

ISL59420/21EVAL1 Evaluation Board User's Guide

Application Note

August 10, 2005

AN1187.1

Introduction

The ISL59420/21EVAL1 evaluation board contains all the circuitry needed to characterize critical performance parameters of the ISL59420, ISL59421 single 2:1 MUX-amplifier, over a variety of applications.

The ISL59420, ISL59421 are single-output, gain-selectable 2:1 MUX-amps. The unity-gain bandwidths are 400MHz for the ISL59420 and 900MHz for the ISL59421. Each contain a common set of logic inputs for channel selection (S) three-state output control (HIZ) and an enable control input that powers down the device (\overline{EN}) .

The evaluation board circuit and layout is optimized for either 50Ω or 75Ω terminations, and implements a basic single 2:1 video MUX-amp. The board is supplied with 75Ω input signal terminations and a 75Ω back-termination resistor on each of the 3 outputs, making it suitable for driving video cable. The user has the option of replacing the 75Ω resistors with 50Ω resistors for other applications. The control lines contain 50Ω resistors to match the 50Ω output impedance of high speed pulse generators. Control line termination resistors are recommended for rise and fall times under 10ns to minimize unwanted transients. If DC is used for the control logic, the resistors may be removed; or the applied DC voltage can be reduced to 2.5V to reduce the dissipation in the termination resistor.

The layout contains component options to include an output series resistor (R_S) followed by a parallel resistor (R_L) capacitor (C_L) network to ground. This option allows the user to select several different output configurations. Examples are shown in Figures 2A, 2B, and 2C. The evaluation board is supplied with the 75 Ω back termination resistors shown in Figure 2C.

Amplifier Performance and Output Configurations

The ISL59420, ISL59421 output amplifier is externally gainselectable with the non-inverting input directly coupled to the 2:1 MUX output. The inverting input is pinned out to the evaluation board. Resistor R_F is set to the value shown in Figure 2D, and in conjunction with the amplifier internal capacitance, provides optimum frequency response with minimal gain peaking. The output amplifier is ideally suited for driving high impedance high speed selectable-gain buffers when gain compensation is needed. GBW decreases slightly at the lower output load impedances typical of backterminated cable driving applications. Reference data sheets for additional performance data.

High Frequency Layout Considerations

At frequencies of 500MHz and higher, circuit board layout may limit performance. The following layout guidelines are implemented on the evaluation board:

- Signal I/O lines are the same lengths and widths to match propagation delay and trace parasitics.
- No series connected vias are used in signal I/O lines, as they can add unwanted inductance.
- Signal trace lengths are minimized to reduce transmission line effects and the need for strip-line tuning of the signal traces.
- High frequency decoupling caps are placed as close to the device power supply pin as possible without series vias between the capacitor and the device pin.

Power Sequencing

Proper power supply sequencing is -V first, then +V. In addition, the +V and -V supply pin voltage rate-of-rise must be limited to $\pm 1V/\mu$ s or less. The evaluation board contains parallel-connected low V_{ON} Schottky diodes on each supply terminal to minimize the risk of latch up due to incorrect sequencing. In addition, extra 10µF decoupling capacitors are added to each supply to aid in reducing the applied voltage rate-of-rise.
