

ADV780x 2D-Only Operation

Abstract

The ADV780x supports an SDR or a DDR SDRAM external memory interface. It uses this external memory for 3D combing, 3D digital noise reduction, and for time base correction.

For applications that do not require these advanced features, the ADV780x can operate without the external SDRAM. This document outlines the hardware and software changes required to operate the ADV780x without 3D functionality.

Hardware Changes

It is necessary to implement the following hardware changes in order to operate the ADV780x without the SDRAM memory connected:

- SDRAM VDD supplies should be connected to DVDDIO
- SDRAM VREF should be connected to DGND
- DQ and DQS lines should be connected to ground through a 4k7 resistor
- All other memory pins can be left unconnected

For more information, refer to Figure 1.

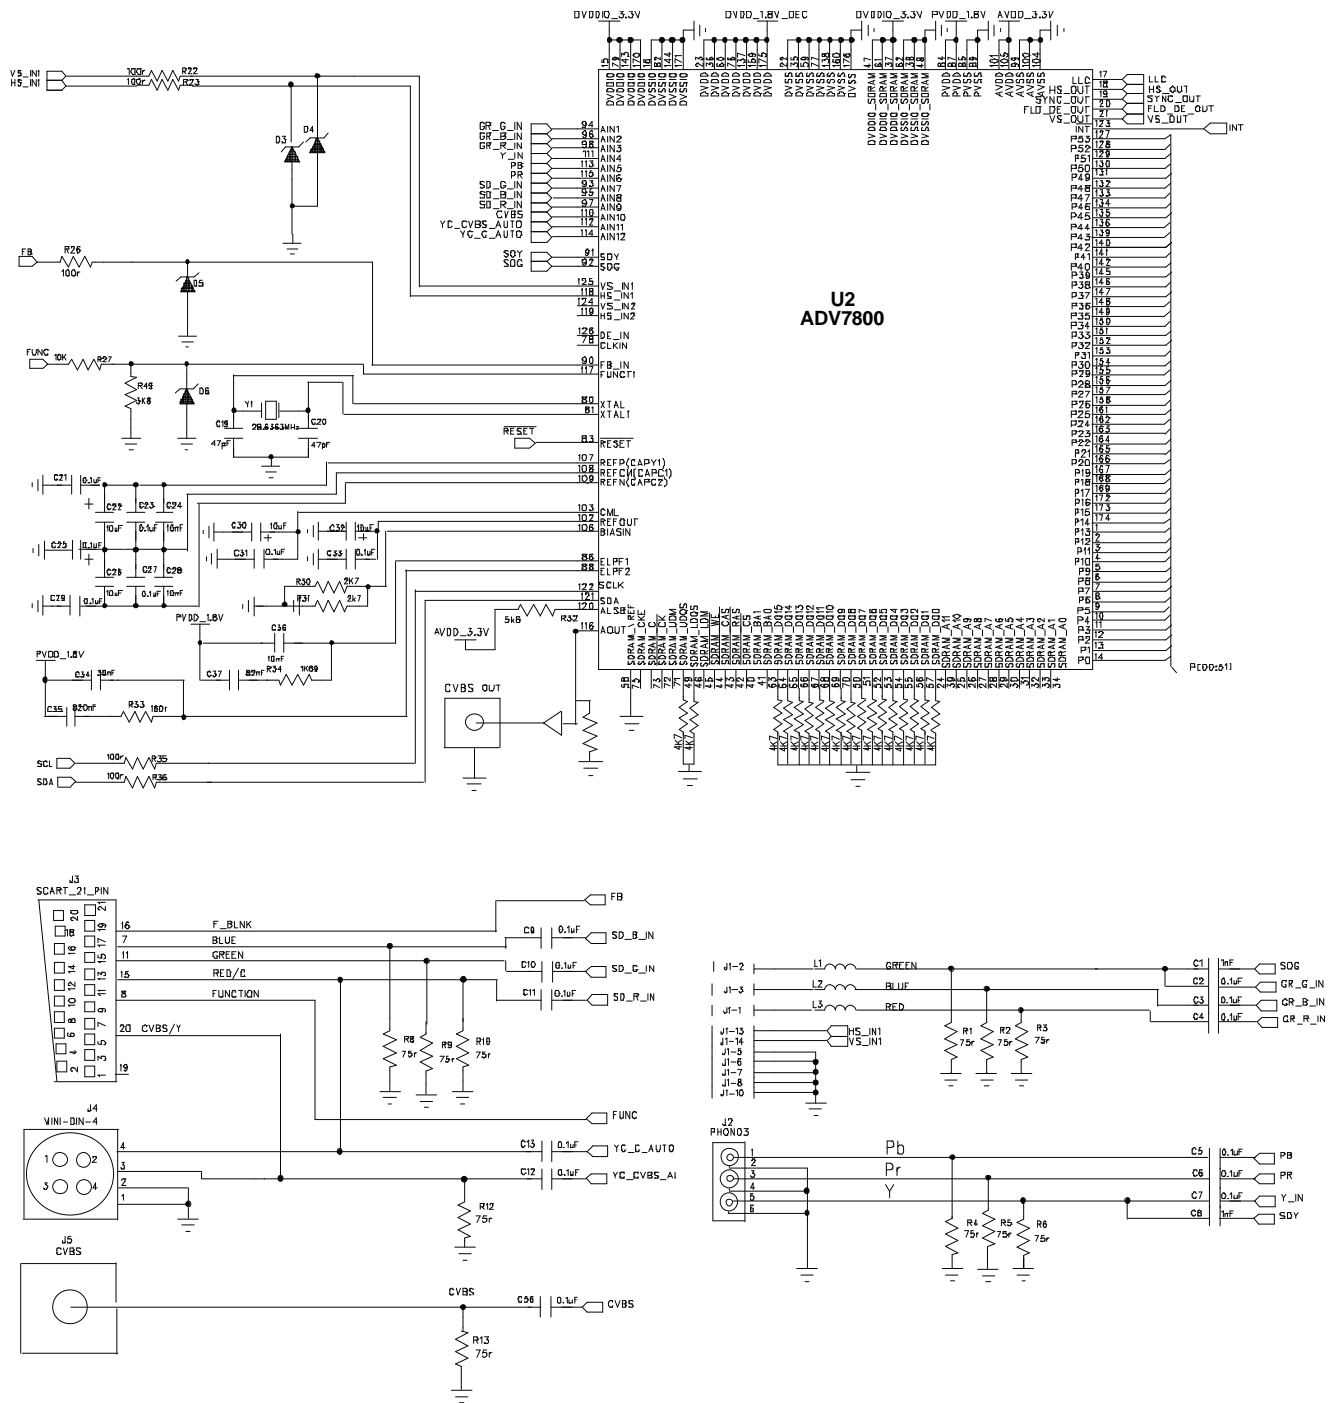

Figure 1: Typical Connection Diagram (without external memory)

Software Changes

A number of software changes are required for correct operation with external memory disconnected:

- ADV7800 memory pins should be tristated.
 - IO Map Register 0x29 bit [4] should be set to 1.
-
- Disable 3D comb, 3D DNR, Frame TBC.
 - SDP Map Register 0x12 bit [0], [1], and [2] respectively should be set to 0.
- Disable clock to external memory. This is recommended to give lower power consumption.
 - IO Map Register 0x39 bit [6] should be set to 1.
- Disable Y_2D_PK_EN. This control enables 2D detail enhancements for 2D combed areas of image in 3D comb modes. This should only be used in a 3D application.
 - SDP Map Register 0x0E bit [4] should be set to 0.
