Initial communications with peripheral units

After the reset is released, the bit rate generator is adjusted to 9,600 bps to match the oscillation frequency of the main clock, by sending the code as prescribed by the protocol for initial communications with peripheral units (Figure 1.119).

- (1) Transmit "B016" from a peripheral unit. If the oscillation frequency input by the main clock is 10 MHz, the MCU with internal flash memory outputs the "B016" check code. If the oscillation frequency is anything other than 10 MHz, the MCU does not output anything.
- (2) Transmit "0016" from a peripheral unit 16 times. (The MCU with internal flash memory sets the bit rate generator so that "0016" can be successfully received.)
- (3) The MCU with internal flash memory outputs the "B016" check code and initial communications end successfully \*<sup>1</sup>. Initial communications must be transmitted at a speed of 9,600 bps and a transfer interval of a minimum 15 ms. Also, the baud rate at the end of initial communications is 9,600 bps.
- \*1. If the peripheral unit cannot receive "B016" successfully, change the oscillation frequency of the main clock.

# How frequency is identified

When "0016" data is received 16 times from a peripheral unit at a baud rate of 9,600 bps, the value of the bit rate generator is set to match the operating frequency (2 - 10 MHz). The highest speed is taken from the first 8 transmissions and the lowest from the last 8. These values are then used to calculate the bit rate generator value for a baud rate of 9,600 bps.

Baud rate cannot be attained with some operating frequencies. Table 1.82 gives the operation frequency and the baud rate that can be attained for.

Operation frequency (MHz)	Baud rate 9,600bps	Baud rate 19,200bps	Baud rate 38,400bps	Baud rate 57,600bps
10MHz	$\checkmark$		_	$\checkmark$
8MHz			_	$\checkmark$
7.3728MHz			$\checkmark$	$\checkmark$
6MHz			$\checkmark$	_
5MHz			_	_
4.5MHz			_	$\checkmark$
4.194304MHz			$\checkmark$	_
4MHz			_	_
3.58MHz	$\checkmark$	$\checkmark$	$\checkmark$	$\checkmark$
3MHz	$\checkmark$	$\checkmark$	$\checkmark$	_
2MHz		_	_	_

-: Communications not possible

# Software Commands

Table 1.83 lists software commands. In the standard serial I/O mode 2, erase operations, programs and reading are controlled by transferring software commands via the RxD0 pin. Standard serial I/O mode 2 adds four transmission speed commands - 9,600, 19,200, 38,400 and 57,600 bps - to the software commands of standard serial I/O mode 1. Software commands are explained here below.

	Control command	1st byte	2nd byte	3rd byte	4th byte	5th byte	6th byte		When ID is
		transfer	Address	Address	Data	Data	Data	Data	not verified Not
1	Page read	FF <sub>16</sub>	(middle)	(high)	output	output	output	output to 259th byte	acceptable
2	Page program	41 <sub>16</sub>	Address (middle)	Address (high)	Data input	Data input	Data input	Data input to 259th byte	Not acceptable
3	Erase all unlocked blocks	A7 <sub>16</sub>	D016						Not acceptable
4	Read status register	70 <sub>16</sub>	SRD output	SRD1 output					Acceptable
5	Clear status register	5016							Not acceptable
6	Read lock bit status	71 <sub>16</sub>	Address (middle)	Address (high)	Lock bit data output				Not acceptable
7	Code processing function	F5 <sub>16</sub>	Address (low)	Address (middle)	Address (high)	ID size	ID1	To ID7	Acceptable
8	Download function	FA <sub>16</sub>	Size (low)	Size (high)	Check- sum	Data input	To required number of times		Not acceptable
9	Version data output function	FB <sub>16</sub>	Version data output	Version data output	Version data output	Version data output	Version data output	Version data output to 9th byte	Acceptable
10	Boot ROM area output function	FC <sub>16</sub>	Address (middle)	Address (high)	Data output	Data output	Data output	Data output to 259th byte	Not acceptable
11	Baud rate 9600	B0 <sub>16</sub>	B0 <sub>16</sub>						Acceptable
12	Baud rate 19200	B1 <sub>16</sub>	B1 <sub>16</sub>						Acceptable
13	Baud rate 38400	B2 <sub>16</sub>	B2 <sub>16</sub>						Acceptable
14	Baud rate 57600	B3 <sub>16</sub>	B3 <sub>16</sub>						Acceptable

Table 1.83. Software commands	(Standard serial I/O mode 2)
-------------------------------	------------------------------

Note 1: Shading indicates transfer from flash memory microcomputer to peripheral unit. All other data is transferred from the peripheral unit to the flash memory microcomputer.

Note 2: SRD refers to status register data. SRD1 refers to status register 1 data.

Note 3: All commands can be accepted when the flash memory is totally blank.

## Page Read Command

This command reads the specified page (256 bytes) in the flash memory sequentially one byte at a time. Execute the page read command as explained here following.

- (1) Transfer the "FF16" command code with the 1st byte.
- (2) Transfer addresses A8 to A15 and A16 to A23 with the 2nd and 3rd bytes respectively.
- (3) From the 4th byte onward, data (D0–D7) for the page (256 bytes) specified with addresses A8 to A23 will be output sequentially from the smallest address first in sync with the fall of the clock.

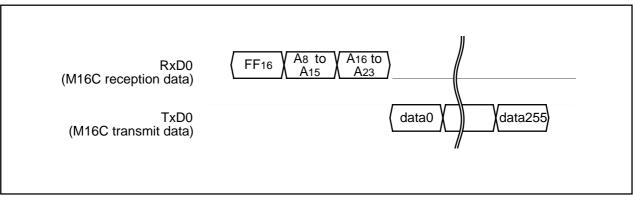

Figure 1.120. Timing for page read

## **Read Status Register Command**

This command reads status information. When the "7016" command code is sent with the 1st byte, the contents of the status register (SRD) specified with the 2nd byte and the contents of status register 1 (SRD1) specified with the 3rd byte are read.

RxD0 (M16C reception data)	7016
TxD0 (M16C transmit data)	SRD SRD1 output output

Figure 1.121. Timing for reading the status register

# **Clear Status Register Command**

This command clears the bits (SR3–SR4) which are set when the status register operation ends in error. When the "5016" command code is sent with the 1st byte, the aforementioned bits are cleared. When the clear status register operation ends, the RTS1 (BUSY) signal changes from the "H" to the "L" level.

Figure 1.122. Timing for clearing the status register

## Page Program Command

This command writes the specified page (256 bytes) in the flash memory sequentially one byte at a time. Execute the page program command as explained here following.

- (1) Transfer the "4116" command code with the 1st byte.
- (2) Transfer addresses A8 to A15 and A16 to A23 with the 2nd and 3rd bytes respectively.
- (3) From the 4th byte onward, as write data (D0–D7) for the page (256 bytes) specified with addresses A8 to A23 is input sequentially from the smallest address first, that page is automatically written.

When reception setup for the next 256 bytes ends, the RTS1 (BUSY) signal changes from the "H" to the "L" level. The result of the page program can be known by reading the status register. For more information, see the section on the status register.

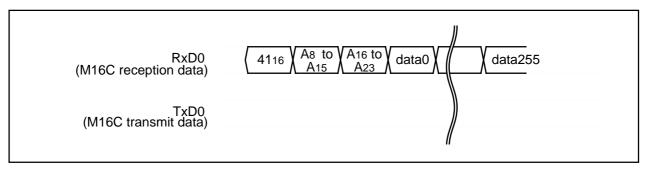

Figure 1.123. Timing for the page program

### Erase All Unlocked Blocks Command

This command erases the content of all blocks. Execute the erase all unlocked blocks command as explained here following.

(1) Transfer the "A716" command code with the 1st byte.

(2) Transfer the verify command code "D016" with the 2nd byte. With the verify command code, the erase operation will start and continue for all blocks in the flash memory.

When block erasing ends, the RTS1 (BUSY) signal changes from the "H" to the "L" level. The result of the erase operation can be known by reading the status register.

Figure 1.124. Timing for erasing all unlocked blocks

## Read Lock Bit Status Command

This command reads the lock bit status of the specified block. Execute the read lock bit status command as explained here following.

- (1) Transfer the "7116" command code with the 1st byte.
- (2) Transfer addresses A8 to A15 and A16 to A23 with the 2nd and 3rd bytes respectively.
- (3) The lock bit data of the specified block is output with the 4th byte. Write the highest address of the specified block for addresses A8 to A23.

The M30201 (flash memory version) does not have the lock bit, so the read value is always "1" (block unlock).

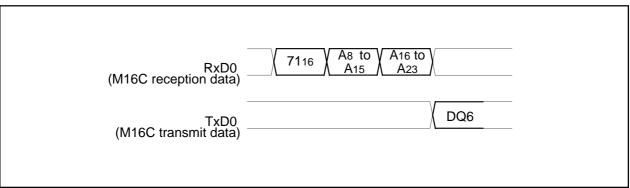

Figure 1.125. Timing for reading lock bit status

# **Download Command**

This command downloads a program to the RAM for execution. Execute the download command as explained here following.

- (1) Transfer the "FA16" command code with the 1st byte.
- (2) Transfer the program size with the 2nd and 3rd bytes.
- (3) Transfer the check sum with the 4th byte. The check sum is added to all data sent with the 5th byte onward.
- (4) The program to execute is sent with the 5th byte onward.

When all data has been transmitted, if the check sum matches, the downloaded program is executed. The size of the program will vary according to the internal RAM.

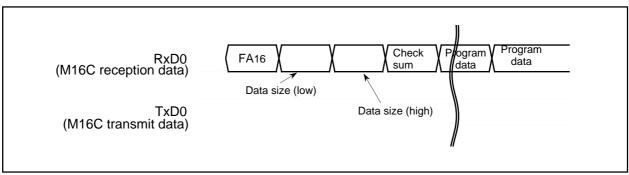

Figure 1.126. Timing for download

#### Version Information Output Command

This command outputs the version information of the control program stored in the boot area. Execute the version information output command as explained here following.

- (1) Transfer the "FB16" command code with the 1st byte.
- (2) The version information will be output from the 2nd byte onward. This data is composed of 8 ASCII code characters.

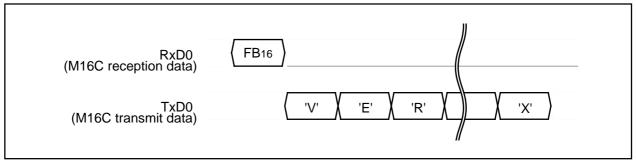

Figure 1.127. Timing for version information output

### **Boot ROM Area Output Command**

This command outputs the control program stored in the boot ROM area in one page blocks (256 bytes). Execute the boot ROM area output command as explained here following.

- (1) Transfer the "FC16" command code with the 1st byte.
- (2) Transfer addresses A8 to A15 and A16 to A23 with the 2nd and 3rd bytes respectively.
- (3) From the 4th byte onward, data (D0–D7) for the page (256 bytes) specified with addresses A8 to A23 will be output sequentially from the smallest address first.

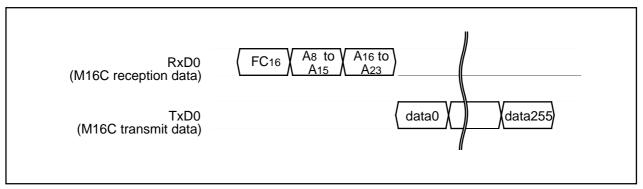

Figure 1.128. Timing for boot ROM area output

## **ID Check**

This command checks the ID code. Execute the boot ID check command as explained here following.

- (1) Transfer the "F516" command code with the 1st byte.
- (2) Transfer addresses A0 to A7, A8 to A15 and A16 to A23 of the 1st byte of the ID code with the 2nd, 3rd and 4th bytes respectively.
- (3) Transfer the number of data sets of the ID code with the 5th byte.
- (4) The ID code is sent with the 6th byte onward, starting with the 1st byte of the code.

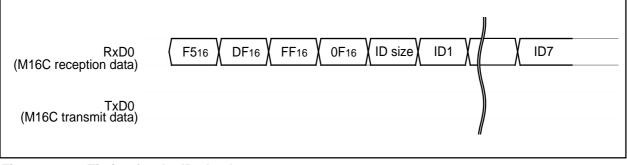

Figure 1.129. Timing for the ID check

## ID Code

When the flash memory is not blank, the ID code sent from the peripheral units and the ID code written in the flash memory are compared to see if they match. If the codes do not match, the command sent from the peripheral units is not accepted. An ID code contains 8 bits of data. Area is, from the 1st byte, addresses 0FFFDF16, 0FFFE316, 0FFFEB16, 0FFFEF16, 0FFFF316, 0FFFF716 and 0FFFFB16. Write a program into the flash memory, which already has the ID code set for these addresses.

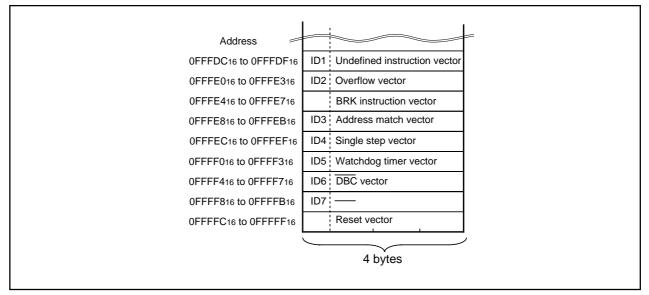

Figure 1.130. ID code storage addresses

#### Baud Rate 9600

This command changes baud rate to 9,600 bps. Execute it as follows.

- (1) Transfer the "B016" command code with the 1st byte.
- (2) After the "B016" check code is output with the 2nd byte, change the baud rate to 9,600 bps.

RxD0 (M16C reception data)	B016
TxD0 (M16C transmit data)	(B016)

Figure 1.131. Timing of baud rate 9600

#### Baud Rate 19200

This command changes baud rate to 19,200 bps. Execute it as follows.

- (1) Transfer the "B116" command code with the 1st byte.
- (2) After the "B116" check code is output with the 2nd byte, change the baud rate to 19,200 bps.

RxD0 (M16C reception data)	(B116)
TxD0 (M16C transmit data)	B116

Figure 1.132. Timing of baud rate 19200

#### Baud Rate 38400

This command changes baud rate to 38,400 bps. Execute it as follows.

- (1) Transfer the "B216" command code with the 1st byte.
- (2) After the "B216" check code is output with the 2nd byte, change the baud rate to 38,400 bps.

RxD0 (M16C reception data)	B216
TxD0 (M16C transmit data)	B216

#### Baud Rate 57600

This command changes baud rate to 57,600 bps. Execute it as follows.

- (1) Transfer the "B316" command code with the 1st byte.
- (2) After the "B316" check code is output with the 2nd byte, change the baud rate to 57,600 bps.

RxD0 (M16C reception data)	B316	
TxD0 (M16C transmit data)	B316

## -Keep safety first in your circuit designs!-

 Mitsubishi Electric Corporation puts the maximum effort into making semiconductor products better and more reliable, but there is always the possibility that trouble may occur with them. Trouble with semiconductors may lead to personal injury, fire or property damage. Remember to give due consideration to safety when making your circuit designs, with appropriate measures such as (i) placement of substitutive, auxiliary circuits, (ii) use of non-flammable material or (iii) prevention against any malfunction or mishap.

# Notes regarding these materials

- These materials are intended as a reference to assist our customers in the selection of the Mitsubishi semiconductor product best suited to the customer's application; they do not convey any license under any intellectual property rights, or any other rights, belonging to Mitsubishi Electric Corporation or a third party.
- Mitsubishi Electric Corporation assumes no responsibility for any damage, or infringement of any third-party's rights, originating in the use of any product data, diagrams, charts, programs, algorithms, or circuit application examples contained in these materials.
- All information contained in these materials, including product data, diagrams, charts, programs and algorithms represents information on products at the time of publication of these materials, and are subject to change by Mitsubishi Electric Corporation without notice due to product improvements or other reasons. It is therefore recommended that customers contact Mitsubishi Electric Corporation or an authorized Mitsubishi Semiconductor product distributor for the latest product information before purchasing a product listed herein.

The information described here may contain technical inaccuracies or typographical errors. Mitsubishi Electric Corporation assumes no responsibility for any damage, liability, or other loss rising from these inaccuracies or errors.

Please also pay attention to information published by Mitsubishi Electric Corporation by various means, including the Mitsubishi Semiconductor home page (http://www.mitsubishichips.com).

- When using any or all of the information contained in these materials, including product data, diagrams, charts, programs, and algorithms, please be sure to evaluate all information as a total system before making a final decision on the applicability of the information and products. Mitsubishi Electric Corporation assumes no responsibility for any damage, liability or other loss resulting from the information contained herein.
- Mitsubishi Electric Corporation semiconductors are not designed or manufactured for use in a device or system that is used under circumstances in which human life is potentially at stake. Please contact Mitsubishi Electric Corporation or an authorized Mitsubishi Semiconductor product distributor when considering the use of a product contained herein for any specific purposes, such as apparatus or systems for transportation, vehicular, medical, aerospace, nuclear, or undersea repeater use.
- The prior written approval of Mitsubishi Electric Corporation is necessary to reprint or reproduce in whole or in part these materials.
- If these products or technologies are subject to the Japanese export control restrictions, they must be exported under a license from the Japanese government and cannot be imported into a country other than the approved destination. Any diversion or reexport contrary to the export control laws and regulations of Japan and/or the country of destination is prohibited.
- Please contact Mitsubishi Electric Corporation or an authorized Mitsubishi Semicon ductor product distributor for further details on these materials or the products con tained therein.
