

MIC2871

1.2A High-Brightness LED Flash Driver with Single-Wire Serial Interface

General Description

The MIC2871 is a high-current, high-efficiency flash LED driver. The LED driver current is generated by an integrated inductive boost converter with a 2MHz switching frequency which allows the use of very small inductor and output capacitor. These features make the MIC2871 an ideal solution for high-resolution camera phone LED flash light driver applications.

The MIC2871 operates in either flash or torch modes that can be controlled through the single-wire serial interface and/or external control pins. Default flash and torch brightness can be adjusted via an external resistor. A robust single-wire serial interface allows simple control by the host processor to support typical camera functions such as auto-focus, white balance, and image capture (flash mode).

The MIC2871 is available in a 14-pin 3mm x 2mm LDFN package with a junction temperature range of -40°C to $+125^{\circ}\text{C}$.

Datasheets and support documentation are available on Micrel's web site at: www.micrel.com.

Features

- Up to 1.2A flash LED driving current
- Highly-efficient, synchronous boost driver (up to 94%)
- $\pm 5\%$ LED current accuracy
- Control through single-wire serial interface or external control pins
- Input voltage range: 2.7V to 5.5V
- True load disconnect
- Configurable safety time-out protection
- Output overvoltage protection (OVP)
- LED short detection and protection.
- 1 μA shutdown current
- Available in 14-pin 3mm x 2mm LDFN package

Applications

- Camera phones/mobile handsets
- Cell phones/smartphones
- LED light for image capture/auto focus/white balance
- Handset video light (torch light)
- Digital cameras
- Portable applications

Typical Application

Ordering Information

Part Number	Marking Code	Temperature Range	Package ⁽¹⁾	Lead Finish
MIC2871YMK	2871	-40°C to +125°C	14-pin 3mm x 2mm LDFN	Pb-Free

Note:

1. Package is a GREEN RoHS-compliant package. Lead finish is Pb-Free. Mold compound is Halogen Free.

Pin Configuration

**14-Pin 3mm x 2mm LDFN (MK)
(Top View)**

Pin Description

Pin Number	Pin Name	Pin Function
1	AGND1	Analog Ground. LED current return path.
2	DC	Single-wire serial interface control input.
3	LED	LED Current Sink Pin. Connect the LED anode to OUT and cathode to this pin.
4	FEN1	Flash Mode Enable Pin. Toggling FEN1 from LOW to HIGH enables MIC2871 into the flash mode. FEN1 is logic-OR with FEN2. If this pin is left floating, it is pulled-down internally by a built-in 1 μ A current source when the device is enabled.
5	AGND2	Analog Ground. Reference ground of the FRSET pin.
6	VIN	Supply Input Pin. Connect a low-ESR ceramic capacitor of at least 2.2 μ F to AGND2.
7	PGND1	Power Ground. Inductor current return path.
8	OUT	Boost Converter Output Pin. This is connected to the anode of the LED. Connect a low ESR ceramic capacitor of at least 4.7 μ F to PGND1.
9, 12	NC	No Connect. Connect this pin to AGND or leave it floating.
10	SW	Inductor Connection Pin. It is connected to the internal power MOSFETs.
11	FEN2	Additional Flash Mode Enable Pin. FEN2 is logic-OR with FEN1. If this pin is left floating, it is pulled-down internally by a built-in 1 μ A current source when the device is enabled.
13	PGND2	Power Ground.
14	FRSET	Flash Mode Current-Level Programming Pin. Connect a resistor from this pin to AGND2 to set the maximum current in the flash mode. This pin may be grounded if the default flash mode current (1A) is desired. This pin cannot be left floating and the recommended resistance range is from 17k Ω to 60k Ω .
EP	ePad	Exposed Heat Sink Pad. Connect to ground for best thermal performance.

Absolute Maximum Ratings⁽²⁾

Input Voltage (V_{IN})	-0.3V to +6.0V
General I/O Voltage (V_{FEN1} , V_{FEN2})	-0.3V to V_{IN}
V_{OUT} and V_{LED} Voltage	-0.3V to +6.0V
Single-Wire I/O Voltage (V_{DC})	-0.3V to V_{IN}
V_{FRSET} Voltage	-0.3V to V_{IN}
V_{SW} Voltage	-0.3V to +6.0V
Lead Temperature (soldering, 10s)	+260°C
Junction Temperature	0°C to +150°C
Storage Temperature (T_s)	-40°C to +150°C
ESD Rating ⁽⁵⁾	2kV, HBM and 200V, MM

Operating Ratings⁽³⁾

Input Voltage (V_{IN})	2.7V to +5.5V
Enable Input Voltage (V_{FEN1} , V_{FEN2})	0V to V_{IN}
Single-Wire I/O Voltage (V_{DC})	0V to V_{IN}
Junction Temperature (T_J)	-40°C to +125°C
Power Dissipation (P_D)	Internally Limited ⁽⁴⁾
Package Thermal Resistance	
3mm x 2mm LDFN (θ_{JA}) ⁽⁴⁾	65.83°C/W
3mm x 2mm LDFN (θ_{JC}) ⁽⁴⁾	38.9°C/W

Electrical Characteristics⁽⁶⁾

$V_{IN} = 3.6V$, $L = 1\mu H$, $C_{OUT} = 4.7\mu F$, $R_{FRSET} = 20.5k\Omega$, $I_{OUT} = 100mA$, $T_A = 25^\circ C$, **bold** values indicate $-40^\circ C \leq T_J \leq +125^\circ C$, unless otherwise noted..

Symbol	Parameter	Condition	Min.	Typ.	Max.	Units
Power Supply						
V_{IN}	Supply Voltage Range		2.7		5.5	V
V_{START}	Start-Up Voltage			2.65	2.95	V
V_{UVLO}	UVLO Threshold (falling)			2.30	2.5	V
I_{STB}	Standby Current	$V_{DC} = HIGH$, boost regulator and LED current driver both OFF.		230		μA
I_{SD}	Shutdown Current	$V_{DC} = 0V$		1	2	μA
V_{OVP}	Overvoltage Protection (OVP) Threshold		5.2	5.37	5.55	V
	OVP Hysteresis			60		mV
	OVP Blanking Time			23		μs
D_{MAX}	Maximum Duty Cycle		82	86	90	%
I_{SW}	Switch Current Limit	$V_{IN} = V_{OUT} = 2.7V$	3.5	4.5	5.5	A
D_{MIN}	Minimum Duty Cycle		4	6.4	9	%
PMOS	Switch On-Resistance	$I_{SW} = 100mA$		100		m Ω
NMOS		$I_{SW} = 100mA$				
I_{SW}	Switch Leakage Current	$V_{DC} = 0V$, $V_{SW} = 5.5V$		0.01	1	μA
F_{SW}	Oscillator Frequency			2		MHz
	Oscillator Frequency Variation		-10		10	%

Notes:

- Exceeding the absolute maximum rating may damage the device.
- The device is not guaranteed to function outside its operating rating.
- The maximum allowable power dissipation of any T_A (ambient temperature) is $P_{D(max)} = (T_{J(max)} - T_A) / \theta_{JA}$. Exceeding the maximum allowable power dissipation will result in excessive die temperature, and the regulator will go into thermal shutdown.
- Devices are ESD sensitive. Handling precautions recommended. Human body model, 1.5k Ω in series with 100pF.
- Specification for packaged product only.

Electrical Characteristics⁽⁶⁾

$V_{IN} = 3.6V$, $L = 1\mu H$, $C_{OUT} = 4.7\mu F$, $R_{FRSET} = 20.5k\Omega$, $I_{OUT} = 100mA$, $T_A = 25^\circ C$, **bold** values indicate $-40^\circ C \leq T_J \leq +125^\circ C$, unless otherwise noted.

Functional Diagram

Figure 1. Simplified MIC2871 Functional Block Diagram

Functional Description

VIN

The input supply provides power to the internal MOSFETs gate drive and controls circuitry for the switch-mode regulator. The operating input voltage range is from 2.7V to 5.5V. A 2.2 μ F low-ESR ceramic input capacitor should be connected from VIN to AGND2 as close to the MIC2871 as possible to ensure a clean supply voltage for the device. The minimum voltage rating of 10V is recommended for the input capacitor.

SW

The MIC2871 has internal low-side and synchronous MOSFET switches. The switch node (SW) between the internal MOSFET switches connects directly to one end of the inductor and provides the current paths during switching cycles.

The other end of the inductor is connected to the input supply voltage. Due to the high-speed switching on this pin, the switch node should be routed away from sensitive nodes wherever possible.

AGND1

This is the ground path of the LED current sink. It should be connected to the AGND2, but not via exposed pad, on the PCB. The current loop of the analog ground should be separated from that of the power ground (PGND1 and PGND2). AGND1 and AGND2 should be connected to PGND1 and PGND2 at a single point.

AGND2

This is the ground path for the internal biasing and control circuitry. AGND2 should be connected to the PCB pad for the package exposed pad. AGND2 should be connected to the AGND1 directly without going through the exposed pad. The current loop of the analog ground should be separated from that of the power ground (PGND1 and PGND2). The AGND2 and AGND1 should be connected to PGND1 and PGND2 at a single point.

PGND1 and PGND2

The power ground pins are the ground path for the high current in the boost switch and they are internally connected together. The current loop for the power ground should be as small as possible and separate from the analog ground (AGND) loop as applicable.

OUT

Boost converter output pin which is connected to the anode of the LED. A low-ESR ceramic capacitor of 4.7 μ F or larger should be connected from OUT to PGND1 as close as possible to the MIC2871. The minimum voltage rating of 10V is recommended for the output capacitor.

LED

The current sink pin for the LED. The LED anode is connected to the OUT pin and the LED cathode is connected to this pin.

DC

The DC is a single multiplexed device enable and serial data control pin used for functional control and communication in GPIO-limited applications. When the DC pin is used as a hardware device enable pin, a logic high signal on the DC pin enables the device, and a logic low signal on the DC pin disables the device. When the DC pin is used as the single-wire serial interface digital control pin, a combination of bit edges and the period between edges is used to communicate a variable length data word across the single wire. Each word is transmitted as a series of pulses, each pulse incrementing an internal data counter. A stop sequence consisting of an inactive period is used to latch the data word internally. The data word received is then used to set the value of the corresponding register for controlling specific function. The MIC2871 supports five writeable registers for controlling flash mode, torch mode, safety timer duration, safety timer threshold current, and low-battery threshold.

An address/data frame is used to improve protection against erroneous writes where communications are in error. When DC is in a low state and no data is detected for an extended period of time, the MIC2871 will automatically go into a low-power SHUTDOWN state, simultaneously resetting all internal registers to their default states.

FEN1 and FEN2

FEN1 and FEN2 are hardware enable pins for flash mode. FEN1 is logic-OR with FEN2. A logic low-to-high transition on either FEN1 pin or FEN2 pin can initiate the MIC2871 in flash mode. If FEN1 or FEN2 is left floating, it is pulled down internally by a built-in 1 μ A current source when the device is enabled. Flash mode is terminated when both FEN1 and FEN2 are pulled low or left floating, and the flash register is cleared.

FRSET

The flash mode maximum LED current level is programmed through the FRSET pin. A resistor connected from the FRSET pin to AGND2 set the maximum current in the flash mode. This pin can be grounded if the default flash mode current of 1A is desired. For the best current accuracy, 0.1% or smaller tolerance resistor for setting the maximum flash mode LED current is recommended. This pin cannot be left floating and the minimum resistance is limited to 17k Ω . The maximum flash mode current to maximum Torch mode current ratio is internally fixed as 4 to1.

Application Information

The MIC2871 can drive a high-current flash WLED in either flash mode or torch mode.

Boost Converter

The internal boost converter is turned on/off automatically when the LED driver is activated/de-activated without any exception.

The boost converter is an internally-compensated current-mode PWM boost converter running at 2MHz. It is for stepping up the supply voltage to a high enough value at the OUT pin to drive the LED current. If the supply voltage is high enough, the synchronous switch of the converter is then fully turned on. In this case, all the excessive voltage is dropped over the linear LED driver.

Flash Mode

The maximum current level in the flash mode is 1.2A. This current level can be adjusted through an external resistor connecting to the FRSET pin according to Equation 1:

$$I_{LED(MAX)} = \frac{20500}{R_{FRSET}} \quad \text{Eq. 1}$$

Alternatively, the default value of 1A is used when the FRSET pin is grounded.

The flash mode current can be initiated at this preset FRSET brightness level by asserting FEN1 or FEN2 pin HIGH, or by setting the flash control register (address 1), for the desired flash duration, subjected to the safety timeout setting. The flash mode current is terminated when the FEN1 and FEN2 pins are brought LOW and the flash register is cleared.

Flash mode current can be adjusted to a fraction of the maximum flash mode current level by selecting the desired percentage in the flash control register through the single-wire serial interface. The flash current is the product of the maximum flash current setting and the percentage selected in the flash register.

Torch Mode

By default, the maximum torch mode level is one-fourth (1/4) of the maximum flash mode current. The torch mode operation is activated by setting the torch control register (address 2) for the desired duration. The torch mode current is terminated when the torch register is cleared or when the configurable safety timer expires.

Like the flash mode current, the torch mode current can be tuned to a fraction of the maximum torch mode level by selecting the desired torch current level percentage in the torch control register (address 2) through the single-wire serial interface.

The torch current is the product of the maximum Torch current setting and the percentage selected in the torch register.

Configurable Safety Timer

The flash safety timeout feature automatically shuts down the LED current after the safety timer duration is expired if the programmed LED current exceeds a certain current threshold. Both the current threshold and the timer duration are programmable via the safety timer registers (addresses 3 and 5).

Low-Battery Voltage Detection (LBVD)

When the VIN voltage drops below the LBVD threshold (default = 3.6V) in flash or torch mode, the LED current driver is disabled. The LED driver can be resumed by toggling the corresponding input control signal. The LBVD threshold is adjustable thru the LBVD control register (address 4).

Overvoltage Protection

When the output voltage rises above the OVP threshold, MIC2871 is latched off automatically to avoid permanent damage to the IC. To clear the latched off condition, either power cycle the MIC2871 or assert the DC pin LOW.

Short-Circuit Detection

Each time before enabling the LED driver, the MIC2871 performs the short circuit test by driving the flash LED with a small (2mA typical) current for 200µs. If $(V_{OUT} - V_{LED}) < 1.7V$ at the end of the short-circuit test, the LED is considered to be shorted and MIC2871 will ignore the flash and/or torch mode command. Note that the short-circuit test is carried out every time prior to flash and torch mode but the result is not latched.

Thermal Shutdown

When the internal die temperature of MIC2871 reaches 155°C, the LED driver is disabled until the die temperature falls below 140°C.

Single-Wire Interface

The single-wire interface allows the use of a single multiplexed enable and data pin (DC) for control and communication in GPIO limited applications. The interface is implemented using a simple mechanism allowing any open drain or directly driven GPIO to control the MIC2871.

The MIC2871 uses the single-wire interface for simple command and control functions. The interface provides fast access to write only registers with protection features to avoid potentially erroneous data writes and improve robustness. When DC is in a low state and no data is detected for an extended period of time, the MIC2871 will automatically go into a low-power SHUTDOWN state, simultaneously resetting internal registers to default states.

Overview

The single-wire interface relies on a combination of bit edges and the period between edges in order to communicate across a single wire. Each word is transmitted as a series of pulses, with each pulse incrementing an internal data counter. A stop sequence consisting of an inactive period is used to latch the data word internally. An address and data framing format is used to improve protection against erroneous writes by enforcing address and data field lengths as well as the timing duration between them.

Timing is designed such that when communicating with a device using a low cost on chip oscillator, the worst case minimum and maximum conditions can be easily met within the wide operating range of the oscillator. Using this method guarantees that the device can always detect the delay introduced by the communication master.

Idle States and Error Conditions

In shutdown mode, the MIC2871 is in a reset condition with all functions off while consuming minimal power. Register settings are reset to default state when coming out of shutdown state. In idle mode, all register settings persist and all MIC2871 functions continue in their current state. [Table 1](#) summarises the difference between the two idle modes:

Table 1. Differences between Idle Modes

DC	Shutdown	Idle
	Low	High
I_{SUPPLY} (all functions off)	1 μ A	230 μ A
Register State	Default	Persist
Start-Up Time	1 μ s	100ns

Idle mode is entered automatically at the end of a communication frame by holding DC high for $\geq T_{END}$, by enabling the device by bringing DC high when in shutdown mode, or when an error is detected by the single-wire interface logic.

Shutdown mode can be entered at any time by pulling down DC for $\geq T_{END}$, discarding any current communication and resetting the internal registers. If a communication is received before the shutdown period but after the T_{LAT} period, the communication is discarded. This state is also used to create an internal error state to avoid erroneously latching data where the communication process cannot be serviced in time. Additionally, each register has a maximum value associated with it. If the number of bits clocked in exceeds the maximum value for the register, the data is assumed to be in error and the data is discarded.

Figure 2. Abort, Shutdown, and Idle Timing Waveforms

Communication Details

The serial interface requires delimiters to indicate the start of frame, data as a series of pulses, and end of frame indicated by a lack of activity. The start of frame is the first high to low transition of DC when in idle mode. The first rising edge resets the internal data counter to 0.

Figure 3. Data Word Pulse Timing

A pulse is delimited by the signal first going below V_L and then above V_H within the latch timeout T_{LAT} . During this transition, minimum on (T_{ON}) and off (T_{OFF}) periods are observed to improve tolerance to glitches. Each rising edge increments the internal data register. Data is automatically latched into internal shadow address and data registers after an inactivity period of $>T_{LAT}$.

To send register write commands, the address and data are entered in series as two data words using the above pattern, with the second word starting after the first latch period has expired. After the second word is entered, the IDLE command should be issued by leaving the DC pins high for $\geq T_{END}$.

After receiving the stop sequence, the internal registers decode and update cycle is started, with the shadow register values being transferred to the decoder. Figure 4 shows an example of entering a write of data 5 to address 3.

ADDRESS/DATA FRAME

Figure 4. Communication Timing Example of Entering Write for Data 5 to Address 3

Only correctly formatted address/data combination will be treated as a valid frame and processed by the MIC2871. Any other input, such as a single data word followed by T_{END} , or three successive data words will be discarded by the target hardware as an erroneous entry. Additionally, any register write to either an invalid register or with invalid register data will also be discarded.

MIC2871 Registers

The MIC2871 supports five writeable registers for controlling the torch and the flash modes of operation as shown in Table 2. Note that register addressing starts at 1. Writing any value above the maximum value shown for each registers will cause an invalid data error and the frame will be discarded.

Table 2. Five Writable Registers of MIC2871

Address	Name	Max. Value	Description
1	FEN/FCUR	31	Flash Enable/Current
2	TEN/TCUR	31	Torch Enable/Current
3	STDUR	7	Safety Timer Duration
4	LB_TH	9	Low Battery Voltage Detection Threshold
5	ST_TH	5	Safety Timer Threshold

Flash Current Register (FEN/FCUR: default 0)

The flash current register enables and sets the flash mode current level. Valid values are 0 to 31; values 0 – 15 will set the flash current without enabling the flash (such that it can be triggered externally), values 16 – 31 will set the flash current and enable the flash. The flash current register maps into the internal FEN and FCUR registers as shown in the table below. Table 3 describes the relationship between the flash current as a percentage of maximum current, and the FCUR register setting.

Table 3. Flash Current Register Mapping into Internal FEN and FCUR Registers, and Relationship between Flash Current as % of Maximum Current and the FCUR Register Setting

Value		FEN/FCUR[4:0]	
Dec.	Binary	FEN[4]	FCUR[3:0] % of I _{MAX}
0	00000	0	100.00
1	00001	0	88.96
2	00010	0	79.04

13	01101	0	22.40
14	01110	0	20.00
15	01111	0	17.92
16	10000	1	100.00
17	10001	1	88.96
18	10010	1	79.04
19	10011	1	70.72
20	10100	1	63.04
21	10101	1	56.00
22	10110	1	49.92
23	10111	1	44.64
24	11000	1	39.68
25	11001	1	35.52
26	11010	1	31.68
27	11011	1	28.16
28	11100	1	25.12
29	11101	1	22.40
30	11110	1	20.00
31	11111	1	17.92

Torch Current Register (TEN/TCUR: default 0)

The torch current register enables and sets the torch mode current level. Valid values are 0 to 31; values 0 – 15 will set the torch current without enabling the torch (such that it can be triggered by setting the internal TEN register value to 1), values 16 – 31 will set the torch current and enable the torch. A value of 0 at the internal TEN register will disable the torch. The torch current register maps into the internal TEN and TCUR registers as shown in [Table 4](#). The table also describes the relationship between the torch current as a percentage of maximum current, and the TCUR register setting.

Table 4. Torch Current Register Mapping into Internal T_{EN} and T_{CUR} Registers, and Relationship between Torch Current as % of Maximum Current and the T_{CUR} Register Setting

Value		T _{EN} /T _{CUR} [4:0]	
Dec.	Binary	T _{EN} [4]	T _{CUR} [3:0] % of I _{MAX}
0	00000	0	100.00
1	00001	0	88.96

6	110	110	1093.75
7	111	111	1250

Low-Battery Threshold Register (LB_TH: default 7)

The LB_TH register sets the supply threshold voltage below which the internal low battery flag is asserted and flash functions are inhibited. Table 6 shows the threshold values that correspond to the register settings. Setting 0 is reserved for disabling the function, and settings between 1 and 9 inclusively enable and set the LB_TH value between 3.0V and 3.8V with 100mV resolution.

Table 6. Low-Battery Threshold Register Setting and Supply Threshold Voltage

Value		LB_TH[3:0]	V _{BAT} Threshold (V)
Dec.	Binary		
0	0000	0000	Disabled
1	0001	0001	3.0
2	0010	0010	3.1
3	0011	0011	3.2
4	0100	0100	3.3
5	0101	0101	3.4
6	0110	0110	3.5
7	0111	0111	3.6
8	1000	1000	3.7
9	1001	1001	3.8

Safety Timer Threshold Current Register (ST_TH: default 4)

Safety timer threshold current determines the amount of LED current flowing through the external LED before the internal LED safety timer is activated. Setting ST_TH to 0 disables the safety timer function, and setting the register to values 1 to 5 set the safety time threshold current 100mA to 300mA in 50mA steps.

Table 7. Safety Timer Threshold Current Register Setting and Safety Timer Threshold Current

Value		ST_TH[2:0]	Safety Timer Threshold Current (mA)
Dec.	Binary		
0	000	000	Disabled
1	001	001	100mA
2	010	010	150mA
3	011	011	200mA
4	100	100	250mA
5	101	101	300mA

Component Selection

Inductor

Inductor selection is a balance between efficiency, stability, cost, size, and rated current. Since the boost converter is compensated internally, the recommended inductance of L is limited from $1\mu\text{H}$ to $2.2\mu\text{H}$ to ensure system stability. It is usually a good balance between these considerations.

A large inductance value reduces the peak-to-peak inductor ripple current hence the output ripple voltage and the LED ripple current. This also reduces both the DC loss and the transition loss at the same inductor's DC resistance (DCR). However, the DCR of an inductor usually increases with the inductance in the same package size. This is due to the longer windings required for an increase in inductance. Since the majority of the input current passes through the inductor, the higher the DCR the lower the efficiency is, and more significantly at higher load currents. On the other hand, inductor with smaller DCR but the same inductance usually has a larger size. The saturation current rating of the selected inductor must be higher than the maximum peak inductor current to be encountered and should be at least 20% to 30% higher than the average inductor current at maximum output current.

Input Capacitor

A ceramic capacitor of $2.2\mu\text{F}$ or larger with low ESR is recommended to reduce the input voltage ripple to ensure a clean supply voltage for the device. The input capacitor should be placed as close as possible to the MIC2871 VIN pin with short trace for good noise performance. X5R or X7R type ceramic capacitors are recommended for better tolerance over temperature. The Y5V and Z5U type temperature rating ceramic capacitors are not recommended due to their large reduction in capacitance over temperature and increased resistance at high frequencies. These reduce their ability to filter out high-frequency noise. The rated voltage of the input capacitor should be at least 20% higher than the maximum operating input voltage over the operating temperature range.

Output Capacitor

Output capacitor selection is also a trade-off between performance, size, and cost. Increasing output capacitor will lead to an improved transient response, however, the size and cost also increase. The output capacitor is preferred in the range of $2.2\mu\text{F}$ to $10\mu\text{F}$ with ESR from $10\text{m}\Omega$ to $50\text{m}\Omega$. X5R or X7R type ceramic capacitors are recommended for better tolerance over temperature.

The Y5V and Z5U type ceramic capacitors are not recommended due to their wide variation in capacitance over temperature and increased resistance at high frequencies. The rated voltage of the output capacitor should be at least 20% higher than the maximum operating output voltage over the operating temperature range.

FRSET Resistor

Since FRSET resistor is used for setting the maximum LED current, resistor type with 0.1% tolerance is recommended for more accurate maximum LED current setting.

Power Dissipation Consideration

As with all power devices, the ultimate current rating of the output is limited by the thermal properties of the device package and the PCB on which the device is mounted. There is a simple, Ω 's law type relationship between thermal resistance, power dissipation and temperature which are analogous to an electrical circuit:

Figure 5. Series Electrical Resistance Circuit

From this simple circuit we can calculate V_X if we know I_{SOURCE} , V_Z and the resistor values, R_{XY} and R_{YZ} using Equation 2:

$$V_X = I_{SOURCE} \times (R_{XY} + R_{YZ}) + V_Z \tag{Eq. 2}$$

Thermal circuits can be considered using this same rule and can be drawn similarly by replacing current sources with power dissipation (in watts), resistance with thermal resistance (in $^{\circ}C/W$) and voltage sources with temperature (in $^{\circ}C$).

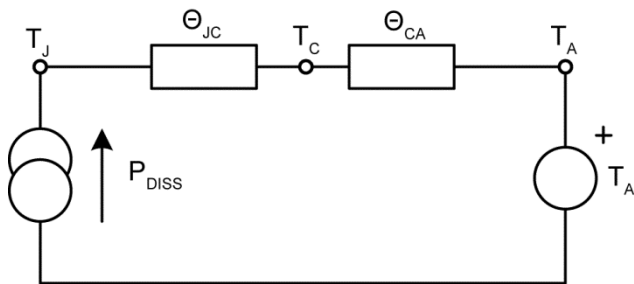

Figure 6. Series Thermal Resistance Circuit

Now replacing the variables in Equation 2, we can find the junction temperature (T_J) from the power dissipation, ambient temperature and the known thermal resistance of the PCB (θ_{CA}) and the package (θ_{JC}).

$$T_J = P_{DISS} \times (\theta_{JC} + \theta_{CA}) + T_A \tag{Eq. 3}$$

As can be seen in the diagram, total thermal resistance $\theta_{JA} = \theta_{JC} + \theta_{CA}$. Hence this can also be written as in Equation 4:

$$T_J = P_{DISS} \times (\theta_{JA}) + T_A \tag{Eq. 4}$$

Since effectively all of the power losses (minus the inductor losses) in the converter are dissipated within the MIC2871 package, P_{DISS} can be calculated thus:

$$\text{Linear Mode: } P_{DISS} = [P_{OUT} \times \left(\frac{1}{\eta} - 1\right)] - I_{OUT}^2 \times DCR \tag{Eq. 5}$$

$$\text{Boost Mode: } P_{DISS} = [P_{OUT} \times \left(\frac{1}{\eta} - 1\right)] - \left(\frac{I_{OUT}}{1-D}\right)^2 \times DCR \tag{Eq. 6}$$

$$\text{Duty Cycle in Boost Mode: } D = \frac{V_{OUT} - V_{IN}}{V_{OUT}} \tag{Eq. 7}$$

where:

η = Efficiency taken from efficiency curves and DCR = inductor DCR. θ_{JC} and θ_{JA} are found in the operating ratings section of the datasheet.

Where the real board area differs from 1" square, θ_{CA} (the PCB thermal resistance) values for various PCB copper areas can be taken from Figure 7. Figure 7 is taken from *Designing with Low Dropout Voltage Regulators* available from the Micrel website ("LDO Application Hints").

Figure 7. Graph to Determine PC Board Area for a Given PCB Thermal Resistance

Figure 7 shows the total area of a round or square pad, centered on the device. The solid trace represents the area of a square, single-sided, horizontal, solder-masked, copper PC board trace heat sink, measured in square millimeters. No airflow is assumed. The dashed line shows PC boards trace heat sink covered in black oil-based paint and with 1.3m/sec (250 feet per minute) airflow. This approaches a "best case" pad heat sink. Conservative design dictates using the solid trace data, which indicates a maximum pad size of 5000 mm² is needed. This is a pad 71mm by 71mm (2.8 inches per side).

PCB Layout Guidelines

PCB layout is critical to achieve reliable, stable and efficient performance. A ground plane is required to control EMI and minimize the inductance in power, signal and return paths. The following guidelines should be followed to ensure proper operation of the device:

IC (Integrated Circuit)

- Place the IC close to the point-of-load (in this case, the flash LED).
- Use fat traces to route the input and output power lines.
- Analog grounds (AGND1 and AGND2) and power grounds (PGND1 and PGND2) should be kept separate and connected at a single location.
- The exposed pad (EPAD) on the bottom of the IC must be connected to the analog grounds AGND2 of the IC.
- 8 to 12 thermal vias must be placed on the PCB pad for exposed pad and connected it to the ground plane to ensure a good PCB thermal resistance can be achieved.

VIN Decoupling Capacitor

- The VIN decoupling capacitor must be placed close to the VIN pin of the IC and preferably connected directly to the pin and not through any via. The capacitor must be located right at the IC.
- The VIN decoupling capacitor should be connected to analog ground (AGND2).
- The VIN terminal is noise sensitive and the placement of capacitor is very critical.

Inductor

- Keep both the inductor connections to the switch node (SW) and input power line short and wide enough to handle the switching current. Keep the areas of the switching current loops small to minimize the EMI problem.
- Do not route any digital lines underneath or close to the inductor.
- Keep the switch node (SW) away from the noise sensitive pins.
- To minimize noise, place a ground plane underneath the inductor.

Output Capacitor

- Use wide and short traces to connect the output capacitor to the OUT and PGND1 pins.
- Place several vias to the ground plane close to the output capacitor ground terminal.
- Use either X5R or X7R temperature rating ceramic capacitors. Do not use Y5V or Z5U type ceramic capacitors.

Flash LED

- Use wide and short trace to connect the LED anode to the OUT pin.
- Use wide and short trace to connect the LED cathode to the LED pin.
- Make sure that the LED's PCB land pattern can provide sufficient PCB pad heat sink to the flash LED.

FRSET Resistor

The FRSET resistor should be placed close to the FRSET pin and connected to AGND2.
