## DESCRIPTION

The QS5919 Clock Driver uses an internal phase locked loop (PLL) to lock low skew outputs to one of two reference clock inputs. Eight outputs are available: 2xQ, Q<sub>0</sub>-Q<sub>4</sub>,  $\bar{Q}$ <sub>5</sub>, Q/2. Careful layout and design ensure < 500ps skew between the Q<sub>0</sub>-Q<sub>4</sub>, and Q/2 outputs. The QS5919 includes an internal RC filter which provides excellent jitter characteristics and eliminates the need for external components. Various combinations of feedback and a divide-by-2 in the VCO path allow applications to be customized for linear VCO operation over a wide range of input SYNC frequencies. The PLL can also be disabled by the PLL\_EN signal to allow low frequency or DC testing. The LOCK output asserts to indicate when phase lock has been achieved. The QS5919 is designed for use in high-performance workstations, multi-board computers, networking hardware, and mainframe systems. Several can be used in parallel or scattered throughout a system for guaranteed low skew, system-wide clock distribution networks.

1. Operation in the specified SYNC frequency range guarantees that the VCO will operate in its optimal range of 20MHz to F<sub>MAX\_2xQ</sub>. Operation with Sync inputs outside specified frequency ranges may result in out-of-lock outputs. FREQ\_SEL only affects VCO frequency and does not affect output frequencies.
2. The lock output pin (LOCK) may not indicate reliably for VCO frequencies below 30MHz.

## PLL OPERATION

The Phase Locked Loop (PLL) circuit included in the QS5919 provides for replication of incoming SYNC clock signals. Any manipulation of that signal, such as frequency multiplying or inversion is performed by digital logic following the PLL (see the block diagram). The key advantage of the

PLL circuit is to provide an effective zero propagation delay between the output and input signals. In fact, adding delay circuits in the feedback path, 'propagation delay' can even be negative! A simplified schematic of the QS5919 PLL circuit is shown below.

## SIMPLIFIED DIAGRAM OF QS5919 FEEDBACK

The phase difference between the output and the input frequencies feeds the VCO which drives the outputs. Whichever output is fed back, it will stabilize at the same frequency as the input. Hence, this is a true negative feedback closed loop system. In most applications, the output will optimally have zero phase shift with respect to the input. In fact, the internal loop filter on the QS5919 typically provides within 150ps of phase shift between input and output.

If the user wishes to vary the phase difference (typically to compensate for backplane delays), this is most easily accomplished by adding delay circuits to the feedback path. The respective output used for feedback will be advanced by the amount of delay in the feedback path. All other outputs will retain their proper relationships to that output.
