

FEATURES

Ideal for current shunt applications

High common-mode voltage range

–2 V to +65 V operating

–5 V to +68 V survival

Gain = 20

Wide operating temperature range

Die: –40°C to +150°C

8-lead SOIC: –40°C to +125°C

Adjustable offset

Available in SOIC and die form

EXCELLENT AC AND DC PERFORMANCE

15 $\mu\text{V}/^\circ\text{C}$ offset drift

30 ppm/ $^\circ\text{C}$ gain drift

80 dB CMRR dc to 20 kHz

APPLICATIONS

High-side current sensing in:

Motor controls

Transmission controls

Diesel injection controls

Engine management

Suspension controls

Vehicle dynamic controls

DC-to-DC converters

GENERAL DESCRIPTION

The AD8206 is a single-supply difference amplifier for amplifying small differential voltages in the presence of large common-mode voltages. The operating input common-mode voltage range extends from –2 V to +65 V. The typical single-supply voltage is 5 V.

The AD8206 is offered in die and packaged form. The operating temperature range for the die is 25°C higher (up to 150°C) than the packaged part to enable the user to apply the AD8206 in high temperature applications.

FUNCTIONAL BLOCK DIAGRAM

Figure 1.

Excellent dc performance over temperature keeps errors in the measurement loop to a minimum. Offset drift is typically less than 15 $\mu\text{V}/^\circ\text{C}$, and gain drift is typically below 30 ppm/ $^\circ\text{C}$.

The output offset can be adjusted from 0.05 V to 4.8 V with a 5 V supply by using the V_{REF1} and V_{REF2} pins. With V_{REF1} attached to the V+ pin, and V_{REF2} attached to the GND pin, the output is set at half scale. Attaching both pins to GND causes the output to be unipolar, starting near ground. Attaching both pins to V+ causes the output to be unipolar starting near V+. Other offsets can be obtained by applying an external voltage to the V_{REF1} and V_{REF2} pins.

¹ Input voltage range = ±125 mV with half-scale offset.

² Source imbalance < 2 Ω.

³ The offset adjustment is ratiometric to the power supply when V_{REF1} and V_{REF2} are used as a divider between the supplies.

ABSOLUTE MAXIMUM RATINGS

Table 2.

Parameter	Rating
Supply Voltage	12.5 V
Continuous Input Voltage	−5 V to +68 V
Reverse Supply Voltage	0.3 V
Operating Temperature Range	−40°C to +125°C
Storage Temperature	−65 to +150°C
Output Short-Circuit Duration	Indefinite

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

THEORY OF OPERATION

The AD8206 is a single-supply difference amplifier that uses a unique architecture to accurately amplify small differential current shunt voltages in the presence of rapidly changing common-mode voltages. It is offered in both packaged and die form.

In typical applications, the AD8206 is used to measure current by amplifying the voltage across a current shunt placed across the inputs.

The gain of the AD8206 is 20 V/V, with an accuracy of 1.2%. This accuracy is guaranteed over the operating temperature range of -40°C to $+125^{\circ}\text{C}$. The die temperature range is -40°C to $+150^{\circ}\text{C}$ with a guaranteed gain accuracy of 1.3%.

The input offset is less than 2 mV referred to the input at 25°C , and 4.5 mV maximum referred to the input over the full operating temperature range for the packaged part. The die input offset is less than 6 mV referred to the input over the die operating temperature range.

The AD8206 operates with a single supply from 4.5 V to 10 V (absolute maximum = 12.5 V). The supply current is less than 2 mA.

High accuracy trimming of the internal resistors allows the AD8206 to have a common-mode rejection ratio better than 78 dB from dc to 20 kHz. The common-mode rejection ratio over the operating temperature is 76 dB for both the die and packaged part.

The output offset can be adjusted from 0.05 V to 4.8 V ($V_{+} = 5\text{ V}$) for unipolar and bipolar operation.

The AD8206 consists of two amplifiers (A1 and A2), a resistor network, small voltage reference, and a bias circuit (not shown), see Figure 13.

The set of input attenuators preceding A1 consist of R_A , R_B , and R_C , which reduce the common-mode voltage to match the input voltage range of A1. The two attenuators form a balanced bridge network. When the bridge is balanced, the differential voltage created by a common-mode voltage is 0 V at the inputs of A1. The input attenuation ratio is 1/16.7. The combined series resistance of R_A , R_B , and R_C is approximately $200\text{ k}\Omega \pm 20\%$.

By attenuating the voltages at Pin 1 and Pin 8, the A1 amplifier inputs are held within the power supply range, even if Pin 1 and Pin 8 exceed the supply or fall below common (ground). A reference voltage of 250 mV biases the attenuator above ground. This allows the amplifier to operate in the presence of negative common-mode voltages.

The input network also attenuates normal (differential) mode voltages. A1 amplifies the attenuated signal by 26. The input and output of this amplifier are differential to maximize the ac common-mode rejection.

A2 converts the differential voltage from A1 into a single-ended signal and provides further amplification. The gain of this second stage is 12.86.

The reference inputs, V_{REF1} and V_{REF2} , are tied through resistors to the positive input of A2, which allows the output offset to be adjusted anywhere in the output operating range. The gain is 1 V/V from the reference pins to the output when the reference pins are used in parallel. The gain is 0.5 V/V when they are used to divide the supply.

The ratios of Resistors R_A , R_B , R_C , R_D , and R_F are trimmed to a high level of precision to allow the common-mode rejection ratio to exceed 80 dB. This is accomplished by laser trimming the resistor ratio matching to better than 0.01%.

The total gain of 50 is made up of the input attenuation of 1/16.7 multiplied by the first stage gain of 26 and the second stage gain of 12.86.

The output stage is Class A with a PNP pull-up transistor and a 300 μA current sink pull-down.

Figure 13. Simplified Schematic

OUTPUT OFFSET ADJUSTMENT

The output of the AD8206 can be adjusted for unidirectional or bidirectional operation.

UNIDIRECTIONAL OPERATION

Unidirectional operation allows the AD8206 to measure currents through a resistive shunt in one direction. The basic modes for unidirectional operation are ground referenced output mode and V_+ referenced output mode.

In the case of unidirectional operation, the output could be set at the negative rail (near ground) or at the positive rail (near V_+) when the differential input is 0 V. The output moves to the opposite rail when a correct polarity differential input voltage is applied. In this case, full scale is approximately 250 mV. The required polarity of the differential input depends on the output voltage setting. If the output is set at the positive rail, the input polarity needs to be negative to move the output down. If the output is set at ground, the polarity is positive to move the output up.

GROUND REFERENCED OUTPUT

When using the AD8206 in this mode, both reference inputs are tied to ground, which causes the output to sit at the negative rail when there are zero differential volts at the input (see Figure 14).

Figure 14. Ground Referenced Output

Table 4. $V_+ = 5\text{ V}$

V_{IN} (Referred to $-IN$)	V_O
0 V	0.05 V
250 mV	4.8 V

V_+ REFERENCED OUTPUT

This mode is set when both reference pins are tied to the positive supply. It is typically used when the diagnostic scheme requires detection of the amplifier and the wiring before power is applied to the load (see Figure 15).

Figure 15. V_+ Referenced Output

Table 5. $V_+ = 5\text{ V}$

V_{IN} (Referred to $-IN$)	V_O
0 V	4.8 V
250 mV	0.05 V

BIDIRECTIONAL OPERATION

Bidirectional operation allows the AD8206 to measure currents through a resistive shunt in two directions.

In this case, the output is set anywhere within the output range. Typically, it is set at half-scale for equal range in both directions. In some cases, however, it is set at a voltage other than half-scale when the bidirectional current is nonsymmetrical.

Table 6. $V_+ = 5\text{ V}$, $V_O = 2.5$ with $V_{IN} = 0\text{ V}$

V_{IN} (Referred to $-IN$)	V_O
+100 mV	4.5 V
-100 mV	0.5 V

Adjusting the output is accomplished by applying voltage(s) to the reference inputs.

V_{REF1} and V_{REF2} are tied to internal resistors that connect to an internal offset node. There is no operational difference between the pins.

EXTERNAL REFERENCE OUTPUT

Tying both pins together and to a reference produces an output at the reference voltage when there is no differential input (see Figure 16). The output moves down from the reference voltage when the input is negative relative to the $-IN$ pin and up when the input is positive relative to the $-IN$ pin.

Figure 16. External Reference Output

SPLITTING THE SUPPLY

By tying one reference pin to $V+$ and the other to the ground pin, the output is set at half of the supply when there is no differential input (see Figure 17). The benefit is that no external reference is required to offset the output for bidirectional current measurement. This creates a midscale offset that is ratiometric to the supply, which means that if the supply increases or decreases, the output remains at half the supply. For example, if the supply is 5.0 V, the output is at half scale or 2.5 V. If the supply increases by 10% (to 5.5 V), the output goes to 2.75 V.

Figure 17. Split Supply

SPLITTING AN EXTERNAL REFERENCE

In this case, an external reference is divided by 2 with an accuracy of approximately 0.5% by connecting one V_{REF} pin to ground and the other V_{REF} pin to the reference (see Figure 18).

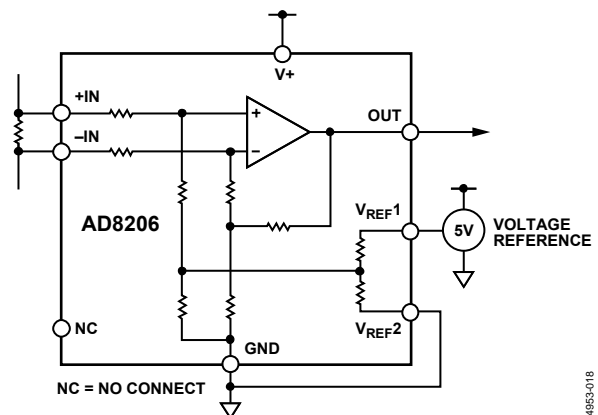

Figure 18. Split External Reference

APPLICATIONS

A typical application for the AD8206 is high-side measurement of a current through a solenoid for PWM control of the solenoid opening. Typical applications include hydraulic transmission control and diesel injection control.

Two typical circuit configurations are used for this type of application.

HIGH-SIDE CURRENT SENSE WITH A LOW-SIDE SWITCH

In this case, the PWM control switch is ground referenced. An inductive load (solenoid) is tied to a power supply. A resistive shunt is placed between the switch and the load (see Figure 19). An advantage of placing the shunt on the high side is that the entire current, including the re-circulation current, can be measured since the shunt remains in the loop when the switch is off. In addition, diagnostics can be enhanced because shorts to ground can be detected with the shunt on the high side.

In this circuit configuration, when the switch is closed, the common-mode voltage moves down to near the negative rail. When the switch is opened, the voltage reversal across the inductive load causes the common-mode voltage to be held one diode drop above the battery by the clamp diode.

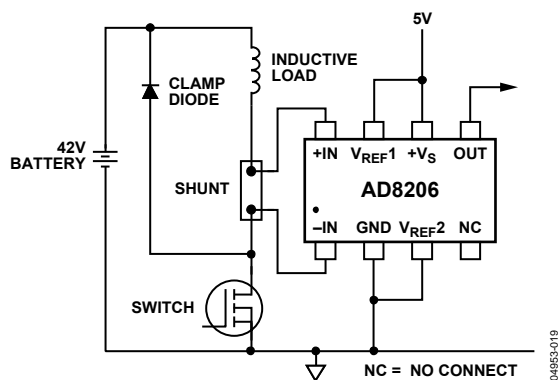

Figure 19. Low-Side Switch

HIGH-SIDE CURRENT SENSE WITH A HIGH-SIDE SWITCH

This configuration minimizes the possibility of unexpected solenoid activation and excessive corrosion (see Figure 20). In this case, both the switch and the shunt are on the high side. When the switch is off, this removes the battery from the load, which prevents damage from potential shorts to ground, while still allowing the recirculating current to be measured and providing for diagnostics. Removing the power supply from the load for the majority of the time minimizes the corrosive effects that could be caused by the differential voltage between the load and ground.

When using a high-side switch, the battery voltage is connected to the load when the switch is closed, causing the common-mode voltage to increase to the battery voltage. In this case, when the switch is opened, the voltage reversal across the inductive load causes the common-mode voltage to be held one diode drop below ground by the clamp diode.

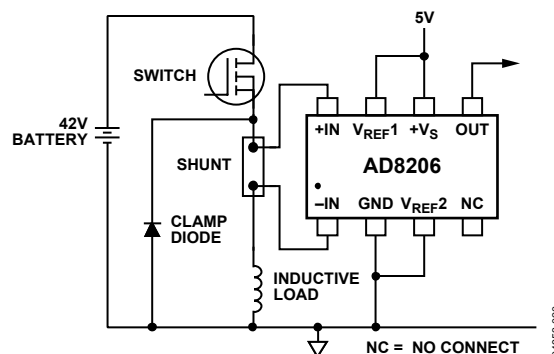

Figure 20. High-Side Switch

Another typical application for the AD8206 is as part of the control loop in H-bridge motor control. In this case, the AD8206 is placed in the middle of the H-bridge (see Figure 21) so that it can accurately measure current in both directions by using the shunt available at the motor. This is a better solution than a ground referenced op amp because ground is not typically a stable reference voltage in this type of application. This instability in the ground reference causes the measurements that could be made with a simple ground referenced op amp to be inaccurate.

The AD8206 measures current in both directions as the H-bridge switches and the motor changes direction. The output of the AD8206 is configured in an external reference bidirectional mode, see the Output Offset Adjustment section.
