Rev. 1 - 9 March 2010
Product data sheet

## 1. General description

The TDA8026 is a cost-effective, analog interface for addressing multiple smart card slots in a Point Of Sales (POS) terminal. It can address up to two main cards (synchronous or asynchronous smart cards supported) and up to four Security Access Modules (SAMs). Its packaging supports the latest payment terminal security requirements.

## 2. Features and benefits

- $I^{2} \mathrm{C}$-bus controlled IC card interface in a TFBGA64 package

■ Supply voltage between 2.7 V and 5.5 V

- Dedicated microcontroller interface supply voltage ( $\mathrm{V}_{\mathrm{DD}(\text { (NTF) })}$ )
- Shutdown mode ensures very low power consumption when the TDA8026 is inactive
- Programmable power reduction modes triggered when the card slots are inactive
- $\mathrm{V}_{\mathrm{CC}(\mathrm{n})}$ generation via DC-to-DC converter: two card slots can be fully loaded, the three others in reduced consumption mode
- Two clock input pins: CLKIN1 for card slot 1 and CLKIN2 for card slots 2 to 5
- Two transparent I/O lines on microcontroller side, one for card slot 1 and the other for card slots 2 to 5
- Five protected, half-duplex, bidirectional, buffered I/O lines with current limitation at $\pm 15 \mathrm{~mA}$ and a maximum frequency 1 MHz
- Two $\mathrm{I}^{2} \mathrm{C}$-bus controlled auxiliary I/O lines
- $\mathrm{V}_{\mathrm{CC}(\mathrm{n})}$ regulation on all card slots at $\mathrm{I}_{\mathrm{CC}} \leq 55 \mathrm{~mA}$ :
- $5 \mathrm{~V}, 3 \mathrm{~V}$ or $1.8 \mathrm{~V} \pm 5 \%$
- Current spikes of 40 nAs up to 20 MHz for 5 V cards with controlled rise and fall times
- Current limitation of approximately 100 mA
- Thermal protection and short-circuit protection on all card contacts
- Automatic activation and deactivation sequences initiated by the software or hardware in the event of a short-circuit, card take-off or voltage drop-out for $\mathrm{V}_{\mathrm{DD} \text { (INTF) }}, \mathrm{V}_{\mathrm{DD}}$ or $\mathrm{V}_{\text {UP }}$
■ Enhanced ElectroStatic Discharge (ESD) protection on the card-side up to 6 kV
- 20 MHz clock input
- Card clock generation up to 20 MHz and dividable by $1,2,4$ or 5 with synchronous frequency changes:
- Stop, HIGH or LOW
- Clock frequency between 1 MHz and 2.2 MHz in card low-power mode
- Current limitation on pin CLK $_{(n)}$
- $\mathrm{RST}_{(\mathrm{n})}$ signal lines with current limitation at 20 mA , controlled by an embedded programmable clock pulse counter on asynchronous cards or by a register on synchronous cards
- ISO 7816-3 and EMV 4.2 payment systems compatibility
- $\mathrm{V}_{\mathrm{DD}(\text { INTF) }}$ supply voltage supervisor ensures correct communication between microcontroller and circuit; threshold internally fixed or set using an external resistor bridge
- $\mathrm{V}_{\mathrm{DD}}$ supply voltage supervisor for spike suppression during power-on and emergency deactivation at power-off; threshold internally fixed
- Card presence input with a 17.8 ms (typical) built-in debouncing system on card slots 1 and 2
- One interrupt signal (IRQN)

## 3. Applications

- Point Of Sale terminals
- Multiple SAM contact readers

## 4. Quick reference data

Table 1. Quick reference data
$V_{D D}=V_{D D(I N T F)}=3.3 \mathrm{~V} ; f_{c l k(\text { ext })}=10 \mathrm{MHz}$; GND $=0 \mathrm{~V}$; inductor $=10 \mu \mathrm{H}$; decoupling capacitors on pins $V_{D D}$ and $V_{U P}=10 \mu F$; $T_{\text {amb }}=25^{\circ} \mathrm{C}$ unless otherwise specified.

| Symbol | Parameter | Conditions | Min | Typ | Max | Unit |

## 8. Functional description

Remark: Throughout this document ISO 7816-3 and EMV standard terminology conventions have been adhered to and it is assumed that the reader is familiar with these.

### 8.1 Power supplies

The TDA8026 supply pins are $\mathrm{V}_{\mathrm{DD}}, \mathrm{V}_{\mathrm{DD} \text { (INTF) }}$ and GND1 to GND10.

- $V_{D D}$ must be between 2.7 V and 5.5 V
- $\mathrm{V}_{\mathrm{DD} \text { (INTF) }}$ must be between 1.6 V and 3.6 V

The $\mathrm{V}_{\mathrm{DD}}, \mathrm{V}_{\mathrm{DD}(\mathrm{INTF})}$ supply voltages can be applied to the device at any time, in any sequence. All interface signals to the system controller are referenced to the $\mathrm{V}_{\mathrm{DD} \text { (INTF) }}$ supply voltage which can be lower or higher than $\mathrm{V}_{\mathrm{DD}}$. The integrated DC-to-DC converter generates the card supply voltage $\left(\mathrm{V}_{\mathrm{CC}(\mathrm{n})}\right)$ of either $5 \mathrm{~V}, 3 \mathrm{~V}$ or $1.8 \mathrm{~V}( \pm 5 \%)$. In addition, the internal voltage regulator delivers $\mathrm{V}_{\mathrm{DD} \text { (INTREGD) }} 3.3 \mathrm{~V}$ supply voltage.

Fig 3. TDA8026 Power diagram

### 8.2 Power modes

Three power modes are available for the TDA8026. These are:

- Standby mode
- Active mode with a clock-stop sub-mode
- Shutdown mode

### 8.2.1 Standby mode

In Standby mode, both the supply voltages $\mathrm{V}_{\mathrm{DD}}$ and $\mathrm{V}_{\mathrm{DD} \text { (INTF) }}$ are applied within the specification limits as described in Table 40 on page 39. In addition, the DC-to-DC converter is not running and the card slots are not activated.

### 8.2.2 Active mode

In active mode, both the $\mathrm{V}_{\mathrm{DD}}$ and $\mathrm{V}_{\mathrm{DD} \text { (INTF) }}$ supply voltages are applied to the device within the specification limits as described in Table 40 on page 39. A minimum of one card slot is activated. All card slots can be activated at once and communication performed with up to two cards slots.

The DC-to-DC converter has been developed to handle a 116 mA (typical) DC load. This allows two active card slots to communicate with a load of 55 mA while the three remaining card slots are in clock-stop mode (see Section 8.2.3 for information about this mode) with a 2 mA load.

The DC-to-DC converter overload protection is triggered when a higher current load than specified in Table 40 on page 39 is supplied to the DC-to-DC converter (see Section 8.11 for further information).

### 8.2.3 Clock-stop mode

Clock-stop mode is a low-power mode which is triggered when a card is activated without any communication. In this mode, a supply voltage with a low frequency clock is applied to cards that do not support the clock-stop feature.

### 8.2.4 Shutdown mode

Shutdown mode is the very low power consumption mode, typically $25 \mu \mathrm{~A}$. The TDA8026 enters this mode when the SDWNN pin is driven LOW. Only presence monitoring on card slot 1 remains enabled. When card insertion or removal is detected on card slot 1 , an interrupt signal (IRQN) is sent to the microcontroller.

In shutdown mode, it is assumed that the $\mathrm{V}_{\mathrm{DD}(\text { (ITF) }}$ and $\mathrm{V}_{\mathrm{DD}}$ supply voltages are stable and the SDWNN pin is active LOW.

### 8.2.4.1 Entering shutdown mode

Shutdown mode is activated when the SDWNN pin is driven LOW. On entering this mode:

1. All card slots are automatically deactivated
2. The power consumption is reduced on completion of the deactivation sequence.

This causes the following:

- Digital module moves in to reset mode. However, card presence monitoring on slot 1 continues to operate normally
- All card slots are disabled and all card pins are forced to 0 V. Again, card presence monitoring on slot 1 continues to operate normally
- Thermal protection is disabled
- The DC-to-DC converter is bypassed
- All interface signal pull-up resistors are disconnected from their supply rail (except the pull-up resistor on the SDWNN pin)
- I/OUC1 and I/OUC2 are set to high-impedance.

Fig 4. The enter shutdown sequence

### 8.2.4.2 Exiting shutdown mode

The TDA8026 performs the following steps when exiting shutdown mode:

1. Card insertion on card slot 1 is signalled by the IRQN pin signal being driven LOW.
2. Using the IRQN pin signal, the microcontroller detects the card insertion and drives the SDWNN pin HIGH to wake-up the TDA8026
3. When the SDWNN pin is HIGH, the IRQN pin is set to HIGH and the analog module is powered-up. A full power-up sequence is executed by the TDA8026
4. When the TDA8026 is ready, the IRQN pin is set to LOW
5. The microcontroller detects the device interrupt using the IRQN pin and services it which resets pin IRQN to HIGH

Fig 5. The exit shutdown sequence

### 8.3 Voltage supervisors

### 8.3.1 Block diagram

Fig 6. The voltage supervisor circuit

### 8.3.2 Description

The voltage supervisor can be used to perform Power-On Resets (POR) and supply drop detection during a card session. The supervisors control the internal regulated supply voltage ( $\mathrm{V}_{\mathrm{DD} \text { (INTREGD) }}$ ) and the microcontroller interface supply voltage ( $\mathrm{V}_{\mathrm{DD} \text { (INTF) }}$ ) to ensure problem-free operation of the TDA8026. This block controls:

- $\mathrm{V}_{\mathrm{DD}}$ using the internal voltage regulator's output ( $\mathrm{V}_{\mathrm{DD} \text { (INTREGD) }}$ )
- the microcontroller interface supply voltage $\left(\mathrm{V}_{\mathrm{DD}(\mathrm{INTF})}\right)$ using the voltage on the PORADJ pin (VPoradJ)

When an alarm occurs, the internal digital controller resets the TDA8026.

Fig 7. $\quad V_{D D}$ voltage supervisor

Fig 8. $\quad \mathrm{V}_{\mathrm{DD} \text { (INTF) }}$ voltage supervisor
Remark: Refer to the Application note AN10724 for further information.

### 8.3.3 $\mathrm{V}_{\mathrm{DD} \text { (INTREGD) }}$ Voltage supervisor without external divider on PORADJ pin

 An alarm signal is triggered and the analog controller resets the TDA8026 when:- $\mathrm{V}_{\mathrm{DD} \text { (INTREGD) }}$ is less than $\mathrm{V}_{\text {th }}$ on pin $\mathrm{V}_{\mathrm{DD} \text { (INTREGD) }}$
- Pin PORADJ monitoring $\mathrm{V}_{\mathrm{DD}(\text { INTF) }}$ is less than $\mathrm{V}_{\text {th }}$

The alarm is reset and the TDA8026 leaves reset mode 8 ms after $\mathrm{V}_{\mathrm{DD}}$ and $\mathrm{V}_{\text {PORADJ }}$ are above their respective $\mathrm{V}_{\text {th }}+\mathrm{V}_{\text {hys }}$.
$\mathrm{V}_{\text {th }}$ on $\mathrm{V}_{\mathrm{DD}(\text { INTF) }}$ is set as shown in Equation 1:
$V_{t h}=V_{b g}\left(1+\frac{R 2}{R 1}\right)$

Thus $\mathrm{V}_{\mathrm{bg}}=1.21 \mathrm{~V}$ (see Figure 6).
In reset mode, the TDA8026 is inactive and does not respond to any external command lines.

## $8.4 \mathrm{I}^{2} \mathrm{C}$-bus description

Remark: Refer to the $I^{2} C$-bus specification for more information.
The $\mathrm{I}^{2} \mathrm{C}$-bus interface in the TDA8026 is an $\mathrm{I}^{2} \mathrm{C}$-bus slave operating either Standard mode ( 100 kHz ) or Fast mode ( 400 kHz ). In addition, it integrates shift register functions, shift timing generation and slave address recognition.

### 8.4.1 $\quad \mathrm{I}^{2} \mathrm{C}$-bus protocol

The $I^{2} \mathrm{C}$-bus protocol is based on bidirectional, 2-line communication between ICs or modules. The serial bus consists of two bidirectional lines: one for data signals (SDA) and one for clock signals (SCL). Both the SDA and SCL lines must be connected to the $\mathrm{V}_{\mathrm{DD} \text { (INTF) }}$ supply voltage using a pull-up resistor (refer to the $I^{2} C$-bus specification for more details).

The $\mathrm{I}^{2} \mathrm{C}$-bus protocol is defined as follows:

- Data transfer can only be initialized when the $\mathrm{I}^{2} \mathrm{C}$-bus is not busy.
- During data transfer, the data line must remain stable when the clock line is HIGH. Changes in the data line while the clock line is HIGH are interpreted as control signals.

### 8.4.2 Bus conditions

The following bus conditions are defined.
Bus not busy - Both data and clock lines remain HIGH.
Start data transfer - The START condition is generated when the state of the data line changes from HIGH to LOW while the clock line is HIGH.

Stop data transfer - The STOP condition is generated when the state of the data line changes from LOW to HIGH while the clock line is HIGH.
Data valid - The data line state represents valid data, after a START condition with the data line stable for the duration of the clock signal HIGH period. There is one clock pulse per bit of data.

### 8.4.3 Data transfer

Each data transfer is triggered by a START condition and finished by a STOP condition (see Figure 13 for timing information).

Data transfers can be performed in Standard mode at 100 kHz or Fast mode at 400 kHz . Data transfer is performed on a byte for byte basis in both read or write modes. The information is transmitted in bytes and each receiver acknowledges with a $9^{\text {th }}$ bit (acknowledge).

Each byte is followed by an acknowledge bit and the transmitter must release the SDA line during the acknowledge bit. The master generates an extra acknowledge related clock pulse. The addressed slave receiver must generate an acknowledge bit after receiving each byte. The master-receiver must generate an acknowledge bit after receiving each byte clocked out of the slave transmitter.

The acknowledging device must pull-down the SDA line during the acknowledge clock pulse to ensure the SDA line is stable LOW during the acknowledge related clock pulse HIGH period.

In addition, the set-up and hold times must be taken into account. The master-receiver must signal the end of the last data byte to the slave transmitter by not sending an acknowledge bit on the last byte that has been clocked out of the slave. The transmitter must ensure the data line is HIGH to enable the master to generate the STOP condition.

### 8.4.4 Device addressing

Three device addresses are needed to control the TDA8026.

- One high address: The high address enables selection of a bank page (Bank 0 or Bank 1) based on a configuration byte. A bank page relates to a card slot or general registers. See Table 7 for detailed information.
- Two low addresses: The microcontroller uses two low addresses to read and write into the selected bank page (see Table 6 on page 14 to Table 39 on page 37 for detailed information).

The addresses for the device are shown in Table 5 and Table 6.
Table 5. Base addressing

| Bit 7 | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 1 | 0 | 0 | 1 | A0 | 0 | R/W |

Bit 1 is the address bit which selects Register0 or Register1. Bit 0 defines either Read or Write mode.

- When bit 0 is set to logic 1 , read mode is selected
- When bit 0 is set to logic 0 , write mode is selected

Table 6. Write mode addresses

| A0 Pin | Bank 0 base register <br> address (Hex) | Bank 1 Register0 address <br> (Hex) | Bank 1 Register1 <br> address (Hex) |
| :--- | :--- | :--- | :--- |
| 0 | 48 h | 40 h | 42 h |
| 1 | 4 Ch | 44 h | 46 h |

Bank 1 page selection is performed when the configuration byte (CSb[7:0]) is written to the high address representing bank 0 based on the A 0 pin value.

Using pin A0, two TDA8026s can be used in parallel based on the selection made to the address selection pin $A 0$. Pin $A 0$ is externally hardwired to the pins $V_{D D(I N T F)}$ or $G N D$. The voltage on the A 0 pin sets the bit 2 address bit

### 8.5 Banks and registers

The device registers enable the microcontroller to control the TDA8026. These registers are defined as banks:

- Bank 0 register is a read/write register which enables selection of the required card slot number and access to the corresponding registers Bank 1 registers. In addition, Bank 0 is used to write information about the interrupt status and the product version. The registers in bank $0(\mathrm{CSb}[7: 0]=1 \mathrm{~h}$ to 5 h$)$ are similar to the registers of the TDA8023.
- Bank 1 provides access to the corresponding card slot registers. Bank 1 is composed of several pages which in turn contain registers related to each individual card slot or general registers. Typically, pages can contain two general registers or five card slot related registers.

Remark: The registers are organized in bank pages in order to keep compatibility with the TDA8023.

Bank 1 page selection is performed when the configuration byte (CSb[7:0]) is written to the high $\mathrm{I}^{2} \mathrm{C}$-bus address representing bank 0 based on the A 0 pin.

Table 7. Register overview

| Page number/ register Subaddress (Hex)[1] | Register name | R/W | Bit definition |  |  |  |  |  |  |  | Reset value (Binary) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Bit 7 | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 |  |
| Bank 0: Card slot selection, product version and interrupt registers (see Table 8 and Table 9) |  |  |  |  |  |  |  |  |  |  |  |

[4] REG[1:0] $=01$ depending on the setting for Bank1 CSb[7:0].
[5] REG[1:0] = 10 depending on the setting for Bank1 CSb[7:0].
[6] REG[1:0] = 11 depending on the setting for Bank1 CSb[7:0].

### 8.5.2 Bank 0 register description

The device registers enable the microcontroller to control the TDA8026. The registers are organized in bank pages to ensure compatibility with the TDA8023.

Bank 0 write register enables selection of the card slot number and access to the corresponding registers in bank 1. The card slot registers in bank 1 are accessed using the configuration byte (CSb[7:0]). The range 01h to 05h is used to select the specific card slot starting at card slot $1(01 \mathrm{~h})$ and ending with card slot $5(05 \mathrm{~h})$ in a similar way to the TDA8023 registers.
8.5.2.1 Bank 0 register (address: 48h) bit allocation

| Access |  |  |  |  |  |  |  |

### 8.5.2.2 Bank 0 bit description

Table 9. Bank 0 bit description

| Bit | Symbol | Value | Description |
| :--- | :--- | :--- | :--- |
| 7 to 0 | CSb[7:0] |  | Bank 1 page selection: |
|  |  | 00 h | selects product version and interrupts status register page |
|  |  | 01 h | selects card slot 1 page |
|  |  | 02 h | selects card slot 2 page |
|  |  | 03 h | selects card slot 3 page |
|  |  | 04 h | selects card slot 4 page |
|  |  | 05 h | selects card slot 5 page |
|  |  | 06 h | selects the clock frequency and I/O lines slew rate settings page |

### 8.5.3 Bank 1 card slots 1 and 2 register descriptions

8.5.3.1 Bank $1 \mathrm{CSb}[7: 0]$ Register0 (address 40 h ) card slot 1 and card slot 2 bit allocation

Table 10. Bank 1 CSb[7:0] Register0 (address 40h) card slot 1 and card slot 2 bit allocation

| Bit | $\mathbf{7}$ | $\mathbf{6}$ | $\mathbf{5}$ | $\mathbf{4}$ | $\mathbf{3}$ | $\mathbf{2}$ | $\mathbf{1}$ | $\mathbf{0}$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Card slot 1 | (address 01h) | and Card slot 2 (address 02h) |  |  |  |  |  |  |
| Symbol | ACTIVE | EARLY | MUTE | PROT | SUPL | CLKSW | PRESL | PRES |
| Access | [1]R | $R$ | $R$ | $R$ | $R$ | $R$ | $R$ | $R$ |
| Symbol | VCC1V8 | I/OEN | REG[1:0] | PDWN | 5V/3VN | WARM | START |  |
| Access | [1]W | W | W | W | W | W | W | W |

[1] See Table 11 for the read mode bits and Table 12 for the write mode bits.
When at least one of the PRESL, SUPL, PROT, MUTE and EARLY bits is set to logic 1, IRQN pin is driven LOW until the status byte has been read. After power-on, the SUPL bit is set to logic 1 until the status byte has been read and the IRQN pin is LOW until the voltage supervisor is deactivated.
8.5.3.2 Bank 1 Register0 card slot 1 (address 01h) and card slot 2 (address 02h) read mode bit descriptions

Table 11. Bank 1 Register0 card slot 1 (address 01h) and card slot 2 (address 02h) read mode bit descriptions

| Bit | Symbol | Value | Description |
| :---: | :---: | :---: | :---: |
| 7 | ACTIVE | 1 | set to logic 1: the card is active |
|  |  | 0 | set to logic 0 : the card is inactive |
| 6 | EARLY | 1 | set to logic 1: during ATR, when the card answers too early |
|  |  | 0 | set to logic 0 : after reading the byte |
| 5 | MUTE | 1 | set to logic 1: during ATR, when the card does not answer according to the ISO 7816 time period |
|  |  | 0 | set to logic 0 : after reading the byte |
| 4 | PROT | 1 | set to logic 1: during a card session when an overload or overheating occurs |
|  |  | 0 | set to logic 0 : after reading the byte |
| 3 | SUPL | 1 | set to logic 1: when the supervisor signals a fault |
|  |  | 0 | set to logic 0 : after reading the byte |
| 2 | CLKSW | 1 | set to logic 1: when the card slot is in Power-down mode and the clock has switched to $f_{\text {osc (int) }} / 2$ <br> Remark: ( $\mathrm{f}_{\text {osc(int) }}$ is the internal oscillator frequency) |
|  |  | 0 | set to logic 0 : when exiting Power-down mode and when the clock is switched back to the $\mathrm{f}_{\mathrm{clk}(\text { ext })}$ frequency ${ }^{[1]}$ |
| 1 | PRESL | 1 | set to logic 1: the card has been inserted or extracted |
|  |  | 0 | set to logic 0 : after reading the byte |
| 0 | PRES | 1 | set to logic 1: the card is present |
|  |  | 0 | set to logic 0 : the card is not present or has been removed |

[^0]8.5.3.3 Bank 1 Register0 card slot 1 (address 01h) and card slot 2 (address 02h) write mode bit descriptions

Table 12. Bank 1 Register0 card slot 1 (address 01 h ) and card slot 2 (address 02h) write mode bit descriptions

| Bit | Symbol | Value | Description |
| :---: | :---: | :---: | :---: |
| 7 | VCC1V8[1] |  | used together with the $5 \mathrm{~V} / 3 \mathrm{VN}$ bit |
|  |  | 1 | set to logic $1: \mathrm{V}_{\mathrm{CC}(\mathrm{n})}=1.8 \mathrm{~V}$; ignores the $5 \mathrm{~V} / 3 \mathrm{VN}$ bit logic state |
|  |  | 0 | set to logic 0 : $\mathrm{V}_{\mathrm{CC}(\mathrm{n})}$ is set using the $5 \mathrm{~V} / 3 \mathrm{VN}$ bit |
| 6 | 1/OEN[2] | 1 | set to logic 1: pins I/OUCn are switched to pins I/ $\mathrm{O}_{(\mathrm{n})}$ |
|  |  | 0 | set to logic 0 : pins $\mathrm{I} / \mathrm{OUCn}$ and $\mathrm{I} / \mathrm{O}_{(\mathrm{n})}$ are high-impedance with internal pull-up resistor |
| 5 to 4 | REG[1:0] | - | See Table 13 "Bank 1 CSb[7:0] Register0 (address 42h) card slots 1 and card slots 2 bit allocation" on page 21 for detailed information |
| 3 | PWDN[3] | 1 | set to logic 1 to apply the CLKPD[1:0] bit clock settings to pin $\mathrm{CLK}_{(\text {n })}$ for the selected card slot |
|  |  | 0 | set to logic 0 to apply the CLKDIV[1:0] bits clock options to pin $\mathrm{CLK}_{(\text {n })}$ for the selected card slot |
| 2 | $5 \mathrm{~V} / 3 \mathrm{VN}$ [1] | 1 | used together with VCC1V8 bit. set to logic 1 and the $\mathrm{VCC1V8}$ bit is logic $0: \mathrm{V}_{\mathrm{CC}(\mathrm{n})}=5 \mathrm{~V}$ |
|  |  | 0 | set to logic 0 and the VCC1V8 bit is logic $0: \mathrm{V}_{\mathrm{CC}(\mathrm{n})}=3 \mathrm{~V}$ |
| 1 | WARM | 1 | set to logic 1: a warm reset procedure is started |
|  |  | 0 | set to logic 0 : by hardware when a START bit is detected or when MUTE bit is set to logic 1 |
| 0 | START | 1 | set to logic 1: starts the activation sequence and cold reset procedure (only if the SUPL and PROT bits are logic 0 and the PRES bit is logic 1) |
|  |  | 0 | set to logic 0 : starts the deactivation sequence |

[1] This bit cannot be written when the START bit is logic 1.
[2] It is a mandatory condition for card slots 2 to 5 that only one card slot I/O line is enabled at a time. When switching from one slot to another, the enabled I/O must be disabled before the I/O line for the required card slot is enabled.
Remark: If both pins I/OUC1 and I/OUC2 are connected at the same time, this mandatory condition also applies to card slot 1.
[3] In synchronous mode, this bit cannot be written when START bit is logic 1.

| 1 | WARM | 1 | set to logic 1: a warm reset procedure is started |
|  |  | 0 | set to logic 0 : by the hardware: a START bit is detected or the MUTE bit is set to logic 1 |
| 0 | START | 1 | set to logic 1: when the SUPL and PROT bits are logic 0 and the PRES bit is logic 1 , the activation sequence and cold reset procedure are started |
|  |  | 0 | set to logic 0: deactivation sequence starts |

[1] This bit cannot be written when START bit is logic 1.
[2] It is a mandatory condition for card slots 2 to 5 that only one card slot I/O line is enabled at a time. When switching from one slot to another, the enabled I/O must be disabled before the I/O line for the required card slot is enabled.
Remark: If both pins I/OUC1 and I/OUC2 are connected at the same time, this mandatory condition also applies to card slot 1 .
[3] In synchronous mode, this bit cannot be written when START bit is logic 1.

| 7 to 0 | $\mathrm{C}[7: 0]$ | least significant byte of a programmable 16 -bit clock counter. This value <br> applies to all slots. The reset value is 74 h . See Section 8.9 on page 35 |

### 8.5.5 Selection of asynchronous or synchronous mode

When the activation sequence starts, the selected card slot on the TDA8026 uses the RSTIN bit value to configure itself for use with asynchronous or synchronous cards. If the RSTIN bit is set to logic 1 at the activation sequence start (the START bit changes from LOW to HIGH), the TDA8026 will manage asynchronous cards.

In asynchronous mode, the card slot $\mathrm{RST}_{(\mathrm{n})}$ pin is controlled by the corresponding ATR counter (see Section 8.9 on page 35).

In synchronous mode, the card slot RST $_{(n)}$ pin is controlled by the corresponding RSTIN bit. The card clock configuration is set by the PWDN bit value at the activation sequence start of the selected card slot (the START bit changed from LOW to HIGH).

- If the PDWN bit is set to logic 0 at the start of the activation, the card clock value is the CLKIN1 pin frequency for card slot 1 and the CLKIN2 pin frequency for card slots 2
to 5 . If CLKDIV[1:0] $=00$, the first four clock cycles are not transferred to CLK $_{(n)}$. When CLKDIV[1:0] $=01,10$ or 11, the first five clock cycles are not transferred to $\mathrm{CLK}_{\text {(n) }}$.
- If the PDWN bit is set to logic 1 at the start of the activation, the clock uses the CLKPD1 bit.

The card clock frequency and the stop state are configured using the CLKDIV[1:0] and CLKPD[1:0] bits. Refer to Table 32 for the configuration in asynchronous mode and Table 33 for synchronous mode.

Table 32. Asynchronous mode card clock settings

| PWDN bit | CLKDIV[1:0] bit | CLKPD[1:0] bit | Card clock (CLK) |
| :--- | :--- | :--- | :--- |
| 0 | 00 | - | $\mathrm{f}_{\mathrm{clk}(\text { ext })}$ |
| 0 | 01 | - | $\mathrm{f}_{\mathrm{clk}(\text { ext })} / 2$ |
| 0 | 10 | - | $\mathrm{f}_{\mathrm{clk}(\text { ext })} / 4$ |
| 0 | 11 | - | $\mathrm{f}_{\mathrm{clk}(\text { ext })} / 5$ |
| 1 | - | 00 | $\operatorname{logic} 0$ |
| 1 | - | 01 | $\operatorname{logic} 1$ |
| 1 | - | 10 | $f_{\text {osc(int) }} / 2$ |
| 1 | - | 11 | $\mathrm{f}_{\text {clk (ext) }} / \mathrm{x}$ (no change) |

Table 33. Synchronous mode card clock settings

| PWDN bit | CLKDIV[1:0] bit | CLKPD[1:0] bit | Card clock (CLK) |
| :--- | :--- | :--- | :--- |
| logic 1 at activation sequence start | - | x 0 | logic 0 |
| logic 1 at activation sequence start | - | x 1 | logic 1 |
| logic 0 at activation sequence start[1] | - | xx | $\mathrm{f}_{\text {clk(ext) }}$ |

[1] If CLKDIV[1:0] = 00, the first four clock cycles are not transferred to CLK $_{(n)}$. When CLKDIV[1:0] is not 00, the first five clock cycles are not transferred to $\mathrm{CLK}_{(\mathrm{n})}$.
$\mathrm{f}_{\text {clk(ext) }}$ is the clock input frequency on either pin CLKIN1 or pin CLKIN2 depending on the card slot number.

During transitions, no pulse is shorter than $45 \%$ of the smallest period and both the first/last clock pulse around the change have the correct width; making the frequency change synchronous.

When changing the card clock frequency from one $f_{\text {clk(ext }}$ frequency division to another, the modification is only active after the next rising clock edge.

Any change after switching the card clock frequency from an external $f_{\text {clk(ext) }}$ frequency division to the internal oscillator frequency ( $\mathrm{f}_{\text {osc(int) }}$ ) is not immediate. The change is indicated by the state of the CLKSW bit (see the register descriptions in Table 11 and Table 22). In addition, it is assumed that the $\mathrm{f}_{\text {clk(ext) }} / \mathrm{x}$ frequency division is less than or equal to 6.25 MHz .

### 8.5.6 General registers

8.5.6.1 Bank 1 General registers (address: 40h, 42h; CSb[7:0] = 00h, 06h) bit allocation

[1] The INTx numbers do not match the bit positions and are as follows: bit $4=\operatorname{INT5}$, bit $3=\operatorname{INT} 4$, bit $2=\operatorname{INT} 3$, bit $1=\operatorname{INT} 2$ and bit $0=\operatorname{INT} 1$
8.5.6.4 Bank 1 Slew rate register (address 40h; CSb[7:0] = 06h) read/write mode bit descriptions

Table 37. Bank 1 Slew rate register (address 40h; CSb[7:0] = 06h) read/write mode bit descriptions

| Bit | Symbol | Description |
| :--- | :--- | :--- |
| 7 to 6 | CLK_SR[3:2] | card slot 2 to 5 clock slew rate selection |
| 5 to 4 | IO_SR[3:2] | card slot 2 to 5 I/O slew rate selection |
| 3 to 2 | CLK_SR[1:0] | card slot 1 clock slew rate selection |
| 1 to 0 | IO_SR[1:0] | card slot 1 I/O slew rate selection |

Refer Section 8.10 on page 37 for more detailed information.

### 8.6 DC-to-DC converter

The DC-to-DC converter has been designed to provide an average of 5.4 V to the programmable voltage regulators ( $5 \mathrm{~V}, 3 \mathrm{~V}$ and 1.8 V ) for the card slots. It is capable of delivering a total DC current of 116 mA to the card slots.

If the total current from all card slots exceeds 170 mA , the overcurrent/overload protection deactivates the DC-to-DC converter. The addition of a $10 \mu \mathrm{H}$ external coil and Schottky diode ensures the DC-to-DC converter operates at an input voltage range between 2.7 V and 5.5 V .

When the DC-to-DC converter cannot act as a step-up converter, an overload alarm is sent to the digital module and all card slot interfaces are deactivated. This causes the IRQN line to be driven LOW and the Bank 1 Register 0 PROT bit is set to logic 1.

The DC-to-DC converter is deactivated when the TDA8026 is in shutdown mode.
The card slots can be directly supplied by the $\mathrm{V}_{\mathrm{DD}}$ supply voltage, if it is always above 5.25 V, thus removing the need to use the DC-to-DC converter. In this situation, the supply voltage can be directly applied to the $\mathrm{V}_{\mathrm{UP}}$ and LX pins as shown in Figure 9.

Fig 9. The DC-to-DC converter
When DCDC_OFF is set to $\mathrm{V}_{\mathrm{DD} \text { (INTF) }}$, the DC-to-DC converter is shutdown:

- the output power transistors are switched OFF
- the DC-to-DC converter current consumption is 0 A .

## 8.7 $\mathrm{V}_{\mathrm{cc}}$ buffer

The current on the $\mathrm{V}_{\mathrm{Cc}}$ buffer is internally limited to approximately 100 mA . When this limit is reached, the automatic deactivation sequence is performed. Each card slot has its own limitation and deactivation of one card slot does not affect the other card slots

The $\mathrm{V}_{\mathrm{CC}(\mathrm{n})}$ voltage should be decoupled with two low ESR 100 nF (minimum) capacitors. One capacitor should be placed close to the $\mathrm{V}_{\mathrm{CC}}$ pin of the device and the other close to the C1 pin of the card connector. See Figure 14 for detailed information.

### 8.8 Sequencer and clock counter

Each card slot has a dedicated sequencer and clock counter.
The sequencer ensures that the activation and deactivation sequences meet the ISO 7816 and EMV 4.2 standards, even during an emergency deactivation caused by card removal during transaction, supply drop out or a hardware problem. The sequencer is clocked with an internal oscillator ( $\mathrm{f}_{\text {osc( }(\mathrm{int})}$ ).

Card slot 1 or card slot 2 can only be activated if a card is detected as present in the slot and if an alarm is not triggered by the voltage supervisor. When both of these parameters are met, the card slots can be activated by setting the Command register START bit. The activation sequence is described in Section 8.8.2.

Card slots 3 to 5 do not have presence monitoring. The corresponding STAP pin is used for card presence detection on these slots.

The deactivation is initiated by the system controller or automatically in the case of a hardware problem or a supply drop out. The deactivation sequence is described in Section 8.8.3.

Outside a session, the card contacts are forced to low-impedance with respect to the GNDC pin.

### 8.8.1 Standby mode

Standby mode is the default state after a power-on reset. This mode ensures the power consumption remains low until a card is inserted or the microcontroller starts a card session. When there is not an ongoing card session, the internal oscillator runs at its low frequency ( $\mathrm{t}_{15}$ ).

A debouncing time of 17.8 ms is applied to card slot 1 and card slot 2 to allow for card insertion (presence) detection.

### 8.8.2 Activation sequence

When the card is inactive, pins $\mathrm{V}_{\mathrm{CC}(\mathrm{n})}, \mathrm{CLK}_{(\mathrm{n})}, \mathrm{RST}_{(\mathrm{n})}$ and $\mathrm{I} / \mathrm{O}_{(\mathrm{n})}$ are LOW which is low-impedance with respect to pin $\operatorname{GNDC}_{(\mathrm{n})}$ or pin GNDS depending of the card slot.

The sequencer is clocked by an internal oscillator. When everything is satisfactory (voltage supply, card presence, no hardware problem), the system controller can trigger the card present activation sequence by setting card slot's START bit to logic 1:

- The internal oscillator switches to its high frequency ( $\mathrm{t}_{0}$, see Figure 10 ).
- The DC-to-DC converter starts $\left(\mathrm{t}_{1}\right)$.
- $\mathrm{V}_{\mathrm{CC}(\mathrm{n})}$ starts to rise from 0 V to $1.8 \mathrm{~V}, 3 \mathrm{~V}$ or 5 V during the controlled rise time $\left(\mathrm{t}_{2}\right)$.
- The voltage on the $\mathrm{I} / \mathrm{O}_{(\mathrm{n})}$ pin rises to $\mathrm{V}_{\mathrm{CC}(\mathrm{n})}$, due to integrated $10 \mathrm{k} \Omega$ pull-ups for $V_{C C(n)}\left(\mathrm{t}_{3}\right)$.
$\operatorname{CLK}_{(n)}$ clock signal is sent to the card ( $t_{4}=t_{\text {act }}$ ) and the $\mathrm{RST}_{(n)}$ pin is enabled. The $\mathrm{RST}_{(\mathrm{n})}$ pin is managed by the ATR counter or the Register1 RSTIN bit depending on the card slot mode (asynchronous or synchronous).

The sequencer is clocked by $\frac{f_{\text {osc }(\text { int })}}{64}$ which leads to a time interval $\mathrm{T}=25 \mu$ s (typical).
Thus, $t_{1}=0, t_{2}=t_{1}+\frac{3 T}{2}, t_{3}=t_{1}+\frac{7 T}{2}$ and $t_{4}=t_{1}+4 T$.

In Figure 10 only one card slot is activated. If another card slot is active, the DC-to-DC converter remains active.

### 8.8.3 Deactivation sequence

When the session finishes, the microcontroller resets the START bit to logic 0 (Figure 11) and the following deactivation sequence is performed:

- Card reset: $\mathrm{RST}_{(\mathrm{n})}$ pin falls to $0 \mathrm{~V}\left(\mathrm{t}_{11}\right)$.
- Pin $\mathrm{CLK}_{(\mathrm{n})}$ is stopped $\left(\mathrm{t}_{12}\right)$.
- Pin I/O $\mathrm{O}_{(\mathrm{n})}$ falls to $0 \mathrm{~V}\left(\mathrm{t}_{13}\right)$.
- Pin $\mathrm{V}_{\mathrm{CC}(\mathrm{n})}$ falls to 0 V with a controlled slew rate $\left(\mathrm{t}_{14}\right)$.
- The DC-to-DC converter is stopped.
- Pins $\mathrm{CLK}_{(\mathrm{n})}, \mathrm{RST}_{(\mathrm{n})}, \mathrm{V}_{\mathrm{CC}(\mathrm{n})}$ and $\mathrm{I} / \mathrm{O}_{(\mathrm{n})}$ are driven to 0 V with a low-impedance switch attached to pin GNDS ( $\mathrm{t}_{15}$ ).
- The internal oscillator switches to its low frequency $\left(t_{15}\right)$

Thus, $t_{11}=0, t_{12}=t_{11}+\frac{T}{2}, t_{13}=t_{11}+T, t_{14}=t_{11}+\frac{3 T}{2}$ and $t_{15}=t_{11}+\frac{7 T}{2}$.

The deactivation time $\mathrm{t}_{\text {deact }}$ is the time that $\mathrm{V}_{\mathrm{CC}(\mathrm{n})}$ needs to be driven below 0.4 V , counting from the moment START bit is reset.

In Figure 11 only one card slot is active. If another card slot is active, the DC-to-DC converter is still active.

### 8.9 Answer to reset counters

Each TDA8026 card slot has its own sequencer. The sequencer controls the activation and deactivation sequences. In addition to these sequencers, there are two Answer To Reset (ATR) counters:

- ATR dedicated to card slot 1
- ATR dedicated to the other slots

The operating mode (asynchronous or synchronous) has to be selected by the microcontroller. The ATR counters are used in asynchronous mode to manage the $\mathrm{RST}_{(\mathrm{n})}$ pin and to check the card's ATR. In synchronous mode, the RST pin is controlled by the microcontroller using the RSTIN bit (see the bit description in Table 11 on page 19 and Table 22 on page 24) and the card's ATR is not checked.

The ATR counter module comprises two counters:

- EARLY answer counter: The early answer counter consists of a fixed part which counts up to 200 clock cycles. The secondary part counts up to the $D[7: 0]$ bits value of clock cycles (see the register descriptions in Table 16 on page 23 and Table 27 on page 27). The default $D$ [7:0] bits value is 170 which gives a total default count of 370 clock cycles
- MUTE counter: The mute counter counts up to $C[15: 8]$ and $C[7: 0]$ bits value for the clock cycles (see the register descriptions in Table 22 on page 24 and Table 30 on page 28). The default value of the $\mathrm{C}[15: 0]$ bits is 42100 which gives a default count of 42100 clock cycles.
Both counters can be easily quickly reprogrammed, if for example, a card does not fully meet the EMVCo/ISO7816 standards or to enable the implementation of new and enhanced standards.

When operating, the microcontroller starts to configure the selected card slot (card supply voltage) and then triggers the activation sequence using the START bit. The sequencer then performs the activation sequence. The DC-to-DC converter is started, pin $\mathrm{V}_{\mathrm{cC}(\mathrm{n})}$ is set to the previously configured card supply voltage, pin $\mathrm{I} / \mathrm{O}_{(\mathrm{n})}$ is enabled and $\mathrm{CLK}_{(\mathrm{n})}$ starts (see Section 8.8.2 on page 33 and Section 8.8.3 on page 34). Pin RST $_{(n)}$ is set to LOW.

The ATR counter dedicated to the card slot makes the following checks and takes the steps required:

- START bits from a card detected on pin $\mathrm{I} / \mathrm{O}_{(\mathrm{n})}$ during the first 200 clock cycles are ignored and the count continues.
- START bits from a card detected while pin RST $_{(n)}$ is set to LOW, with the number of clock cycles between 200 and the C[15:0] bits value (default 42100), cause the EARLY and MUTE bits to be set to logic 1. Pin RST ${ }_{(n)}$ remains LOW and the microcontroller decides if it will accept the card.
- START bits detected after the number of clock cycles is equal to the C[15:0] bits value cause pin RST $_{(n)}$ to be set to HIGH.
- START bits received from the card when the first number of clock cycles is equal to the D[7:0] bits value (default 370) and pin $\mathrm{RST}_{(\mathrm{n})}$ set to HIGH cause the EARLY bit to be set to logic 1.
- Cards not answering before 42100 clock cycles (or the C [15:0] bits value) with $\mathrm{RST}_{(\mathrm{n})}$ set to HIGH cause the MUTE bit to be set to logic 1.
- Cards answering within the correct time frame, stops the clock cycles count and the microcontroller can send commands to the card.

Figure 12 shows the timings checked by the ATR counters.

Fig 12. ATR counter timing check
When the EARLY and MUTE bits are set to logic 1, they signal an interrupt (see the bit descriptions in Table 12 on page 20, Table 22 on page 24 and Table 36 on page 31).

The sequence described in Section 8.9 relates to a cold reset. If the card is mute (has not answered), the microcontroller can start a warm reset by setting WARM bit to logic 1 (see the bit descriptions in Table 11 on page 19 and Table 22 on page 24). Then, the ATR counter set pin $\mathrm{RST}_{(\mathrm{n})}$ to LOW and performs the same timing checks (see Figure 12).

Remark: It is assumed that two card activations will not take place simultaneously on card slots 2 to 5 because only one $\mathrm{I} / \mathrm{O}_{(\mathrm{n})}$ line is available for these four slots. There is no protection on the second ATR counter against starting an activation while a count is ongoing. The first ATR counter is dedicated to the slot 1 . Consequently, it is mandatory to enable only one slot $\mathrm{I} / \mathrm{O}_{(\mathrm{n})}$ line at the same time for card slots 2 to 5 . When switching from one slot to another one, it is mandatory to first disable the slot $\mathrm{I} / \mathrm{O}_{(\mathrm{n})}$ line in use before enabling the slot $\mathrm{I} / \mathrm{O}_{(\mathrm{n})}$ line required. During this transition, no $\mathrm{I} / \mathrm{O}_{(\mathrm{n})}$ lines are enabled for card slots 2 to 5 . This allows the ATR counter to be reset between card slot switching actions. If both pins I/OUC1 and I/OUC2 are connected at the same time, this mandatory condition also applies to card slot 1.

### 8.10 Slew rate control

Slew rate control is embedded for the clock buffer and the $\mathrm{I} / \mathrm{O}_{(\mathrm{n})}$ line of each card slot. The rising and falling edge of the card clock signal can be configured using 2 bits in Register6 of bank 1. The settings based on a 30 pF load capacitance and a $\mathrm{V}_{\mathrm{CC}(\mathrm{n})}=5 \mathrm{~V}$ are shown in Table 38.

Table 38. Clock Slew rate

| CLK_SR[1] (high) | CLK_SR[2] (low) | Rise and fall time (ns) |
| :--- | :--- | :--- |
| L | L | 10 |
| L | H | 7 |
| H | L | 6 |
| H | H | 5 |

[1] The high slots are define by [1] (slot 1 ) and [3] (all other slots).
[2] The low slots are define by [0] (slot 1 ) and [2] (all other slots).
The rise and fall time is calculated from $10 \%$ to $90 \%$ and $90 \%$ to $10 \%$ (respectively) of the signal amplitude. The default setting for CLK_SR[1]/CLK_SR[3] (high) is LOW and CLK_SR[0]/CLK_SR[2] (low) is HIGH.

Only the falling edge of the card $\mathrm{I} / \mathrm{O}_{(\mathrm{n})}$ signal can be configured with the two programmable bits in Register6 of bank 1. The settings based on a 30 pF load capacitance and a $\mathrm{V}_{\mathrm{CC}(\mathrm{n})}=5 \mathrm{~V}$ are shown in Table 39 on page 37:

Table 39. I/O slew rate

| IO_SR[1] (high) | IO_SR ${ }^{[2]}$ (low) | Fall time (ns) |
| :--- | :--- | :--- |
| L | L | 67 |
| L | H | 54 |
| $H$ | L | 35 |
| H | H | 17 |
| $[1]$ | The high slots are define by [1] (slot 1) and [3] (all other slots). |  |
| $[2]$ | The low slots are define by [0] (slot 1) and [2] (all other slots). |  |

The fall time is calculated from $90 \%$ to $10 \%$ of the signal amplitude. The default setting for IO_SR[0]/IO_SR[2] (low) and IO_SR[1]/IO_SR[3] (high) is LOW (see table Table 39 on page 37).

### 8.11 Fault detection

The following fault conditions are monitored by the TDA8026.

- Overheating: All the card slots are automatically deactivated and the device is forced in to Standby mode when the detected temperature range is between $125^{\circ} \mathrm{C}$ to $209^{\circ} \mathrm{C}$. The card slot PROT bit is set to logic 1 . Above $209^{\circ} \mathrm{C}$ the device is shutdown.
- Card removal during transaction: A deactivation sequence is performed in accordance with the EMV 4.2 standard.
- DC-to-DC converter overload: All card slots are automatically deactivated and the device is placed in Standby mode when the current supplied by the DC-to-DC converter exceeds 170 mA (I $\mathrm{I}_{\mathrm{CC}}$ parameter for $\mathrm{V}_{\mathrm{CC}(\mathrm{n})}$ ). The card slot PROT bit is set to logic 1
- Card slot current limitation and deactivation: A current level drawn by a card which exceeds $120 \mathrm{~mA}\left(l_{s d}\right.$ parameter for $\mathrm{V}_{\mathrm{Cc}(\mathrm{n})}$ ) triggers the deactivation sequence on the faulty card slot. During the deactivation, the current is limited to approximately 110 mA . The card slot PROT bit is set to logic 1
- $\mathrm{V}_{\mathrm{DD}}$ or $\mathrm{V}_{\mathrm{DD}(\mathrm{INTF})}$ dropping: A voltage drop occurring on $\mathrm{V}_{\mathrm{DD}}$ or $\mathrm{V}_{\mathrm{DD}(\mathrm{NTF})}$ generates card slot deactivation followed by a device reset. The completion of this phase is validated when the SUPL bits are set to logic 1.

## 9. Limiting values

Table 40. Limiting values
In accordance with the Absolute Maximum Rating System (IEC 60134).

| Symbol | Parameter | Conditions | Min | Max | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $V_{\text {DD }}$ | supply voltage | on pin $V_{D D}$ | -0.5 | +6 | V |
| $V_{\text {DD(INTF) }}$ | interface supply voltage | on pin $\mathrm{V}_{\mathrm{DD} \text { (INTF) }}$ | -0.5 | +4.6 | V |
| $\mathrm{V}_{\mathrm{IH}}$ | HIGH-level input voltage | on all card pins | -0.5 | +6 | V |
|  |  | on all other pins | -0.5 | +4.6 | V |
| $\mathrm{V}_{0}$ | output voltage | on pin LX | [1] -0.5 | +7.2 | V |
|  |  | DC-to-DC converter output on pin VUP | [1] -0.5 | +7.2 | V |
| $P_{\text {tot }}$ | total power dissipation | $\mathrm{T}_{\text {amb }}=-25^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | - | 665 | mW |
| $\mathrm{T}_{\text {stg }}$ | storage temperature |  | -55 | +150 | ${ }^{\circ} \mathrm{C}$ |
| $V_{\text {ESD }}$ | electrostatic discharge voltage | HBM | [2] |  |  |
|  |  | on $\mathrm{I}_{(\mathrm{n})}, \mathrm{V}_{\mathrm{CC}(\mathrm{n})}, \mathrm{CLK}_{(\mathrm{n})}, \operatorname{GNDC}_{(\mathrm{n})}$, PRES, $\mathrm{RST}_{(\mathrm{n})}, \mathrm{C4}_{(1)}, \mathrm{C8}_{(1)}$ card pins | $[3]-7$ | +7 | kV |
|  |  | on all other pins | -2 | +2 | kV |
|  |  | MM |  |  |  |
|  |  | on all pins | -200 | +200 | V |
|  |  | CDM |  |  |  |
|  |  | on all pins | -500 | +500 | V |

[1] The limiting values depend on the external inductor and $\mathrm{V}_{\text {UP }}$ decoupling capacitor used.
[2] Every pin withstands the ESD test according to MIL-STD-883C class 3 for card contacts, class 2 for the remaining. Method 3015 (HBM; $1500 \Omega$; 100 pF ) defines three pulses positive and three pulses negative on each pin referenced to ground
[3] The 7 kV ESD test is performed in the typical application configuration as depicted in the Application note AN10724 with two external capacitors connected to each $\mathrm{V}_{\mathrm{CC}(n)}$ line.

## 10. Thermal characteristics

Table 41. Thermal characteristics

| Symbol | Parameter | Conditions | Typ | Unit |  |
| :--- | :--- | :--- | :--- | :--- | :--- |

## 14. Soldering of SMD packages

This text provides a very brief insight into a complex technology. A more in-depth account of soldering ICs can be found in Application Note AN10365 "Surface mount reflow soldering description".

### 14.1 Introduction to soldering

Soldering is one of the most common methods through which packages are attached to Printed Circuit Boards (PCBs), to form electrical circuits. The soldered joint provides both the mechanical and the electrical connection. There is no single soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and Surface Mount Devices (SMDs) are mixed on one printed wiring board; however, it is not suitable for fine pitch SMDs. Reflow soldering is ideal for the small pitches and high densities that come with increased miniaturization.

### 14.2 Wave and reflow soldering

Wave soldering is a joining technology in which the joints are made by solder coming from a standing wave of liquid solder. The wave soldering process is suitable for the following:

- Through-hole components
- Leaded or leadless SMDs, which are glued to the surface of the printed circuit board

Not all SMDs can be wave soldered. Packages with solder balls, and some leadless packages which have solder lands underneath the body, cannot be wave soldered. Also, leaded SMDs with leads having a pitch smaller than $\sim 0.6 \mathrm{~mm}$ cannot be wave soldered, due to an increased probability of bridging.

The reflow soldering process involves applying solder paste to a board, followed by component placement and exposure to a temperature profile. Leaded packages, packages with solder balls, and leadless packages are all reflow solderable.

Key characteristics in both wave and reflow soldering are:

- Board specifications, including the board finish, solder masks and vias
- Package footprints, including solder thieves and orientation
- The moisture sensitivity level of the packages
- Package placement
- Inspection and repair
- Lead-free soldering versus SnPb soldering

### 14.3 Wave soldering

Key characteristics in wave soldering are:

- Process issues, such as application of adhesive and flux, clinching of leads, board transport, the solder wave parameters, and the time during which components are exposed to the wave
- Solder bath specifications, including temperature and impurities

### 14.4 Reflow soldering

Key characteristics in reflow soldering are:

- Lead-free versus SnPb soldering; note that a lead-free reflow process usually leads to higher minimum peak temperatures (see Figure 16) than a SnPb process, thus reducing the process window
- Solder paste printing issues including smearing, release, and adjusting the process window for a mix of large and small components on one board
- Reflow temperature profile; this profile includes preheat, reflow (in which the board is heated to the peak temperature) and cooling down. It is imperative that the peak temperature is high enough for the solder to make reliable solder joints (a solder paste characteristic). In addition, the peak temperature must be low enough that the packages and/or boards are not damaged. The peak temperature of the package depends on package thickness and volume and is classified in accordance with Table 49 and 50

Table 49. SnPb eutectic process (from J-STD-020C)

| Package thickness $(\mathrm{mm})$ | Package reflow temperature $\left({ }^{\circ} \mathrm{C}\right)$ |  |
| :--- | :--- | :--- |
|  | Volume $\left(\mathrm{mm}^{3}\right)$ |  |
|  | $<350$ | $\geq 350$ |
|  | 235 | 220 |
|  | 220 | 220 |

Table 50. Lead-free process (from J-STD-020C)

| Package thickness (mm) | Package reflow temperature $\left({ }^{\circ} \mathbf{C}\right)$ |  |  |
| :--- | :--- | :--- | :---: |
|  | Volume $\left(\mathbf{m m}^{\mathbf{3}}\right)$ |  |  |
|  | $<\mathbf{3 5 0}$ | $\mathbf{3 5 0}$ to 2000 |  |
| $<1.6$ | 260 | 260 |  |
| $\mathbf{2 0 0 0}$ |  |  |  |
| 1.6 to 2.5 | 260 | 250 |  |
| $>2.5$ | 250 | 245 |  |

Moisture sensitivity precautions, as indicated on the packing, must be respected at all times.

Studies have shown that small packages reach higher temperatures during reflow soldering, see Figure 16.

MSL: Moisture Sensitivity Level
Fig 16. Temperature profiles for large and small components
For further information on temperature profiles, refer to Application Note AN10365 "Surface mount reflow soldering description".

## 15. Abbreviations

Table 51. Abbreviations and acronyms

| Acronym | Description |
| :--- | :--- |
| ATR | Answer To Request |
| CDM | Charged Device Model |
| ESD | ElectroStatic Discharge |
| ESR | Equivalent Series Resistance |
| HBM | Human Body Model |
| LSB | Least Significant Bit |
| MM | Machine Model |
| MSB | Most Significant Bit |
| PCB | Printed-Circuit Board |
| POR | Power-On Reset |
| POS | Point Of Sales |
| SAM | Security Access Module |

## 16. Revision history

Table 52. Revision history

| Document ID | Release date | Data sheet status | Change notice | Supersedes |
| :--- | :--- | :--- | :--- | :--- |
| TDA8026_1 | 20100309 | Product data sheet | - | 1.2 |

[1] Versions 1.0 to 1.2 have all been superseded by this version which includes changes to symbols, pin names and drawings.

## 17. Legal information

### 17.1 Data sheet status

| Document status $\underline{[1][2]}$ | Product status[3] | Definition |
| :--- | :--- | :--- |
| Objective [short] data sheet | Development | This document contains data from the objective specification for product development. |
| Preliminary [short] data sheet | Qualification | This document contains data from the preliminary specification. |
| Product [short] data sheet | Production | This document contains the product specification. |

[1] Please consult the most recently issued document before initiating or completing a design.
[2] The term 'short data sheet' is explained in section "Definitions".
[3] The product status of device(s) described in this document may have changed since this document was published and may differ in case of multiple devices. The latest product status information is available on the Internet at URL http://www.nxp.com.

### 17.2 Definitions

Draft - The document is a draft version only. The content is still under internal review and subject to formal approval, which may result in modifications or additions. NXP Semiconductors does not give any representations or warranties as to the accuracy or completeness of information included herein and shall have no liability for the consequences of use of such information.
Short data sheet - A short data sheet is an extract from a full data sheet with the same product type number(s) and title. A short data sheet is intended for quick reference only and should not be relied upon to contain detailed and full information. For detailed and full information see the relevant full data sheet, which is available on request via the local NXP Semiconductors sales office. In case of any inconsistency or conflict with the short data sheet, the full data sheet shall prevail.
Product specification - The information and data provided in a Product data sheet shall define the specification of the product as agreed between NXP Semiconductors and its customer, unless NXP Semiconductors and customer have explicitly agreed otherwise in writing. In no event however, shall an agreement be valid in which the NXP Semiconductors product is deemed to offer functions and qualities beyond those described in the Product data sheet.

### 17.3 Disclaimers

Limited warranty and liability - Information in this document is believed to be accurate and reliable. However, NXP Semiconductors does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information and shall have no liability for the consequences of use of such information.
In no event shall NXP Semiconductors be liable for any indirect, incidental, punitive, special or consequential damages (including - without limitation lost profits, lost savings, business interruption, costs related to the removal or replacement of any products or rework charges) whether or not such damages are based on tort (including negligence), warranty, breach of contract or any other legal theory.

Notwithstanding any damages that customer might incur for any reason whatsoever, NXP Semiconductors' aggregate and cumulative liability towards customer for the products described herein shall be limited in accordance with the Terms and conditions of commercial sale of NXP Semiconductors.

Right to make changes - NXP Semiconductors reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions, at any time and without notice. This document supersedes and replaces all information supplied prior to the publication hereof.
Suitability for use - NXP Semiconductors products are not designed, authorized or warranted to be suitable for use in medical, military, aircraft, space or life support equipment, nor in applications where failure or
malfunction of an NXP Semiconductors product can reasonably be expected to result in personal injury, death or severe property or environmental damage. NXP Semiconductors accepts no liability for inclusion and/or use of NXP Semiconductors products in such equipment or applications and therefore such inclusion and/or use is at the customer's own risk.
Applications - Applications that are described herein for any of these products are for illustrative purposes only. NXP Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.
NXP Semiconductors does not accept any liability related to any default, damage, costs or problem which is based on a weakness or default in the customer application/use or the application/use of customer's third party customer(s) (hereinafter both referred to as "Application"). It is customer's sole responsibility to check whether the NXP Semiconductors product is suitable and fit for the Application planned. Customer has to do all necessary testing for the Application in order to avoid a default of the Application and the product. NXP Semiconductors does not accept any liability in this respect.

Limiting values - Stress above one or more limiting values (as defined in the Absolute Maximum Ratings System of IEC 60134) will cause permanent damage to the device. Limiting values are stress ratings only and (proper) operation of the device at these or any other conditions above those given in the Recommended operating conditions section (if present) or the Characteristics sections of this document is not warranted. Constant or repeated exposure to limiting values will permanently and irreversibly affect the quality and reliability of the device.
Terms and conditions of commercial sale - NXP Semiconductors products are sold subject to the general terms and conditions of commercial sale, as published at http://www.nxp.com/profile/terms, unless otherwise agreed in a valid written individual agreement. In case an individual agreement is concluded only the terms and conditions of the respective agreement shall apply. NXP Semiconductors hereby expressly objects to applying the customer's general terms and conditions with regard to the purchase of NXP Semiconductors products by customer.

No offer to sell or license - Nothing in this document may be interpreted or construed as an offer to sell products that is open for acceptance or the grant, conveyance or implication of any license under any copyrights, patents or other industrial or intellectual property rights.
Export control - This document as well as the item(s) described herein may be subject to export control regulations. Export might require a prior authorization from national authorities.

Quick reference data - The Quick reference data is an extract of the product data given in the Limiting values and Characteristics sections of this document, and as such is not complete, exhaustive or legally binding.
Non-automotive qualified products - Unless this data sheet expressly states that this specific NXP Semiconductors product is automotive qualified, the product is not suitable for automotive use. It is neither qualified nor tested in accordance with automotive testing or application requirements. NXP Semiconductors accepts no liability for inclusion and/or use of non-automotive qualified products in automotive equipment or applications.

In the event that customer uses the product for design-in and use in automotive applications to automotive specifications and standards, customer (a) shall use the product without NXP Semiconductors' warranty of the product for such automotive applications, use and specifications, and (b) whenever customer uses the product for automotive applications beyond NXP Semiconductors' specifications such use shall be solely at customer's own risk, and (c) customer fully indemnifies NXP Semiconductors for any liability, damages or failed product claims resulting from customer design and use of the product for automotive applications beyond NXP Semiconductors' standard warranty and NXP Semiconductors' product specifications.

### 17.4 Trademarks

Notice: All referenced brands, product names, service names and trademarks are the property of their respective owners.

components . . . . . . . . . . . . . . . . . . . . . . . . . . 53

## 21. Contents

1 General description ..... 1
2 Features and benefits ..... 1
3 Applications ..... 2
4 Quick reference data ..... 2
5 Ordering information ..... 3
6 Block diagram ..... 4
7 Pinning information ..... 5
7.1 Pinning ..... 5
7.2 Pin description ..... 6
8 Functional description .....  8
8.1 Power supplies ..... 8
8.2 Power modes .....  8
8.2.1 Standby mode ..... 9
8.2.2 Active mode ..... 9
8.2.3 Clock-stop mode ..... 9
8.2.4 Shutdown mode ..... 9
8.2.4.1 Entering shutdown mode ..... 9
8.2.4.2 Exiting shutdown mode. ..... 10
8.3 Voltage supervisors ..... 11
8.3.1 Block diagram ..... 11
8.3.2 Description ..... 11
8.3.3 $\quad \mathrm{V}_{\mathrm{DD} \text { (INTREGD) }}$ voltage supervisor without external divider on PORADJ pin. ..... 12
$8.4 \quad \mathrm{I}^{2} \mathrm{C}$-bus description ..... 13
8.4.1 $\mathrm{I}^{2} \mathrm{C}$-bus protocol ..... 13
8.4.2 Bus conditions ..... 13
8.4.3 Data transfer ..... 13
8.4.4 Device addressing ..... 14
8.5 Banks and registers ..... 15
8.5.1 Register overview ..... 16
8.5.2 Bank 0 register description ..... 18
8.5.2.1 Bank 0 register (address: 48h) bit allocation ..... 18
8.5.2.2 Bank 0 bit description ..... 18
8.5.3 Bank 1 card slots 1 and 2 register descriptions ..... 18
8.5.3.1 Bank 1 CSb[7:0] Register0 (address 40h) card slot 1 and card slot 2 bit allocation ..... 18
8.5.3.2 Bank 1 Register0 card slot 1 (address 01h) and card slot 2 (address 02h) read mode bit descriptions ..... 19
8.5.3.3 Bank 1 Register0 card slot 1 (address 01h) and card slot 2 (address 02h) write mode bit descriptions ..... 20
8.5.3.4 Bank 1 CSb[7:0] Register0 (address 42h) card slots 1 and card slot 2 bit allocation ..... 21
8.5.3.5 Bank 1 Register1 (REG[1:0] = 00) card slot 1(address 01h) and card slot 2 (address 02h)read/write mode bit descriptions21
8.5.3.6 Bank 1 Register1 (REG[1:0] = 01) card slot 1 (address 01h) and card slot 2 (address 02h) bit allocation ..... 22
8.5.3.7 Bank 1 Register1 (REG[1:0] = 01) card slot 1 (address 01h) and card slot 2 (address 02h) read/write mode bit descriptions ..... 23
8.5.3.8 Bank 1 Register1 (REG[1:0] = 10) card slot 1 (address 01h) and card slot 2 (address 02h) bit allocation ..... 23
8.5.3.9 Bank 1 Register1 (REG[1:0] = 10) card slot 1 (address 01h) and card slot 2 (address 02h) read/write mode bit descriptions ..... 23
8.5.3.10 Bank 1 Register1 (REG[1:0] = 11) card slot 1 (address 01h) and card slot 2 (address 02h) bit allocation ..... 23
8.5.3.11 Bank 1 Register1 (REG[1:0] = 11) card slot 1 (address 01h) and card slot 2 (address 02h) read/write mode bit descriptions ..... 23
8.5.4 Card slots 3 to 5 register descriptions ..... 24
8.5.4.1 Bank 1 CSb[7:0] Register0 (address 40h) card slots 3 to 5 bit allocation ..... 24
8.5.4.2 Bank 1 Register0 card slot 3 (address 03h), cardslot 4 (address 04h) and card slot 5(address 05h) read mode bit descriptions . . . 24
8.5.4.3 Bank 1 Register0 card slot 3 (address 03h), cardslot 4 (address 04h) and card slot 5(address 05h) write mode bit descriptions . . . 25
8.5.4.4 Bank $1 \mathrm{CSb}[7: 0]$ Register1 (address 42 h ) cardslots 3 and 5 bit allocation26
8.5.4.5 Bank 1 Register1 (REG[1:0] = 00) card slot 3(address 03h), card slot 4 (address 04h) and cardslot 5 (address 05h) read/write mode. . . . . . . 26
8.5.4.6 Bank 1 Register1 (REG[1:0] = 01) card slot 3(address 03h), card slot 4 (address 04h) and cardslot 5 (address 05h) bit allocation27
8.5.4.7 Bank 1 Register1 (REG[1:0] = 01) card slot 3(address 03h), card slot 4 (address 04h) and cardslot 5 (address 05h) read/write mode bitdescriptions27
8.5.4.8 Bank 1 Register1 (REG[1:0] = 10) card slot 3(address 03h), card slot 4 (address 04h) and cardslot 5 (address 05h) bit allocation28
8.5.4.9 Bank 1 Register1 (REG[1:0] = 10) card slot 3(address 03h), card slot 4 (address 04h) and cardslot 5 (address 05h) read/write mode bitdescriptions28
8.5.4.10 Bank 1 Register1 (REG[1:0] = 11) card slot 3 (address 03h), card slot 4 (address 04h) and card slot 5 (address 05h) bit allocation ..... 28
8.5.4.11 Bank 1: Bank 1 Register1 (REG[1:0] = 11) cardslot 3 (address 03h), card slot 4 (address 04h) andcard slot 5 (address 05h) read/write mode bitdescriptions28
8.5.5 Selection of asynchronous or synchronous mode. ..... 28
8.5.6 General registers ..... 30
8.5.6.1 Bank 1 General registers (address: 40h, 42h; CSb[7:0] = 00h, 06h) bit allocation ..... 30
8.5.6.2 Bank 1 Product version register (address 40h; CSb[7:0] = 00h) read mode bit descriptions ..... 30
8.5.6.3 Bank 1 Interrupt register (address 42h; CSb[7:0] = 00h) read mode bit descriptions ..... 31
8.5.6.4 Bank 1 Slew rate register (address 40h; CSb[7:0] = 06h) read/write mode bit descriptions ..... 31
8.6 DC-to-DC converter ..... 32
$8.7 \quad V_{\text {CC }}$ buffer ..... 32
8.8 Sequencer and clock counter ..... 32
8.8.1 Standby mode ..... 33
8.8.2 Activation sequence ..... 33
8.8.3 Deactivation sequence ..... 34
8.9 Answer to reset counters ..... 35
8.10 Slew rate control ..... 37
8.11 Fault detection ..... 38
9 Limiting values ..... 39
10 Thermal characteristics. ..... 39
11 Characteristics ..... 40
12 Application information ..... 49
13 Package outline ..... 50
