- POS/NEG SYNC INPUT
- SYNC POLARITY DETECTION
- 2 PLLs CONCEPT
- 2 COMPLEMENTARY OUTPUTS
- DC ADJUSTABLE FREQUENCY
- DC ADJUSTABLE DUTY CYCLE
- X-RAY PROT INPUT
- BACK PORCH CLAMPING PULSE GENERATOR
- H-DRIVE INHIBITION WHEN $V_S < V_{S \text{ START}}$

DESCRIPTION

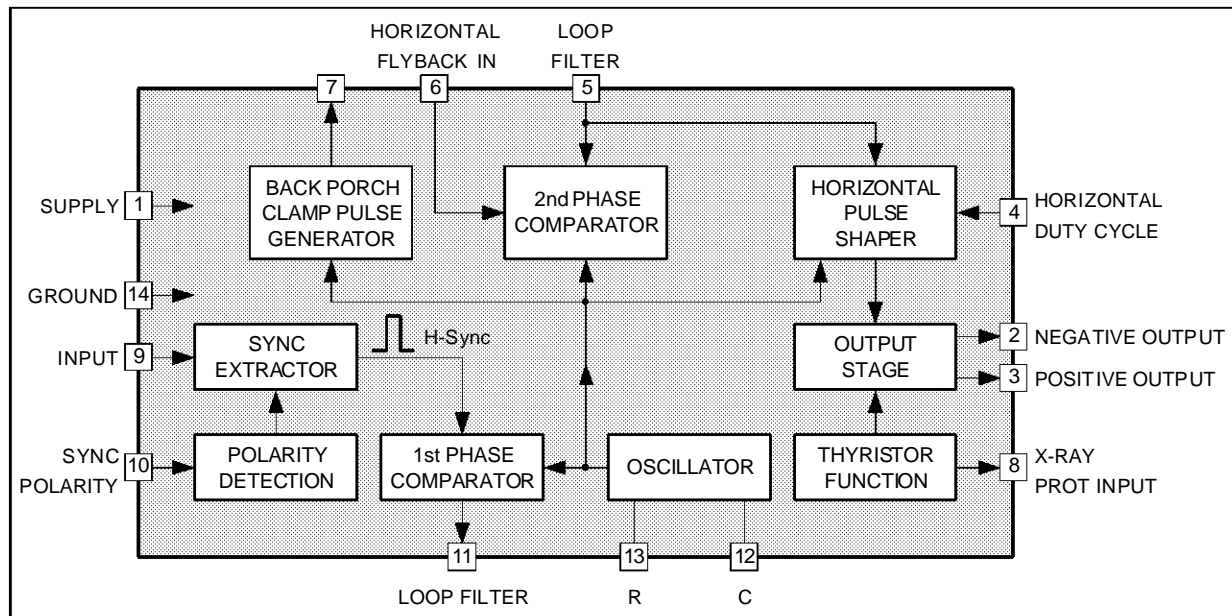

The TDA9108 is a horizontal deflection processor specially designed for monitor applications. The H-drive output duty cycle, the horizontal frequency and the horizontal position are DC adjustable ; it accepts both POS/NEG polarity on sync input and delivers polarity information on a dedicated pin. All these features make the device a good choice for multifrequency application. In addition to this, X-ray protection, 2 complementary H-drive output , and a back porch clamping pulse generator are also included. It is a monolithic integrated circuit encapsulated in a 14 lead dual line plastic package.

TYPICAL APPLICATION

9108-06.EPS

APPLICATION INFORMATION

Sync Extractor and Polarity Detection

This circuit is able to handle both positive or negative TTL input signal on Pin 9. The voltage on Pin 10 drives an internal inverter providing a constant sync polarity to the 1st phase comparator.

When using a RC network between Pin 9 and 10 (see Typical Application), the IC will adapt itself automatically to positive or negative sync. On an other hand, and in order to simplified the application, the Pin 10 can be connected to ground or supply (through a resistor), in this case the IC will work only with one sync polarity.

1st PLL

It is composed by a phase comparator, the oscillator and an external loop filter (see Figure 2)

- The phase comparator receives the H-sync signal (with positive polarity) and a signal coming from the internal current controlled oscillator. The loop is closed through an external resistor between Pin 11 and 13.
- The oscillator generates a sawtooth waveform on Pin 12 by charging and discharging the external capacitor. The capacitor is discharging by the current flowing Pin 13 and charged by two times this latter (see Figure 3).

The sawtooth is used internally to generate all the required timings.

It is possible to DC control the frequency by adding or subtracting a DC current on Pin 13 (see Figure 2).

Figure 2

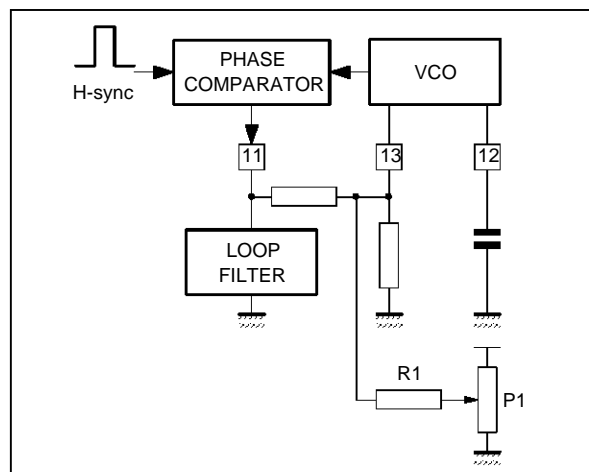

Figure 3

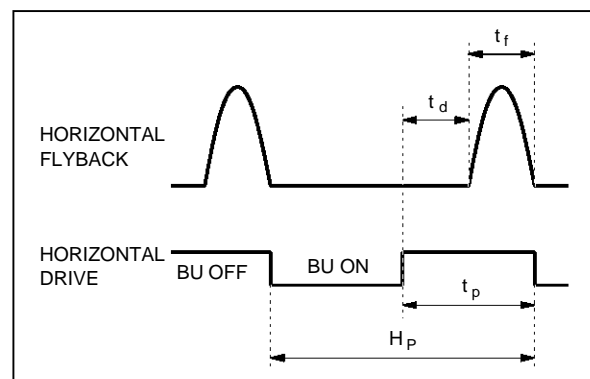

2nd Phase Locked Loop

To compensate the delay introduced by the horizontal final stage, the flyback pulse (Pin 6) and the oscillator waveform (Pin 12) are compared in the 2nd phase comparator. The result of the comparison is a control current which, after it has been filtered by the external capacitor on Pin 5, is sent to a phase shifter which adequately regulates the horizontal output pulses phase.

The maximum phase shift allowed is $t_d = t_p - t_f$ where t_f is the flyback duration (see Figure 4).

If $t_d > t_p - t_f$, then the horizontal output transistor will be turned on during flyback destroying it.

Figure 4

X-Ray Protection Input (Pin 8)

When the voltage on this pin becomes higher than 2.9V (typ.), the horizontal outputs are inhibited and will remain in this condition until a reset is made on supply voltage (power-off/power-on).

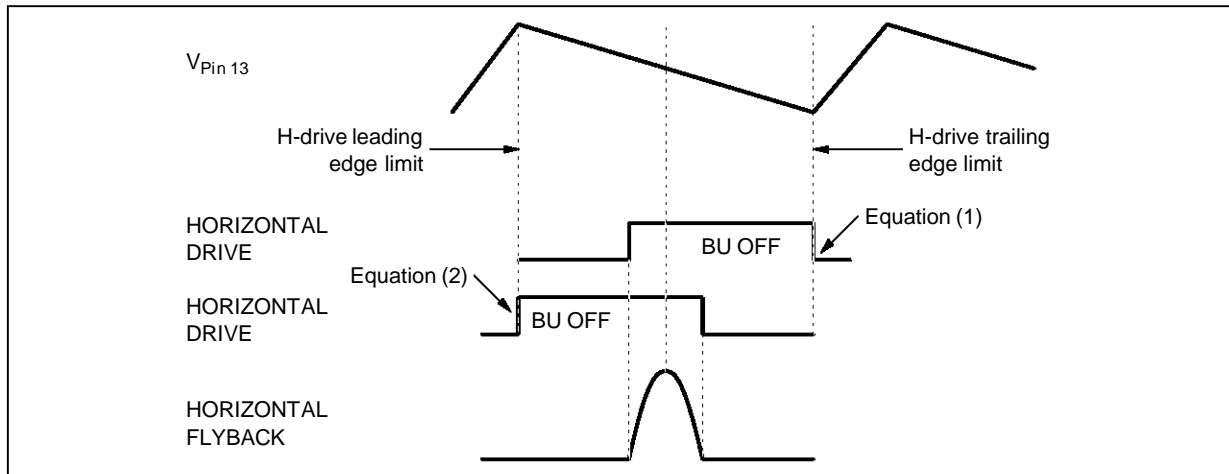

H-Duty Cycle (see Figure 5)

The output duty cycle is variable between 0 and 50% by varying the voltage on Pin 4.

In order to maintain ± 5% horizontal phase adjustment possibilities the following equation must be respected.

- (1) $H_{\text{period}} \left[\frac{t_p}{100} - 0.25 \right] - \frac{t_{\text{fly}}}{2} \leq t_d \Rightarrow$ If not, t_p will decrease because of H-drive trailing edge wrong position (phase shifter saturation)
- (2) $t_d \leq 0.36 H_p - \frac{t_{\text{fly}}}{2} - 2\mu\text{s} \Rightarrow$ If not, t_p will decrease because of H-drive leading edge wrong position (phase shifter saturation)
