

## ACPI Regulator/Controller for Dual Channel DDR Memory Systems

The ISL6537 provides a complete ACPI compliant power solution for up to 4 DIMM dual channel DDR/DDR2 Memory systems. Included are both a synchronous buck controller to supply  $V_{DDQ}$  during S0/S1 and S3 states. During S0/S1 state, a fully integrated sink-source regulator generates an accurate ( $V_{DDQ}/2$ ) high current  $V_{TT}$  voltage without the need for a negative supply. A buffered version of the  $V_{DDQ}/2$  reference is provided as  $V_{REF}$ . Two LDO controllers are also integrated for the GMCH core voltage regulation and for the GMCH and CPU  $V_{TT}$  termination voltage regulation.

The switching PWM controller drives two N-Channel MOSFETs in a synchronous-rectified buck converter topology. The synchronous buck converter uses voltage-mode control with fast transient response. The switching regulator provides a maximum static regulation tolerance of  $\pm 2\%$  over line, load, and temperature ranges. The output is user-adjustable by means of external resistors down to 0.8V.

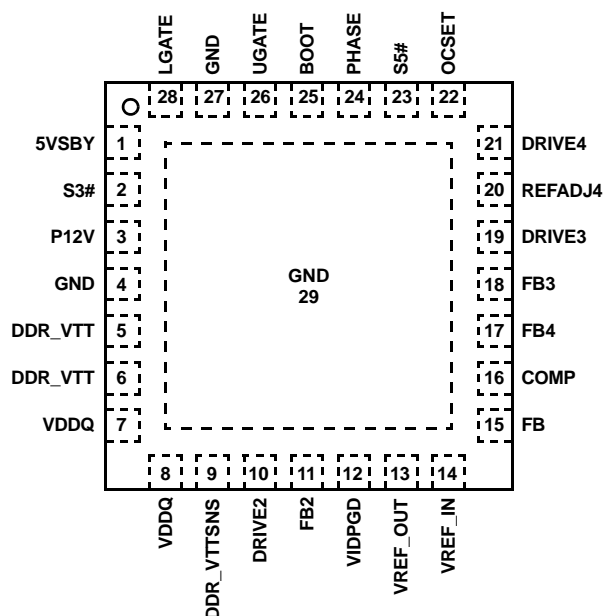

An integrated soft-start feature brings all outputs into regulation in a controlled manner when returning to S0/S1 state from any sleep state. During S0 the VIDPGD signal indicates that the GMCH and CPU  $V_{TT}$  termination voltage is within spec and operational.

Each output is monitored for undervoltage events. The switching regulator also has overvoltage and overcurrent protection. Thermal shutdown is integrated.

## Pinout

TOP VIEW

## Features

- Generates 4 Regulated Voltages
  - Synchronous Buck PWM Controller for DDR  $V_{DDQ}$
  - 3A Integrated Sink/Source Linear Regulator with Accurate  $V_{DDQ}/2$  Divider Reference for DDR  $V_{TT}$
  - LDO Regulator for GMCH Core
  - LDO Regulator for CPU/GMCH  $V_{TT}$  Termination
- ACPI Compliant Sleep State Control
- Glitch-free Transitions During State Changes
- Integrated  $V_{REF}$  Buffer
- PWM Controller Drives Low Cost N-Channel MOSFETs
- 250kHz Constant Frequency Operation
- Tight Output Voltage Regulation
  - All Outputs:  $\pm 2\%$  Over Temperature
- Fully-Adjustable Outputs with Wide Voltage Range: Down to 0.8V supports DDR and DDR2 Specifications
- Simple Single-Loop Voltage-Mode PWM Control Design
- Fast PWM Converter Transient Response
- Under and Overvoltage Monitoring on All Outputs
- OCF on the Switching Regulator
- Integrated Thermal Shutdown Protection
- Pb-Free Plus Anneal Available (RoHS Compliant)

## Applications

- Single and Dual Channel DDR Memory Power Systems in ACPI Compliant PCs
- Graphics Cards - GPU and Memory Supplies
- ASIC Power Supplies
- Embedded Processor and I/O Supplies
- DSP Supplies

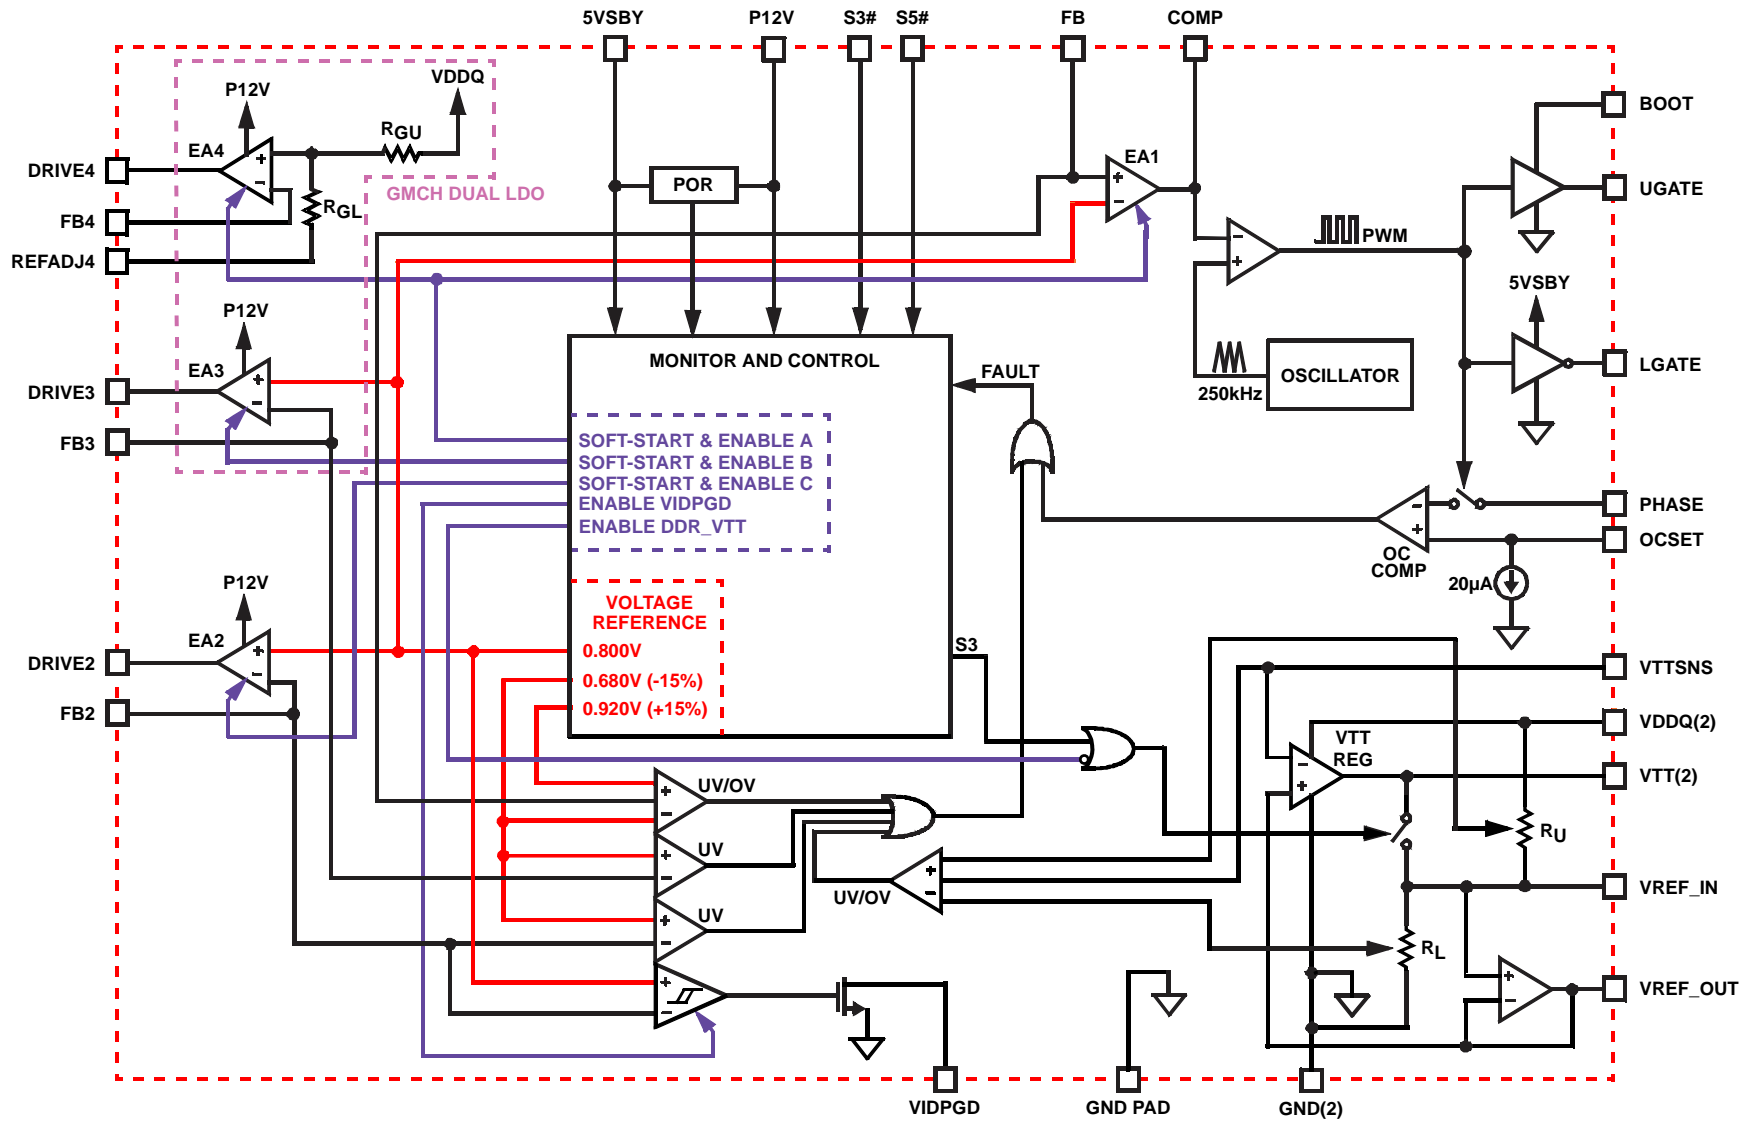

## Ordering Information

PART NUMBER	PART MARKING	TEMP. RANGE (°C)	PACKAGE	PKG. DWG. #
ISL6537CR	ISL6537CR	0 to +70	28 Ld 6x6 QFN	L28.6x6
ISL6537CRZ (See Note)	ISL6537CRZ	0 to +70	28 Ld 6x6 QFN (Pb-free)	L28.6x6

\*Add "-T" suffix to part number for tape and reel packaging.

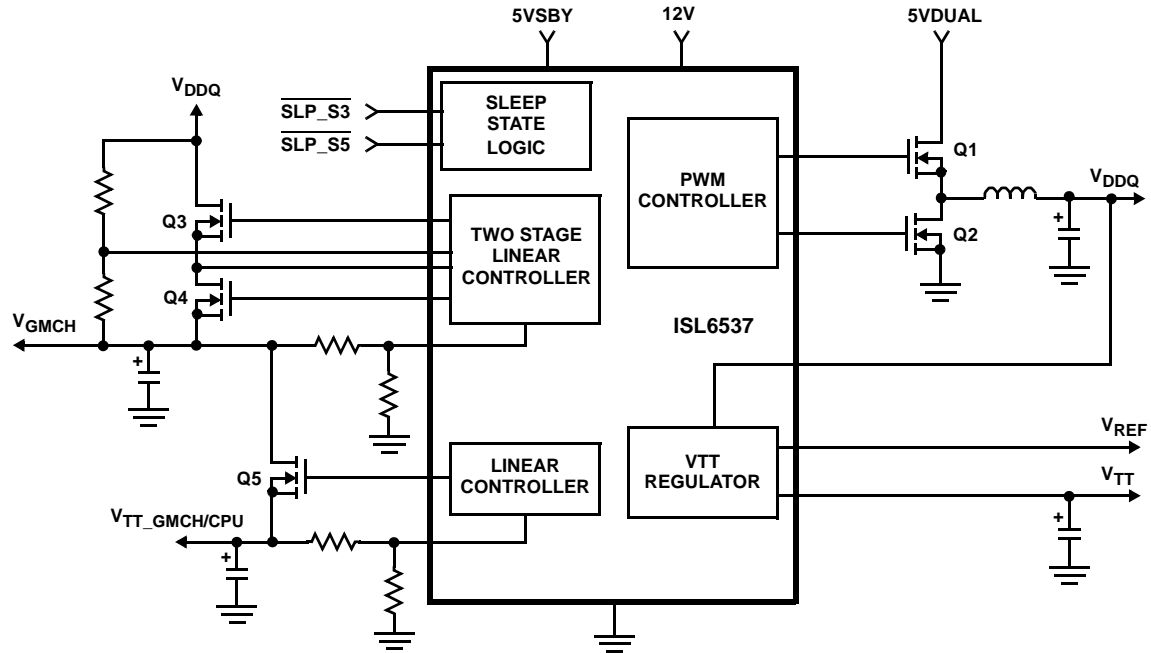

NOTE: Intersil Pb-free plus anneal products employ special Pb-free material sets; molding compounds/die attach materials and 100% matte tin plate termination finish, which are RoHS compliant and compatible with both SnPb and Pb-free soldering operations. Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

ISL6537

## Simplified Power System Diagram

## Typical Application

**Absolute Maximum Ratings**

5VSBY ..... GND - 0.3V to +7V  
P12V ..... GND - 0.3V to +14V  
Absolute Boot Voltage,  $V_{BOOT}$  ..... +15.0V  
Upper Driver Supply Voltage,  $V_{BOOT} - V_{PHASE}$  ..... 7.0V (DC)  
8.0V (<10ns Pulse Width, 10 $\mu$ J)  
All other Pins ..... GND - 0.3V to 5VCC + 0.3V  
ESD Classification ..... Class 2

**Thermal Information**

Thermal Resistance  $\theta_{JA}$  (°C/W)  $\theta_{JC}$  (°C/W)  
QFN Package (Notes 1, 2) ..... 32 5  
Maximum Junction Temperature (Plastic Package) ..... +150°C  
Maximum Storage Temperature Range ..... -65°C to +150°C  
Pb-free reflow profile ..... see link below  
<http://www.intersil.com/pbfree/Pb-FreeReflow.asp>

**Recommended Operating Conditions**

Supply Voltage on 5VSBY ..... +5V  $\pm$ 10%  
Supply Voltage on P12V ..... +12V  $\pm$ 10%  
Ambient Temperature Range ..... 0°C to +70°C  
Junction Temperature Range ..... 0°C to +125°C

**CAUTION:** Do not operate at or near the maximum ratings listed for extended periods of time. Exposure to such conditions may adversely impact product reliability and result in failures not covered by warranty.

**NOTES:**

1.  $\theta_{JA}$  is measured in free air with the component mounted on a high effective thermal conductivity test board with "direct attach" features. See Tech Brief TB379.
2. For  $\theta_{JC}$ , the "case temp" location is the center of the exposed metal pad on the package underside.

## Functional Pin Description

### 5VSBY (Pin 1)

5VSBY is the bias supply of the ISL6537. It is typically connected to the 5V standby rail of an ATX power supply. During S4/S5 sleep states the ISL6537 enters a reduced power mode and draws less than 1mA ( $I_{CC\_S5}$ ) from the 5VSBY supply. The supply to 5VSBY should be locally bypassed using a 0.1μF capacitor.

### P12V (Pin 3)

The  $V_{TT}$  regulation circuit and the Linear Drivers are powered by P12V. P12V is not required during S3/S4/S5 operation. P12V is typically connected to the +12V rail of an ATX power supply.

### GND (Pins 4, 27, 29)

The GND terminals of the ISL6537 provide the return path for the  $V_{TT}$  LDO, and switching MOSFET gate drivers. High ground currents are conducted directly through the exposed paddle of the QFN package which must be electrically connected to the ground plane through a path as low in inductance as possible.

### UGATE (Pin 26)

Connect this pin to the upper MOSFET's gate. This pin provides the PWM-controlled gate drive for the upper MOSFET. This pin is also monitored by the adaptive shoot-through protection circuitry to determine when the upper MOSFET has turned off. Do not insert any circuitry between this pin and the gate of the upper MOSFET, as it may interfere with the internal adaptive shoot-through protection circuitry and render it ineffective.

### LGATE (Pin 28)

Connect this pin to the lower MOSFET's gate. This pin provides the PWM-controlled gate drive for the lower MOSFET. This pin is also monitored by the adaptive shoot-through protection circuitry to determine when the lower MOSFET has turned off. Do not insert any circuitry between this pin and the gate of the lower MOSFET, as it may interfere with the internal adaptive shoot-through protection circuitry and render it ineffective.

### FB (Pin 15) and COMP (Pin 16)

The  $V_{DDQ}$  switching regulator employs a single voltage control loop. FB is the negative input to the voltage loop error amplifier. The  $V_{DDQ}$  output voltage is set by an external resistor divider connected to FB. With a properly selected divider,  $V_{DDQ}$  can be set to any voltage between the power rail (reduced by converter losses) and the 0.8V reference. Loop compensation is achieved by connecting an AC network across COMP and FB.

The FB pin is also monitored for under and overvoltage events.

### PHASE (Pin 24)

Connect this pin to the upper MOSFET's source. This pin is used to monitor the voltage drop across the upper MOSFET for overcurrent protection.

### OCSET (Pin 22)

Connect a resistor ( $R_{OCSET}$ ) from this pin to the drain of the upper MOSFET.  $R_{OCSET}$ , an internal 20μA current source ( $I_{OCSET}$ ), and the upper MOSFET on-resistance ( $r_{DS(ON)}$ ) set the converter overcurrent (OC) trip point according to the following equation:

$$I_{PEAK} = \frac{I_{OCSET} \times R_{OCSET}}{r_{DS(ON)}} \quad (\text{EQ. 1})$$

An overcurrent trip cycles the soft-start function.

### VDDQ (Pins 7, 8)

The VDDQ pins should be connected externally together to the regulated  $V_{DDQ}$  output. During S0/S1 states, the VDDQ pins serve as inputs to the  $V_{TT}$  regulator and to the  $V_{TT}$  Reference precision divider.

### DDR\_VTT (Pins 5, 6)

The DDR\_VTT pins should be connect externally together. During S0/S1 states, the DDR\_VTT pins serve as the outputs of the  $V_{TT}$  linear regulator. During S3 state, the  $V_{TT}$  regulator is disabled.

### DDR\_VTTSNS (Pin 9)

VTTSNS is used as the feedback for control of the  $V_{TT}$  linear regulator. Connect this pin to the  $V_{TT}$  output at the physical point of desired regulation.

### VREF\_OUT (Pin 13)

VREF\_OUT is a buffered version of  $V_{TT}$  and also acts as the reference voltage for the  $V_{TT}$  linear regulator. It is recommended that a minimum capacitance of 0.1μF is connected between  $V_{DDQ}$  and VREF\_OUT and also between VREF\_OUT and ground for proper operation.

### VREF\_IN (Pin 14)

A capacitor,  $C_{SS}$ , connected between VREF\_IN and ground is required. This capacitor and the parallel combination of the Upper and Lower Divider Impedance ( $R_U || R_L$ ), sets the time constant for the start up ramp when transitioning from S3/S4/S5 to S0/S1/S2.

The minimum value for  $C_{SS}$  can be found through the following equation:

$$C_{SS} > \frac{C_{VTTOUT} \cdot V_{DDQ}}{10 \cdot 2A \cdot R_U || R_L} \quad (\text{EQ. 2})$$

The calculated capacitance,  $C_{SS}$ , will charge the output capacitor bank on the  $V_{TT}$  rail in a controlled manner without reaching the current limit of the  $V_{TT}$  LDO.

**BOOT (Pin 25)**

This pin provides ground referenced bias voltage to the upper MOSFET driver. A bootstrap circuit is used to create a voltage suitable to drive a logic-level N-channel MOSFET.

**FB2 (Pin 11)**

Connect the output of the  $V_{TT\_GMCH/CPU}$  linear regulator to this pin through a properly sized resistor divider. The voltage at this pin is regulated to 0.8V. This pin is monitored for undervoltage events.

**DRIVE2 (Pin 10)**

This pin provides the gate voltage for the  $V_{TT\_GMCH/CPU}$  linear regulator pass transistor. Connect this pin to the gate terminal of an external N-Channel MOSFET transistor.

**FB3 (Pin 18)**

Connect the output of the lower  $V_{GMCH}$  linear regulator to this pin through a properly sized resistor divider. The voltage at this pin is regulated to 0.8V. This pin is monitored for undervoltage events.

**DRIVE3 (Pin 19)**

This pin provides the gate voltage for the lower  $V_{GMCH}$  linear regulator pass transistor. Connect this pin to the gate terminal of an external N-Channel MOSFET transistor.

**FB4 (Pin 20)**

Connect the output of the upper  $V_{GMCH}$  linear regulator to this pin. The voltage at this pin is regulated via the RAFADJ4 pin.

**DRIVE4 (Pin 21)**

This pin provides the gate voltage for the upper  $V_{GMCH}$  linear regulator pass transistor. Connect this pin to the gate terminal of an external N-Channel MOSFET transistor.

**REFADJ4 (Pin 20)**

This pin controls the reference for the upper  $V_{GMCH}$  linear regulator. To insure that both upper and lower pass transistors dissipate the same power, tie this pin to the  $V_{GMCH}$  output rail.

**VIDPGD (Pin 12)**

The VIDPGD pin is an open-drain logic output that changes to a logic low if the  $V_{TT\_GMCH/CPU}$  linear regulator is out of regulation in S0/S1/S2 state. VIDPGD will always be low in any state other than S0/S1/S2.

**S5# (Pin 23)**

This pin accepts the SLP\_S5# sleep state signal.

**S3# (Pin 2)**

This pin accepts the SLP\_S3# sleep state signal.

**Functional Description****Overview**

The ISL6537 provides complete control, drive, protection and ACPI compliance for a regulator powering DDR memory systems and the GMCH core and GMCH/CPU termination rails. It is primarily designed for computer applications powered from an ATX power supply.

A 250kHz Synchronous Buck Regulator with a precision 0.8V reference provides the proper Core voltage to the system memory of the computer. An internal LDO regulator with the ability to both sink and source current and an externally available buffered reference that tracks the  $V_{DDQ}$  output by 50% provides the  $V_{TT}$  termination voltage.

A dual stage LDO controller provides the GMCH core voltage. A third LDO controller is included for the regulation of the GMCH/CPU termination rail.

ACPI compliance is realized through the SLP\_S3 and SLP\_S5 sleep signals and through monitoring of the 12V ATX bus.

**Initialization**

The ISL6537 automatically initializes upon receipt of input power. Special sequencing of the input supplies is not necessary. The Power-On Reset (POR) function continually monitors the input bias supply voltages. The POR monitors the bias voltage at the 5VSBY and P12V pins. The POR function initiates soft-start operation after the bias supply voltages exceed their POR thresholds.

**ACPI State Transitions**

Figure 1 shows how the individual regulators are controlled during all state transitions. All references to timing in this section are in reference to Figure 1.

**Cold Start (S4/S5 to S0 Transition)**

At the onset of a mechanical start, time  $t_0$  in Figure 1, the ISL6537 receives its bias voltage from the 5V Standby bus (5VSBY). Once the 5VSBY rail has exceeded the POR threshold, the ISL6537 will remain in an internal S5 state until both the SLP\_S3 and SLP\_S5 signal have transitioned high and the 12V POR threshold has been exceeded by the +12V rail from the ATX, which occurs at time  $t_1$ .

Once all of these conditions are met, the PWM error amplifier will first be reset by internally shorting the COMP pin to the FB pin. This reset lasts for three soft-start cycles, which is typically 24ms (one soft-start cycle is typically 8.2ms). The digital soft-start sequence will then begin. Each regulator is enabled and soft-started according to a preset sequence.

At time  $t_2$ , the 3 soft-start cycle reset has ended and the  $V_{DDQ\_DDR}$  rail and the upper  $V_{GMCH}$  LDO are digitally soft-started.

FIGURE 1. ISL6537 TIMING DIAGRAM

The digital soft-start for the PWM regulator is accomplished by clamping the error amplifier reference input to a level proportional to the internal digital soft-start voltage. As the soft-start voltage slews up, the PWM comparator generates PHASE pulses of increasing width that charge the output capacitor(s). This method provides a rapid and controlled output voltage rise.

The linear regulators, with the exception of the internal  $V_{TT\_DDR}$  LDO, are soft-started in a similar manner. The error amplifier reference is clamped to the internal digital soft-start voltage. As the soft-start voltage ramps up, the respective DRIVE pin voltages increase, thus enhancing the N-MOSFETs and charging the output capacitors in a controlled manner.

At time  $t_3$ , the  $V_{DDQ\_DDR}$  and upper  $V_{GMCH}$  LDO output rails are in regulation and the lower  $V_{GMCH}$  LDO is soft-started. At time  $t_4$ , the  $V_{GMCH}$  rail is in regulation and the  $V_{TT\_GMCH/CPU}$  linear regulator is soft-started. At time  $t_5$ , the  $V_{TT\_GMCH/CPU}$  rail is in regulation and the  $V_{TT\_DDR}$  internal regulator is soft-started.

The  $V_{TT\_DDR}$  LDO soft-starts in a manner unlike the other regulators. When the  $V_{TT\_DDR}$  regulator is disabled, the reference is internally shorted to the  $V_{TT\_DDR}$  output. This allows the termination voltage to float during the S3 sleep state. When the ISL6537 enables the  $V_{TT\_DDR}$  regulator or enters S0 state from a sleep state, this short is released and the internal divide down resistors which set the  $V_{TT\_DDR}$  voltage to 50% of  $V_{DDQ\_DDR}$  will provide a controlled voltage rise on the capacitor that is tied to the  $V_{REF\_IN}$  pin. The voltage on this capacitor is the reference for the  $V_{TT\_DDR}$  regulator and the output will track it as it settles to 50% of the  $V_{DDQ}$  voltage. The combination of the internal resistors and the  $V_{REF\_IN}$  capacitor will determine the rise time of the  $V_{TT\_DDR}$  regulator (see the Functional Pin Description section for proper sizing of the  $V_{REF\_IN}$  capacitor).

At time  $t_6$ , a full soft-start cycle has passed from the time that the  $V_{TT\_DDR}$  regulator was enabled. At this time the VIDPGD comparator is enabled. Once enabled if the  $V_{TT\_GMCH/CPU}$  output is within regulation, the VIDPGD pin will be forced to a high impedance state.

#### Active to Sleep (S0 to S3 Transition)

When SLP\_S3 goes LOW with SLP\_S5 still HIGH, the ISL6537 will disable all the regulators except for the  $V_{DDQ}$  regulator, which is continually supplied by the 5VDUAL rail. VIDPGD will also transition LOW. When  $V_{TT}$  is disabled, the internal reference for the  $V_{TT}$  regulator is internally shorted to the  $V_{TT}$  rail. This allows the  $V_{TT}$  rail to float. When floating, the voltage on the  $V_{TT}$  rail will depend on the leakage characteristics of the memory and MCH I/O pins. It is important to note that the  $V_{TT}$  rail may not bleed down to 0V. Figure 1 shows how the individual regulators are affected by the S3 state at time  $t_7$ .

#### Sleep to Active (S3 to S0 Transition)

When SLP\_S3 transitions from LOW to HIGH with SLP\_S5 held HIGH and after the 12V rail exceeds POR, the ISL6537 will initiate the soft-start sequence. This sequence is very similar to the mechanical start soft-start sequencing. The transition from S3 to S0 is represented in Figure 1 between times  $t_8$  and  $t_{14}$ .

At time  $t_8$ , the SLP\_S3 signal transitions HIGH. This enables the ATX, which brings up the 12V rail. At time  $t_9$ , the 12V rail has exceeded the POR threshold and the ISL6537 enters a reset mode that lasts for 3 soft-start cycles. At time  $t_{10}$ , the 3 soft-start cycle reset is ended and the individual regulators are enabled and soft-started in the same sequence as the mechanical cold start sequence, with the exception that the  $V_{DDQ}$  regulator is already enabled and in regulation.

#### Active to Shutdown (S0 to S5 Transition)

When the system transitions from active, S0, state to shutdown, S4/S5, state, the ISL6537 IC disables all regulators and forces the VIDPGD pin LOW. This transition is represented on Figure 1 at time  $t_{15}$ .

#### Fault Protection

The ISL6537 monitors the  $V_{DDQ}$  regulator for under and overvoltage events. The  $V_{DDQ}$  regulator also has overcurrent protection. The internal  $V_{TT\_DDR}$  LDO regulator is monitored for under and overvoltage events. All other regulators are monitored for undervoltage events.

An overvoltage event on either the  $V_{DDQ}$  or  $V_{TT\_DDR}$  regulator will cause an immediate shutdown of all regulators. This can only be cleared by toggling the SLP\_S5 signal such that the system enters the S5 sleep state and then transitions back to the active, S0, state.

If a regulator experiences any other fault condition (an undervoltage or an overcurrent on  $V_{DDQ}$ ), then that regulator, and only that regulator, will be disabled and an internal fault counter will be incremented by 1. If the disabled regulator is used as the input for another regulator, then that cascaded regulator will also experience a fault condition due to a loss of input. The cascaded regulator will be disabled and the fault counter incremented by 1.

At every fault occurrence, the internal fault counter is incremented by 1 and an internal Fault Reset Counter is cleared to zero. The Fault Reset Counter will increment once for every clock cycle (1 clock cycle is typically 1/250kHz, or 4 $\mu$ s). If the Fault Reset Counter reaches a count of 16384 before another fault occurs, then the Fault Counter is cleared to 0. If a fault occurs prior to the Fault Reset Counter reaching a count of 16384, then the Fault Reset Counter is set back to zero.

The ISL6537 will immediately shut down when the Fault Counter reaches a count of 4 when the system is restarting from an S5 state into the active, or S0, state. The ISL6537

will immediately shut down when the Fault Counter reaches a count of 5 at any other time.

The 16384 counts that are required to reset the Fault Reset Counter represent 8 soft-start cycles, as one soft-start cycle is 2048 clock cycles. This allows the ISL6537 to attempt at least one full soft-start sequence to restart the faulted regulators.

When attempting to restart a faulted regulator, the ISL6537 will follow the preset start up sequencing. If a regulator is already in regulation, then it will not be affected by the start up sequencing.

### ***V<sub>DDQ</sub> Overcurrent Protection***

The overcurrent function protects the switching converter from a shorted output by using the upper MOSFET on-resistance,  $r_{DS(ON)}$ , to monitor the current. This method enhances the converter's efficiency and reduces cost by eliminating a current sensing resistor.

The overcurrent function cycles the soft-start function in a hiccup mode to provide fault protection. A resistor ( $R_{OCSET}$ ) programs the overcurrent trip level (see Typical Application diagrams on pages 3 and 4). An internal 20 $\mu$ A (typical) current sink develops a voltage across  $R_{OCSET}$  that is referenced to the converter input voltage. When the voltage across the upper MOSFET (also referenced to the converter input voltage) exceeds the voltage across  $R_{OCSET}$ , the overcurrent function initiates a soft-start sequence. The initiation of soft-start may affect other regulators. The  $V_{TT\_DDR}$  regulator is directly affected as it receives its reference and input from  $V_{DDQ}$ .

The overcurrent function will trip at a peak inductor current ( $I_{PEAK}$ ) determined by:

$$I_{PEAK} = \frac{I_{OCSET} \times R_{OCSET}}{r_{DS(ON)}} \quad (EQ. 3)$$

where  $I_{OCSET}$  is the internal OCSET current source (20 $\mu$ A typical). The OC trip point varies mainly due to the MOSFET  $r_{DS(ON)}$  variations. To avoid overcurrent tripping in the normal operating load range, find the  $R_{OCSET}$  resistor from the equation above with:

1. The maximum  $r_{DS(ON)}$  at the highest junction temperature.
2. The minimum  $I_{OCSET}$  from the specification table.
3. Determine  $I_{PEAK}$  for  $I_{PEAK} > I_{OUT(MAX)} + \frac{(\Delta I)}{2}$ , where  $\Delta I$  is the output inductor ripple current.

For an equation for the ripple current see the section under component guidelines titled 'Output Inductor Selection'.

A small ceramic capacitor should be placed in parallel with  $R_{OCSET}$  to smooth the voltage across  $R_{OCSET}$  in the presence of switching noise on the input voltage.

### ***Thermal Protection (S0/S3 State)***

If the ISL6537 IC junction temperature reaches a nominal temperature of +140°C, all regulators will be disabled. The ISL6537 will not re-enable the outputs until the junction temperature drops below +110°C and either the bias voltage is toggled in order to initiate a POR or the SLP\_S5 signal is forced LOW and then back to HIGH.

### ***Shoot-Through Protection***

A shoot-through condition occurs when both the upper and lower MOSFETs are turned on simultaneously, effectively shorting the input voltage to ground. To protect from a shoot-through condition, the ISL6537 incorporates specialized circuitry on the  $V_{DDQ}$  regulator which insures that complementary MOSFETs are not ON simultaneously.

The adaptive shoot-through protection utilized by the  $V_{DDQ}$  regulator looks at the lower gate drive pin, LGATE, and the upper gate drive pin, UGATE, to determine whether a MOSFET is ON or OFF. If the voltage from UGATE or from LGATE to GND is less than 0.8V, then the respective MOSFET is defined as being OFF and the other MOSFET is allowed to turn ON. This method allows the  $V_{DDQ}$  regulator to both source and sink current.

Since the voltage of the MOSFET gates are being measured to determine the state of the MOSFET, the designer is encouraged to consider the repercussions of introducing external components between the gate drivers and their respective MOSFET gates before actually implementing such measures. Doing so may interfere with the shoot-through protection.

## ***Application Guidelines***

### ***Layout Considerations***

Layout is very important in high frequency switching converter design. With power devices switching efficiently at 250kHz, the resulting current transitions from one device to another cause voltage spikes across the interconnecting impedances and parasitic circuit elements. These voltage spikes can degrade efficiency, radiate noise into the circuit, and lead to device overvoltage stress. Careful component layout and printed circuit board design minimizes these voltage spikes.

As an example, consider the turn-off transition of the control MOSFET. Prior to turn-off, the MOSFET is carrying the full load current. During turn-off, current stops flowing in the MOSFET and is picked up by the lower MOSFET. Any parasitic inductance in the switched current path generates a large voltage spike during the switching interval. Careful component selection, tight layout of the critical components, and short, wide traces minimizes the magnitude of voltage spikes.

There are two sets of critical components in the ISL6537 switching converter. The switching components are the most

critical because they switch large amounts of energy, and therefore tend to generate large amounts of noise. Next are the small signal components which connect to sensitive nodes or supply critical bypass current and signal coupling.

A multi-layer printed circuit board is recommended. Figure 2 shows the connections of the critical components in the converter. Note that capacitors  $C_{IN}$  and  $C_{OUT}$  could each represent numerous physical capacitors. Dedicate one solid layer, usually a middle layer of the PC board, for a ground plane and make all critical component ground connections with vias to this layer. Dedicate another solid layer as a power plane and break this plane into smaller islands of common voltage levels. Keep the metal runs from the PHASE terminals to the output inductor short. The power plane should support the input power and output power nodes. Use copper filled polygons on the top and bottom circuit layers for the phase nodes. Use the remaining printed circuit layers for small signal wiring. The wiring traces from the GATE pins to the MOSFET gates should be kept short and wide enough to easily handle the 1A of drive current.

In order to dissipate heat generated by the internal  $V_{TT}$  LDO, the ground pad, pin 29, should be connected to the internal ground plane through at least four vias. This allows the heat to move away from the IC and also ties the pad to the ground plane through a low impedance path.

The switching components should be placed close to the ISL6537 first. Minimize the length of the connections between the input capacitors,  $C_{IN}$ , and the power switches by placing them nearby. Position both the ceramic and bulk input capacitors as close to the upper MOSFET drain as possible. Position the output inductor and output capacitors between the upper and lower MOSFETs and the load.

The critical small signal components include any bypass capacitors, feedback components, and compensation components. Place the PWM converter compensation components close to the FB and COMP pins. The feedback resistors should be located as close as possible to the FB pin with vias tied straight to the ground plane as required.

### Feedback Compensation - PWM Buck Converter

Figure 3 highlights the voltage-mode control loop for a synchronous-rectified buck converter. The output voltage ( $V_{OUT}$ ) is regulated to the Reference voltage level. The error amplifier output ( $V_{E/A}$ ) is compared with the oscillator (OSC) triangular wave to provide a pulse-width modulated (PWM) wave with an amplitude of  $V_{IN}$  at the PHASE node. The PWM wave is smoothed by the output filter ( $L_O$  and  $C_O$ ).

The modulator transfer function is the small-signal transfer function of  $V_{OUT}/V_{E/A}$ . This function is dominated by a DC Gain and the output filter ( $L_O$  and  $C_O$ ), with a double pole break frequency at  $F_{LC}$  and a zero at  $F_{ESR}$ . The DC Gain of the modulator is simply the input voltage ( $V_{IN}$ ) divided by the peak-to-peak oscillator voltage  $\Delta V_{OSC}$ .

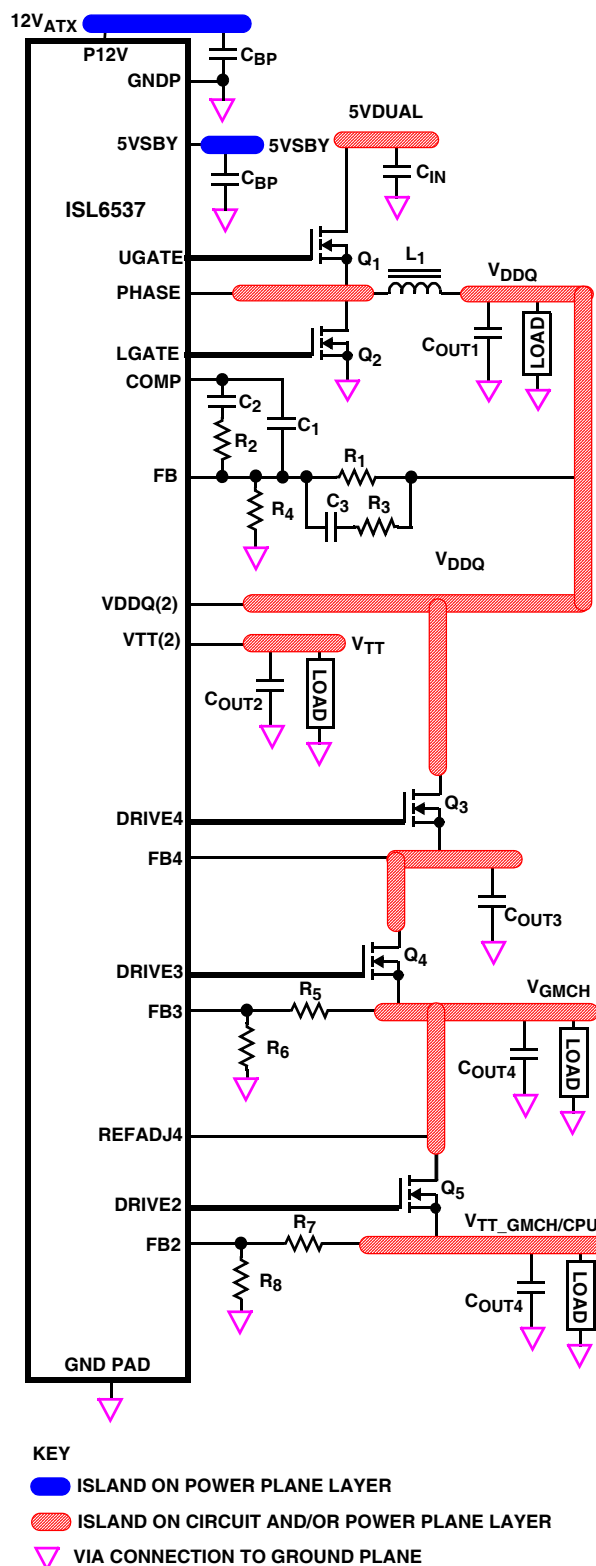

FIGURE 2. PRINTED CIRCUIT BOARD POWER PLANES AND ISLANDS

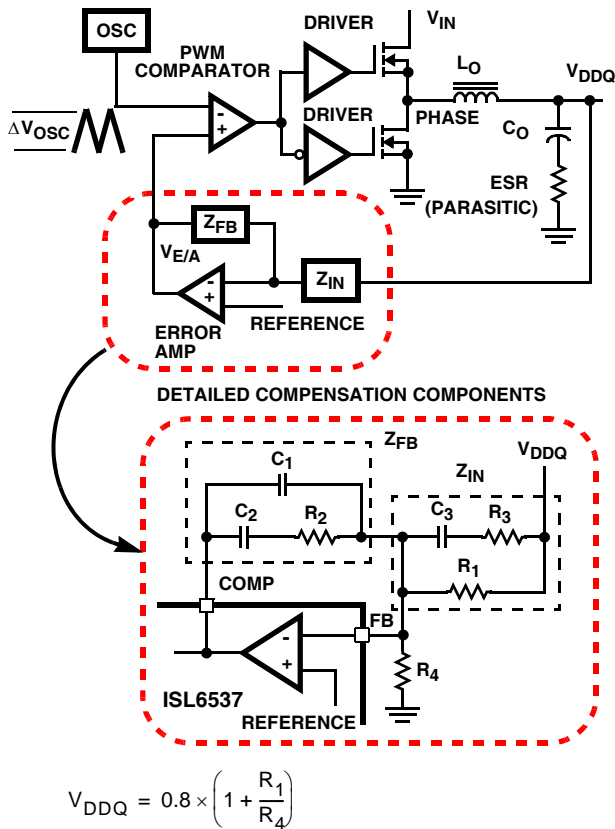

FIGURE 3. VOLTAGE-MODE BUCK CONVERTER COMPENSATION DESIGN AND OUTPUT VOLTAGE SELECTION

### Modulator Break Frequency Equations

$$F_{LC} = \frac{1}{2\pi \times \sqrt{L_O \times C_O}} \quad F_{ESR} = \frac{1}{2\pi \times ESR \times C_O} \quad (\text{EQ. 4})$$

The compensation network consists of the error amplifier (internal to the ISL6537) and the impedance networks  $Z_{IN}$  and  $Z_{FB}$ . The goal of the compensation network is to provide a closed loop transfer function with the highest 0dB crossing frequency ( $f_{0dB}$ ) and adequate phase margin. Phase margin is the difference between the closed loop phase at  $f_{0dB}$  and 180 degrees. The equations below relate the compensation network's poles, zeros and gain to the components ( $R_1$ ,  $R_2$ ,  $R_3$ ,  $C_1$ ,  $C_2$ , and  $C_3$ ) in Figure 5. Use these guidelines for locating the poles and zeros of the compensation network:

1. Pick Gain ( $R_2/R_1$ ) for desired converter bandwidth.
2. Place 1<sup>ST</sup> Zero Below Filter's Double Pole ( $\sim 75\% F_{LC}$ ).
3. Place 2<sup>ND</sup> Zero at Filter's Double Pole.
4. Place 1<sup>ST</sup> Pole at the ESR Zero.
5. Place 2<sup>ND</sup> Pole at Half the Switching Frequency.
6. Check Gain against Error Amplifier's Open-Loop Gain.
7. Estimate Phase Margin - Repeat if Necessary.

### Compensation Break Frequency Equations

$$F_{Z1} = \frac{1}{2\pi \times R_2 \times C_1} \quad F_{P1} = \frac{1}{2\pi \times R_2 \times \left( \frac{C_1 \times C_2}{C_1 + C_2} \right)}$$

$$F_{Z2} = \frac{1}{2\pi \times (R_1 + R_3) \times C_3} \quad F_{P2} = \frac{1}{2\pi \times R_3 \times C_3} \quad (\text{EQ. 5})$$

Figure 4 shows an asymptotic plot of the DC/DC converter's gain vs. frequency. The actual Modulator Gain has a high gain peak due to the high Q factor of the output filter and is not shown in Figure 4. Using the above guidelines should give a Compensation Gain similar to the curve plotted. The open loop error amplifier gain bounds the compensation gain. Check the compensation gain at  $F_{P2}$  with the capabilities of the error amplifier. The Closed Loop Gain is constructed on the graph of Figure 4 by adding the Modulator Gain (in dB) to the Compensation Gain (in dB). This is equivalent to multiplying the modulator transfer function to the compensation transfer function and plotting the gain.

The compensation gain uses external impedance networks  $Z_{FB}$  and  $Z_{IN}$  to provide a stable, high bandwidth (BW) overall loop. A stable control loop has a gain crossing with -20dB/decade slope and a phase margin greater than 45 degrees. Include worst case component variations when determining phase margin.

FIGURE 4. ASYMPTOTIC BODE PLOT OF CONVERTER GAIN

### Output Voltage Selection

The output voltage of the all the external voltage regulators converter can be programmed to any level between their individual input voltage and the internal reference, 0.8V. An external resistor divider is used to scale the output voltage relative to the reference voltage and feed it back to the inverting input of the error amplifier, refer to the Typical Application on page 3.

The output voltage programming resistor will depend on the value chosen for the feedback resistor and the desired output voltage of the particular regulator.

$$R4 = \frac{R1 \times 0.8V}{V_{DDQ} - 0.8V}$$

$$R6 = \frac{R5 \times 0.8V}{V_{GMCH} - 0.8V} \quad (\text{EQ. 6})$$

$$R8 = \frac{R7 \times 0.8V}{V_{TT\_GMCH/CPU} - 0.8V}$$

If the output voltage desired is 0.8V, simply route the output voltage back to the respective FB pin through the feedback resistor and do not populate the output voltage programming resistor.

The output voltage for the internal  $V_{TT\_DDR}$  linear regulator is set internal to the ISL6537 to track the  $V_{DDQ}$  voltage by 50%. There is no need for external programming resistors.

## Component Selection Guidelines

### Output Capacitor Selection - PWM Buck Converter

An output capacitor is required to filter the inductor current and supply the load transient current. The filtering requirements are a function of the switching frequency and the ripple current. The load transient requirements are a function of the slew rate (di/dt) and the magnitude of the transient load current. These requirements are generally met with a mix of capacitors and careful layout.

DDR memory systems are capable of producing transient load rates above 1A/ns. High frequency capacitors initially supply the transient and slow the current load rate seen by the bulk capacitors. The bulk filter capacitor values are generally determined by the ESR (Effective Series Resistance) and voltage rating requirements rather than actual capacitance requirements.

High frequency decoupling capacitors should be placed as close to the power pins of the load as physically possible. Be careful not to add inductance in the circuit board wiring that could cancel the usefulness of these low inductance components. Consult with the manufacturer of the load on specific decoupling requirements.

Use only specialized low-ESR capacitors intended for switching-regulator applications for the bulk capacitors. The bulk capacitor's ESR will determine the output ripple voltage and the initial voltage drop after a high slew-rate transient. An aluminum electrolytic capacitor's ESR value is related to the case size with lower ESR available in larger case sizes. However, the Equivalent Series Inductance (ESL) of these capacitors increases with case size and can reduce the usefulness of the capacitor to high slew-rate transient loading. Unfortunately, ESL is not a specified parameter. Work with your capacitor supplier and measure the capacitor's

impedance with frequency to select a suitable component. In most cases, multiple electrolytic capacitors of small case size perform better than a single large case capacitor.

### Output Capacitor Selection - LDO Regulators

The output capacitors used in LDO regulators are used to provide dynamic load current. The amount of capacitance and type of capacitor should be chosen with this criteria in mind.

### Output Inductor Selection

The output inductor is selected to meet the output voltage ripple requirements and minimize the converter's response time to the load transient. The inductor value determines the converter's ripple current and the ripple voltage is a function of the ripple current. The ripple voltage and current are approximated by the following equations:

$$\Delta I = \frac{V_{IN} - V_{OUT}}{F_s \times L} \times \frac{V_{OUT}}{V_{IN}} \quad \Delta V_{OUT} = \Delta I \times ESR \quad (\text{EQ. 7})$$

Increasing the value of inductance reduces the ripple current and voltage. However, the large inductance values reduce the converter's response time to a load transient.

One of the parameters limiting the converter's response to a load transient is the time required to change the inductor current. Given a sufficiently fast control loop design, the ISL6537 will provide either 0% or 100% duty cycle in response to a load transient. The response time is the time required to slew the inductor current from an initial current value to the transient current level. During this interval the difference between the inductor current and the transient current level must be supplied by the output capacitor. Minimizing the response time can minimize the output capacitance required.

The response time to a transient is different for the application of load and the removal of load. The following equations give the approximate response time interval for application and removal of a transient load:

$$t_{RISE} = \frac{L \times I_{TRAN}}{V_{IN} - V_{OUT}} \quad t_{FALL} = \frac{L \times I_{TRAN}}{V_{OUT}} \quad (\text{EQ. 8})$$

where:  $I_{TRAN}$  is the transient load current step,  $t_{RISE}$  is the response time to the application of load, and  $t_{FALL}$  is the response time to the removal of load. The worst case response time can be either at the application or removal of load. Be sure to check both of these equations at the minimum and maximum output levels for the worst case response time.

### Input Capacitor Selection - PWM Buck Converter

Use a mix of input bypass capacitors to control the voltage overshoot across the MOSFETs. Use small ceramic capacitors for high frequency decoupling and bulk capacitors to supply the current needed each time the upper MOSFET

turns on. Place the small ceramic capacitors physically close to the MOSFETs and between the drain of upper MOSFET and the source of lower MOSFET.

The important parameters for the bulk input capacitance are the voltage rating and the RMS current rating. For reliable operation, select bulk capacitors with voltage and current ratings above the maximum input voltage and largest RMS current required by the circuit. Their voltage rating should be at least 1.25 times greater than the maximum input voltage, while a voltage rating of 1.5 times is a conservative guideline. For most cases, the RMS current rating requirement for the input capacitor of a buck regulator is approximately 1/2 the DC load current.

The maximum RMS current required by the regulator may be closely approximated through the following equation:

$$I_{RMS\_MAX} = \sqrt{\frac{V_{OUT}}{V_{IN}} \times \left( I_{OUT\_MAX}^2 + \frac{1}{12} \times \left( \frac{V_{IN} - V_{OUT}}{L \times f_s} \times \frac{V_{OUT}}{V_{IN}} \right)^2 \right)} \quad (EQ. 9)$$

For a through hole design, several electrolytic capacitors may be needed. For surface mount designs, solid tantalum capacitors can be used, but caution must be exercised with regard to the capacitor surge current rating. These capacitors must be capable of handling the surge-current at power-up. Some capacitor series available from reputable manufacturers are surge current tested.

### MOSFET Selection - PWM Buck Converter

The ISL6537 requires 2 N-Channel power MOSFETs for switching power and a third MOSFET to block backfeed from  $V_{DDQ}$  to the Input in S3 Mode. These should be selected based upon  $r_{DS(ON)}$ , gate supply requirements, and thermal management requirements.

In high-current applications, the MOSFET power dissipation, package selection and heatsink are the dominant design factors. The power dissipation includes two loss components; conduction loss and switching loss. The conduction losses are the largest component of power dissipation for both the upper and the lower MOSFETs. These losses are distributed between the two MOSFETs according to duty factor. The switching losses seen when sourcing current will be different from the switching losses seen when sinking current. When sourcing current, the upper MOSFET realizes most of the switching losses. The lower switch realizes most of the switching losses when the

converter is sinking current (see the equations below). These equations assume linear voltage-current transitions and do not adequately model power loss due the reverse-recovery of the upper and lower MOSFET's body diode. The gate-charge losses are dissipated in part by the ISL6537 and do not significantly heat the MOSFETs. However, large gate-charge increases the switching interval,  $t_{SW}$  which increases the MOSFET switching losses. Ensure that both MOSFETs are within their maximum junction temperature at high ambient temperature by calculating the temperature rise according to package thermal-resistance specifications. A separate heatsink may be necessary depending upon MOSFET power, package type, ambient temperature and air flow.

### Approximate Losses while Sourcing current

$$P_{UPPER} = I_O^2 \times r_{DS(ON)} \times D + \frac{1}{2} \cdot I_O \times V_{IN} \times t_{SW} \times f_s$$

$$P_{LOWER} = I_O^2 \times r_{DS(ON)} \times (1 - D)$$

### Approximate Losses while Sinking current

$$P_{UPPER} = I_O^2 \times r_{DS(ON)} \times D \quad (EQ. 10)$$

$$P_{LOWER} = I_O^2 \times r_{DS(ON)} \times (1 - D) + \frac{1}{2} \cdot I_O \times V_{IN} \times t_{SW} \times f_s$$

Where: D is the duty cycle =  $V_{OUT} / V_{IN}$ ,  
 $t_{SW}$  is the combined switch ON and OFF time, and  
 $f_s$  is the switching frequency.

### MOSFET Selection - LDO

The main criteria for selection of the linear regulator pass transistor is package selection for efficient removal of heat. Select a package and heatsink that maintains the junction temperature below the rating with a maximum expected ambient temperature.

The power dissipated in the linear regulator is:

$$P_{LINEAR} \cong I_O \times (V_{IN} - V_{OUT}) \quad (EQ. 11)$$

where  $I_O$  is the maximum output current and  $V_{OUT}$  is the nominal output voltage of the linear regulator.
