

PIC32MX3XX/4XX Family Data Sheet

64/100-Pin General Purpose and USB 32-Bit Flash Microcontrollers

DS61143C

Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable."

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION. QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer's risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights.

QUALITY MANAGEMENT SYSTEM CERTIFIED BY DNV ISO/TS 16949:2002

Trademarks

The Microchip name and logo, the Microchip logo, Accuron, dsPIC, KEELOQ, KEELOQ logo, MPLAB, PIC, PICmicro, PICSTART, PRO MATE, rfPIC and SmartShunt are registered trademarks of Microchip Technology Incorporated in the U.S.A. and other countries.

FilterLab, Linear Active Thermistor, MXDEV, MXLAB, SEEVAL, SmartSensor and The Embedded Control Solutions Company are registered trademarks of Microchip Technology Incorporated in the U.S.A.

Microchip received ISO/TS-16949:2002 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The Company's quality system processes and procedures are for its PIC® MCUs and dsPIC® DSCs, KEELOQ® code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip's quality system for the design and manufacture of development systems is ISO 9001:2000 certified.

64/100-Pin General Purpose and USB, 32-Bit Flash Microcontrollers

High-Performance RISC CPU:

- MIPS32[®] M4K[™] 32-Bit Core with 5-Stage Pipeline
- Single-Cycle Multiply and High-Performance Divide Unit
- MIPS16e[™] Mode for Up to 40% Smaller Code Size
- User and Kernel Modes to Enable Robust Embedded System
- Two 32-Bit Core Register Files to Reduce Interrupt Latency
- Prefetch Cache Module to Speed Execution from Flash

Special Microcontroller Features:

- Operating Voltage Range of 2.3V to 3.6V
- 32-512K Flash and 8-32K Data Memory
- Additional 12 KB of Boot Flash Memory
- Pin-Compatible with most PIC24/dsPIC[®] Devices
- Multiple Power Management Modes
- Multiple Interrupt Vectors with Individually Programmable Priority
- Fail-Safe Clock Monitor Mode
- Configurable Watchdog Timer with On-Chip, Low-Power RC Oscillator for Reliable Operation
- Two Programming and Debugging Interfaces:
 - 2-wire interface with unintrusive access and real-time data exchange with application
 - 4-wire MIPS standard enhanced JTAG interface
- Unintrusive Hardware-Based Instruction Trace
- IEEE Std 1149.2 Compatible (JTAG) Boundary Scan

Analog Features:

- Up to 16-Channel 10-Bit Analog-to-Digital Converter:
 - 500 ksps conversion rate
 - Conversion available during Sleep, Idle
- Two Analog Comparators

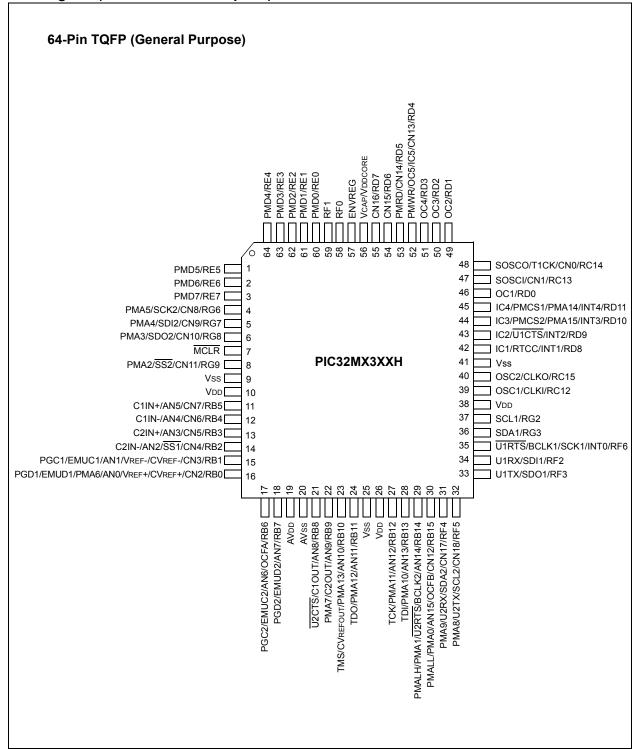

Peripheral Features:

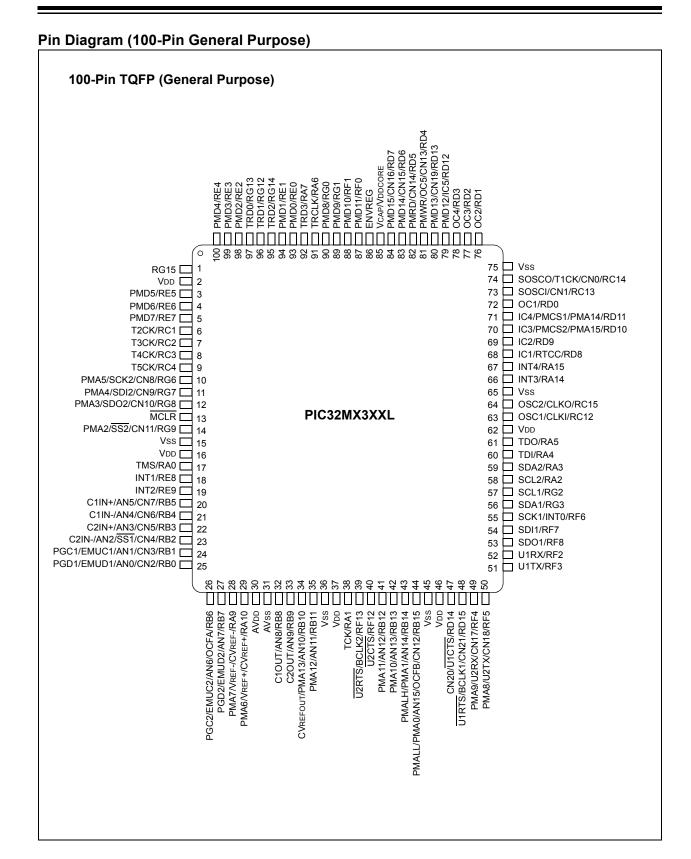

- Atomic SET, CLEAR and INVERT Operation on Select Peripheral Registers
- USB 1.1 & 2.0 compliant Full Speed Device and On The Go (OTG) controller
- Up to 4-Channel Hardware DMA Controller with Automatic Data Size Detection
- · USB has additional dedicated DMA channel
- Two I²C[™] Modules
- Two UART Modules with:
 - RS-232, RS-485 and LIN 1.2 support
- IrDA[®] with on-chip hardware encoder and decoder
- Parallel Master and Slave Port (PMP/PSP) with 8-Bit and 16-Bit Data and Up to 16 Address Lines
- Hardware Real-Time Clock/Calendar (RTCC)
- Five 16-Bit Timers/Counters (two 16-bit pairs combine to create two 32-bit timers)
- · Five Capture Inputs
- Five Compare/PWM Outputs
- · Five External Interrupt pins
- High-Current Sink/Source (18 mA/18 mA) on All I/O Pins
- Configurable Open-Drain Output on Digital I/O

TO OUR VALUED CUSTOMERS

It is our intention to provide our valued customers with the best documentation possible to ensure successful use of your Microchip products. To this end, we will continue to improve our publications to better suit your needs. Our publications will be refined and enhanced as new volumes and updates are introduced.

If you have any questions or comments regarding this publication, please contact the Marketing Communications Department via E-mail at **docerrors@microchip.com** or fax the **Reader Response Form** in the back of this data sheet to (480) 792-4150. We welcome your feedback.

Most Current Data Sheet

To obtain the most up-to-date version of this data sheet, please register at our Worldwide Web site at:

http://www.microchip.com

You can determine the version of a data sheet by examining its literature number found on the bottom outside corner of any page. The last character of the literature number is the version number, (e.g., DS30000A is version A of document DS30000).

Errata

An errata sheet, describing minor operational differences from the data sheet and recommended workarounds, may exist for current devices. As device/documentation issues become known to us, we will publish an errata sheet. The errata will specify the revision of silicon and revision of document to which it applies.

To determine if an errata sheet exists for a particular device, please check with one of the following:

· Microchip's Worldwide Web site; http://www.microchip.com

• Your local Microchip sales office (see last page)

When contacting a sales office, please specify which device, revision of silicon and data sheet (include literature number) you are using.

Customer Notification System

Register on our web site at www.microchip.com to receive the most current information on all of our products.

64/100-Pin General Purpose and USB, 32-Bit Flash Microcontrollers

1.0 DEVICE OVERVIEW

This document contains device specific information for the following devices:

- PIC32MX320F032H
- PIC32MX320F064H
- PIC32MX320F128H
- PIC32MX320F128L
- PIC32MX340F256H
- PIC32MX360F256L
- PIC32MX360F512L
- PIC32MX420F032H
- PIC32MX440F256H
- PIC32MX440F128L
- PIC32MX460F256L
- PIC32MX460F512L

This family introduces a new line of Microchip devices: a 32-bit RISC microcontroller family with a broad peripheral feature set and enhanced computational performance. The PIC32MX3XX/4XX family offers a new migration option for those high-performance applications which may be outgrowing their 16-bit platforms.

1.1 Easy Migration

The PIC32MX family of microcontrollers was designed to provide an easy migration path as the application needs change.

The consistent pinout scheme used throughout the entire family aids in migrating to the next larger device. This is true when moving between devices with the same pin count, or even jumping from 64-pin to 100-pin devices.

The PIC32MX family is pin and peripheral compatible with Microchip PIC24FJ128GA010 devices.

1.2 Core Features

1.2.1 32-BIT RISC ARCHITECTURE

Central to all PIC32MX3XX/4XX devices is the 32-bit MIPS32 M4K CPU core, offering a wide range of features, such as:

- Up to 1.56 DMIPS/MHz
- 32-bit Address and Data paths
- 32-bit Linear (program space) addressing
- (2) thirty-two element 32-bit core register files
- Single-cycle multiply and high-performance divide unit for 32-bit integer math
- 16 and 32-bit instructions, optimized for high-level languages, such as 'C'.

1.3 Power-Saving Technology

All of the devices in the PIC32MX family incorporate a range of features that can significantly reduce power consumption during operation. Key features include:

- **On-the-Fly Clock Switching:** The device clock can be changed under software control to any of the four clock sources during operation.
- Instruction-Based Power-Saving Modes: The microcontroller can suspend all operations, or selectively shut down its core while leaving its peripherals active, with a single instruction in software.

1.4 Communications

The PIC32MX incorporates a range of serial communication peripherals to handle a range of application requirements. All devices are equipped with two independent UARTs with built-in IrDA encoder/decoders. There are also two independent SPI modules, and two independent I²C modules that support both Master and Slave modes of operation.

1.5 10-Bit A/D Converter

The A/D Converter features 500 ksps maximum sample rate. This configurable module incorporates a userselectable scan list and auto-convert functions to allow acquisitions without processor intervention. Multiple A/D trigger sources are user-selectable: timer event, external pin, manual and auto-convert.

1.6 External Interface

A Parallel Master Port Parallel Slave Port enables 8/16bit parallel data communications in Master mode with up to 16 address lines; 8-bit Slave modes are also supported.

1.7 Real-Time Clock/Calendar

This module implements a full-featured clock and calendar with alarm functions in hardware, freeing up timer resources and program memory space for use of the core application.

1.8 Oscillator Options and Features

All of the devices in the PIC32MX family offer four different oscillator options, allowing users a range of choices in developing application hardware. These include:

- A Primary Oscillator (POSC) with two External Crystal modes using crystals or ceramic resonators.
- Two External Clock modes with selectable peripheral bus clock output.
- A Fast Internal Oscillator (FRC) with a nominal 8 MHz output.
- On-board postscalers and/or PLL to provide clock speeds ranging from 31 kHz to maximum specified frequency.
- A Secondary Oscillator (SOSC) designed to operate with an external 32.768 kHz crystal. This oscillator can also be used with Timer1 and the integrated RTCC.
- An Internal Low-Power RC oscillator (LPRC) having a fixed 31 kHz output, which provides a low-power option for timing-insensitive applications.

The oscillator block also provides a stable reference source for the user-controlled Fail-Safe Clock Monitor. This option constantly monitors the main clock source against a reference signal provided by the internal oscillator and enables the controller to switch to the internal oscillator, allowing for continued low-speed operation or a safe application shutdown.

2.0 PIC32MX MCU

Note: This data sheet summarizes the features of the PIC32MX3XX/4XX family of devices. It is not intended to be a comprehensive reference source. Refer to the *"PIC32MX Family Reference Manual"* (DS61132) for a detailed description of the PIC32MX mcu. Resources for the MIPS32[®] M4K[®] Processor Core are available at www.mips.com/products/cores/32-bit-cores/ mips32-m4k/#.

The MCU module is the heart of the PIC32MX3XX/4XX family processor. The MCU fetches instructions, decodes each instruction, fetches source operands, executes each instruction and writes the results of instruction execution to the proper destinations.

2.1 Features

- 5-stage pipeline
- · 32-bit Address and Data Paths
- MIPS32 Enhanced Architecture (Release 2)
 - Multiply-Accumulate and Multiply-Subtract Instructions
 - Targeted Multiply Instruction
 - Zero/One Detect Instructions
 - WAIT Instruction
 - Conditional Move Instructions (MOVN, MOVZ)
 - Vectored interrupts
 - Programmable exception vector base
 - Atomic interrupt enable/disable
 - GPR shadow registers to minimize latency for interrupt handlers
 - Bit field manipulation instructions
- MIPS16e[™] Code Compression
 - 16-bit encoding of 32-bit instructions to improve code density
 - Special PC-relative instructions for efficient loading of addresses and constants
 - SAVE & RESTORE macro instructions for setting up and tearing down stack frames within subroutines
 - Improved support for handling 8 and 16-bit data types
- Simple Fixed Mapping Translation (FMT) mechanism
- Simple Dual Bus Interface
 - Independent 32-bit address and data busses
 - Transactions can be aborted to improve interrupt latency

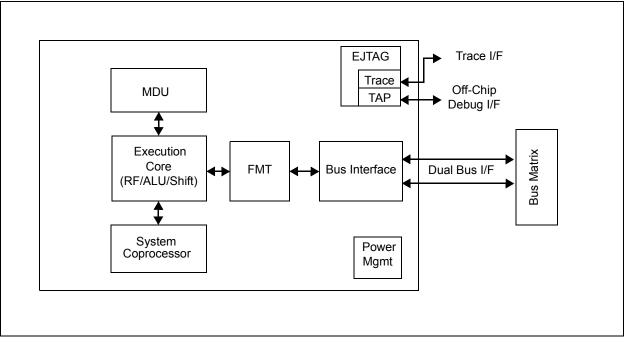

- Autonomous Multiply/Divide Unit
 - Maximum issue rate of one 32x16 multiply per clock
 - Maximum issue rate of one 32x32 multiply every other clock
 - Early-in iterative divide. Minimum 11 and maximum 34 clock latency (dividend (*rs*) sign extension-dependent)
- Power Control
 - Minimum frequency: 0 MHz
 - Low-Power mode (triggered by WAIT instruction)
 - Extensive use of local gated clocks
- EJTAG Debug and Instruction Trace
 - Support for single stepping
 - Virtual instruction and data address/value breakpoints
 - PC tracing w/ trace compression

2.2 Architecture Overview

The PIC32MX3XX/4XX family core contains several logic blocks working together in parallel, providing an efficient high performance computing engine. The blocks included with the core are as follows:

- Execution Unit
- Multiply/Divide Unit (MDU)
- System Control Coprocessor (CP0)
- Fixed Mapping Translation (FMT)
- Dual Internal Bus interfaces
- Power Management
- MIPS16e support
- Enhanced JTAG (EJTAG) Controller

FIGURE 2-1: MCU BLOCK DIAGRAM

2.2.1 EXECUTION UNIT

The PIC32MX3XX/4XX family core execution unit implements a load/store architecture with single-cycle ALU operations (logical, shift, add, subtract) and an autonomous multiply/divide unit. The core contains thirty-two 32-bit general purpose registers used for integer operations and address calculation. One additional register file shadow set (containing thirty-two registers) is added to minimize context switching overhead during interrupt/exception processing. The register file consists of two read ports and one write port and is fully bypassed to minimize operation latency in the pipeline.

The execution unit includes:

- 32-bit adder used for calculating the data address
- Address unit for calculating the next instruction address
- Logic for branch determination and branch target
 address calculation
- Load aligner
- Bypass multiplexers used to avoid stalls when executing instructions streams where data producing instructions are followed closely by consumers of their results
- Leading Zero/One detect unit for implementing the CLZ and CLO instructions
- Arithmetic Logic Unit (ALU) for performing bitwise logical operations
- Shifter and Store Aligner

2.2.2 MULTIPLY/DIVIDE UNIT (MDU)

The PIC32MX3XX/4XX family core includes a multiply/divide unit (MDU) that contains a separate pipeline for multiply and divide operations. This pipeline operates in parallel with the integer unit (IU) pipeline and does not stall when the IU pipeline stalls. This allows MDU operations to be partially masked by system stalls and/or other integer unit instructions.

The high-performance MDU consists of a 32x16 booth recoded multiplier, result/accumulation registers (HI and LO), a divide state machine, and the necessary multiplexers and control logic. The first number shown ('32' of 32x16) represents the *rs* operand. The second number ('16' of 32x16) represents the *rt* operand. The PIC32MX core only checks the value of the latter (*rt*) operand to determine how many times the operation must pass through the multiplier. The 16x16 and 32x16 operations pass through the multiplier once. A 32x32 operation passes through the multiplier twice.

The MDU supports execution of one 16x16 or 32x16 multiply operation every clock cycle; 32x32 multiply operations can be issued every other clock cycle. Appropriate interlocks are implemented to stall the issuance of back-to-back 32x32 multiply operations. The multiply operand size is automatically determined by logic built into the MDU.

Divide operations are implemented with a simple 1 bit per clock iterative algorithm. An early-in detection checks the sign extension of the dividend (*rs*) operand. If rs is 8 bits wide, 23 iterations are skipped. For a 16bit-wide rs, 15 iterations are skipped, and for a 24-bitwide rs, 7 iterations are skipped. Any attempt to issue a subsequent MDU instruction while a divide is still active causes an IU pipeline stall until the divide operation is completed.

Table 2-1 lists the repeat rate (peak issue rate of cycles until the operation can be reissued) and latency (number of cycles until a result is available) for the PIC32MX core multiply and divide instructions. The approximate latency and repeat rates are listed in terms of pipeline clocks.

TABLE 2-1:	PIC32MX3XX/4XX FAMILY CORE HIGH-PERFORMANCE INTEGER
	MULTIPLY/DIVIDE UNIT LATENCIES AND REPEAT RATES

Opcode	Operand Size (mul <i>rt</i>) (div <i>rs</i>)	Latency	Repeat Rate							
MULT/MULTU, MADD/MADDU,	16 bits	1	1							
MSUB/MSUBU	32 bits	2	2							
MUL	16 bits	2	1							
	32 bits	3	2							
DIV/DIVU	8 bits	12	11							
	16 bits	19	18							
	24 bits	26	25							
	32 bits	33	32							

The MIPS architecture defines that the result of a multiply or divide operation be placed in the HI and LO registers. Using the Move-From-HI (MFHI) and Move-From-LO (MFLO) instructions, these values can be transferred to the general purpose register file.

In addition to the HI/LO targeted operations, the MIPS32 architecture also defines a multiply instruction, MUL, which places the least significant results in the primary register file instead of the HI/LO register pair. By avoiding the explicit MFLO instruction, required when using the LO register, and by supporting multiple destination registers, the throughput of multiply-intensive operations is increased.

Two other instructions, multiply-add (MADD) and multiply-subtract (MSUB), are used to perform the multiply-accumulate and multiply-subtract operations. The MADD instruction multiplies two numbers and then adds the product to the current contents of the HI and LO registers. Similarly, the MSUB instruction multiplies two operands and then subtracts the product from the HI and LO registers. The MADD and MSUB operations are commonly used in DSP algorithms.

2.2.3 SYSTEM CONTROL COPROCESSOR (CP0)

In the MIPS architecture, CP0 is responsible for the virtual-to-physical address translation, the exception control system, the processor's diagnostics capability, the operating modes (kernel, user, and debug), and whether interrupts are enabled or disabled. Configuration information, such as presence of options like MIPS16e, is also available by accessing the CP0 registers, listed in Table 2-2.

Register Number	Register Name	Function	
0-6	Reserved	Reserved in the PIC32MX3XX/4XX family core	
7	HWREna	Enables access via the RDHWR instruction to selected hardware registers	
8	BadVAddr ⁽¹⁾	Reports the address for the most recent address-related exception	
9	Count ⁽¹⁾	Processor cycle count	
10	Reserved	Reserved in the PIC32MX3XX/4XX family core	
11	Compare ⁽¹⁾	Timer interrupt control	
12	Status ⁽¹⁾	Processor status and control	
12	IntCtl ⁽¹⁾	Interrupt system status and control	
12	SRSCtl ⁽¹⁾	Shadow register set status and control	
12	SRSMap ⁽¹⁾	Provides mapping from vectored interrupt to a shadow set	
13	Cause ⁽¹⁾	Cause of last general exception	
14	EPC ⁽¹⁾	Program counter at last exception	
15	PRId	Processor identification and revision	
15	EBASE	Exception vector base register	
16	Config	Configuration register	
16	Config1	Configuration register 1	
16	Config2	Configuration register 2	
16	Config3	Configuration register 3	
17-22	Reserved	Reserved in the PIC32MX3XX/4XX family core	
23	Debug ⁽²⁾	Debug control and exception status	
24	DEPC ⁽²⁾	Program counter at last debug exception	
25-29	Reserved	Reserved in the PIC32MX3XX/4XX family core	
30	ErrorEPC ⁽¹⁾	Program counter at last error	
31	DESAVE ⁽²⁾	Debug handler scratchpad register	

TABLE 2-2: COPROCESSOR 0 REGISTERS

Note 1: Registers used in exception processing.

2: Registers used during debug.

Coprocessor 0 also contains the logic for identifying and managing exceptions. Exceptions can be caused by a variety of sources, including alignment errors in data, external events, or program errors. Table 2-3 shows the exception types in order of priority.

Exception	Description
Reset	Assertion MCLR or a Power-On Reset (POR)
DSS	EJTAG Debug Single Step
DINT	EJTAG Debug Interrupt. Caused by the assertion of the external <i>EJ_DINT</i> input, or by setting the EjtagBrk bit in the ECR register
NMI	Assertion of NMI signal
Interrupt	Assertion of unmasked hardware or software interrupt signal
DIB	EJTAG debug hardware instruction break matched
AdEL	Fetch address alignment error Fetch reference to protected address
IBE	Instruction fetch bus error
DBp	EJTAG Breakpoint (execution of SDBBP instruction)
Sys	Execution of SYSCALL instruction
Вр	Execution of BREAK instruction
RI	Execution of a Reserved Instruction
CpU	Execution of a coprocessor instruction for a coprocessor that is not enabled
CEU	Execution of a CorExtend instruction when CorExtend is not enabled
Ov	Execution of an arithmetic instruction that overflowed
Tr	Execution of a trap (when trap condition is true)
DDBL / DDBS	EJTAG Data Address Break (address only) or EJTAG Data Value Break on Store (address + value)
AdEL	Load address alignment error Load reference to protected address
AdES	Store address alignment error Store to protected address
DBE	Load or store bus error
DDBL	EJTAG data hardware breakpoint matched in load data compare

TABLE 2-3: PIC32MX3XX/4XX FAMILY CORE EXCEPTION TYPES

2.2.4 INTERRUPT HANDLING

The PIC32MX3XX/4XX family core includes support for peripheral interrupts, two software interrupts, and a timer interrupt.

The PIC32MX MCU uses the MIPS External Interrupt Controller (EIC) mode, which redefines the way in which interrupts are handled to provide full support for an external interrupt controller handling prioritization and vectoring of interrupts. This presence of this mode denoted by the VEIC bit in the Config3 register. On the PIC32MX core, the VEIC bit is always set to '1' to indicate the presence of an external interrupt controller.

Note:	Although EIC mode is designated as	s
	"External", the interrupt controller is	
	on-chip.	

The interrupt controller specifies which shadow set should be used upon entry to a particular vector. The shadow registers further improve interrupt latency by avoiding the need to save context when invoking an interrupt handler.

2.2.5 GPR SHADOW REGISTERS

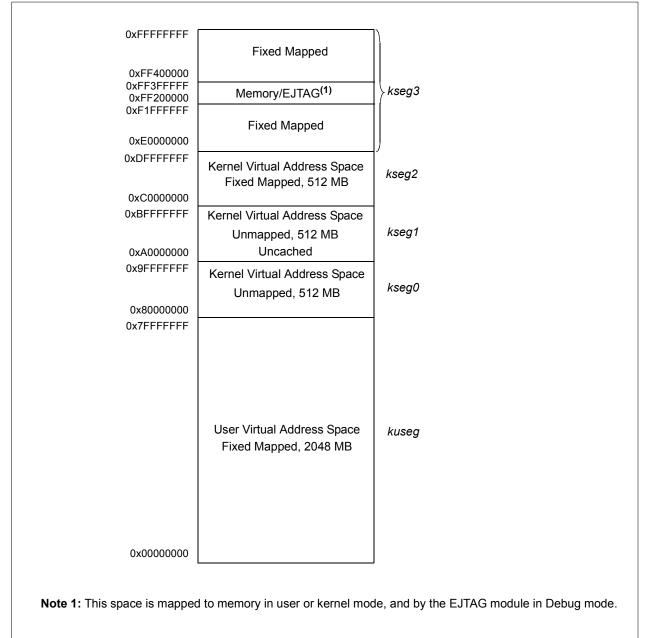

Release 2 of the MIPS32 Architecture optionally removes the need to save and restore GPRs on entry to high priority interrupts or exceptions, and to provide specified processor modes with the same capability. This is done by introducing multiple copies of the GPRs, called "shadow sets", and allowing privileged software to associate a shadow set with entry to kernel mode via an interrupt vector or exception. The normal GPRs are logically considered shadow set zero.

The PIC32MX3XX/4XX family core implements two sets of registers, the normal GPRs, and one shadow set. This is indicated by the SRSCtl_{HSS} field.

2.3 Modes of Operation

The PIC32MX3XX/4XX family core supports three modes of operation: user mode, kernel mode and debug mode. User mode is most often used for applications programs. Kernel mode is typically used for handling exceptions and operating system kernel functions, including CP0 management and I/O device accesses. An additional Debug mode is used during system bring-up and software development. Refer to the EJTAG specification for more information on debug mode.

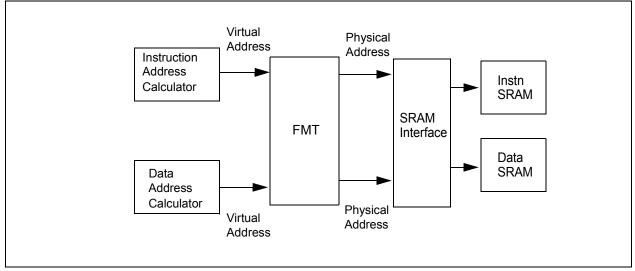

FIGURE 2-2: PIC32MX3XX/4XX FAMILY CORE VIRTUAL ADDRESS MAP

2.3.1 FIXED MAPPING TRANSLATION

The PIC32MX3XX/4XX family core provides a simple Fixed Mapping Translation (FMT) mechanism that is smaller and simpler than a full Translation Lookaside Buffer (TLB) found in other MIPS cores. Like a TLB, the FMT performs virtual-to-physical address translation and provides attributes for the different segments. Those segments that are unmapped in a TLB implementation (kseg0 and kseg1) are translated identically by the FMT. Figure 2-3 shows how the FMT is implemented in the PIC32MX core.

In general, the FMT also determines the cacheability of each segment. These attributes are controlled via bits in the Config register. Table 2-4 shows the encoding for the K23 (bits 30:28), KU (bits 27:25), and K0 (bits 2:0) fields of the Config register. The PIC32MX core passes these Config fields to the Prefetch Cache module to determine cacheability of Program Memory Flash accesses. Table 2-5 shows how the cacheability of the virtual address segments is controlled by these fields.

TABLE 2-4: CACHE COHERENCY ATTRIBUTES

Config Register Fields K23, KU, and K0	Cache Coherency Attribute
2	Uncached
3	Cacheable

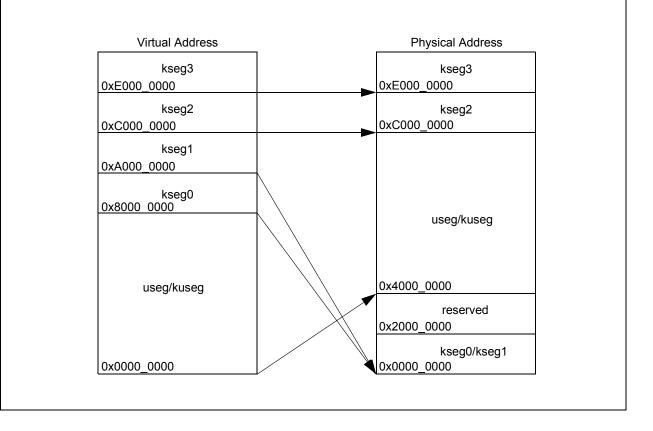

In the PIC32MX3XX/4XX family core, no translation exceptions are taken, although address errors are still possible.

TABLE 2-5: CACHEABILITY OF SEGMENTS WITH FIXED MAPPING TRANSLATION

Segment	Virtual Address Range	Cacheability
useg/kuseg	0x0000_0000-0x7FFF_FFFF	Controlled by the KU field (bits 27:25) of the Config register. See Figure 2-4 for mapping. This segment is always uncached when ERL = 1.
kseg0	0x8000_0000- 0x9FFF_FFFF	Controlled by the K0 field (bits 2:0) of the Config register. See Figure 2-4 for mapping.
kseg1	0xA000_0000-0xBFFF_FFF	Always uncacheable.
kseg2	0xC000_0000-0xDFFF_FFFF	Controlled by the K23 field (bits 30:28) of the Config register. See Figure 2-4 for mapping.
kseg3	0xE000_0000-0xFFFF_FFF	Controlled by the K23 field (bits 30:28) of the Config register. See Figure 2-4 for mapping.

The FMT performs a simple translation to map from virtual addresses to physical addresses. This mapping is shown in Figure 2-4.

FIGURE 2-4: FMT MEMORY MAP (ERL = 0) IN THE PIC32MX3XX/4XX FAMILY CORE

When ERL = 1, useg and kuseg become unmapped (virtual address is identical to the physical address) and uncached. This behavior is the same as if there was a TLB. This mapping is shown in Figure 2-5.

ha a r Q	linear 2
kseg3 0xE000_0000	kseg3 0xE000_0000
kseg2 0xC000_0000	kseg2 0xC000_0000
kseg1 0xA000_0000	reserved
kseg0 0x8000_0000	0x8000_0000
useg/kuseg	useg/kuseg
0x0000_0000	

FIGURE 2-5: PIC32MX3XX/4XX FAMILY CORE FMT MEMORY MAP (ERL = 1)

2.3.2 DUAL INTERNAL BUS INTERFACES

The SRAM interface includes dual instruction and data interfaces.

The dual interface enables independent connection to instruction and data devices. It yields the highest performance, since the pipeline can generate simultaneous I and D requests which are then serviced in parallel.

The internal buses are connected to the Bus Matrix unit, which is a switch fabric that provides this parallel operation.

2.3.3 MIPS16E EXECUTION

When the core is operating in MIPS16e mode, instruction fetches only require 16 bits of data to be returned. For improved efficiency, however, the core will fetch 32 bits of instruction data whenever the address is word-aligned. Thus for sequential MIPS16e code, fetches only occur for every other instruction, resulting in better performance and reduced system power.

2.4 Power Management

The PIC32MX3XX/4XX family core offers a number of power management features, including low-power design, active power management, and power-down modes of operation. The core is a static design that supports slowing or halting the clocks, which reduces system power consumption during idle periods.

2.4.1 INSTRUCTION-CONTROLLED POWER MANAGEMENT

The mechanism for invoking power-down mode is through execution of the WAIT instruction. For more information on power management, see **23.0** "**Power Saving**".

2.4.2 LOCAL CLOCK GATING

The majority of the power consumed by the PIC32MX3XX/4XX family core is in the clock tree and clocking registers. The PIC32MX family uses extensive use of local gated-clocks to reduce this dynamic power consumption.

2.5 EJTAG Debug Support

The PIC32MX3XX/4XX family core provides for an Enhanced JTAG (EJTAG) interface for use in the software debug of application and kernel code. In addition to standard user mode and kernel modes of operation, the PIC32MX3XX/4XX family core provides a Debug mode that is entered after a debug exception (derived from a hardware breakpoint, single-step exception, etc.) is taken and continues until a debug exception return (DERET) instruction is executed. During this time, the processor executes the debug exception handler routine.

The EJTAG interface operates through the Test Access Port (TAP), a serial communication port used for transferring test data in and out of the PIC32MX3XX/4XX family core. In addition to the standard JTAG instructions, special instructions defined in the EJTAG specification define what registers are selected and how they are used.

2.5.1 DEBUG REGISTERS

Three debug registers (DEBUG, DEPC, and DESAVE) have been added to the MIPS Coprocessor 0 (CP0) register set. The DEBUG register shows the cause of the debug exception and is used for setting up single-step operations. The DEPC, or Debug Exception Program Counter, register holds the address on which the debug exception was taken. This is used to resume program execution after the debug operation finishes. Finally, the DESAVE, or Debug Exception Save, register enables the saving of general purpose registers used during execution of the debug exception handler.

To exit debug mode, a Debug Exception Return (DERET) instruction is executed. When this instruction is executed, the system exits debug mode, allowing normal execution of application and system code to resume.

2.5.2 EJTAG HARDWARE BREAKPOINTS

There are several types of simple hardware breakpoints defined in the EJTAG specification. These stop the normal operation of the MCU and force the system into debug mode. There are two types of simple hardware breakpoints implemented in the PIC32MX3XX/4XX family core: Instruction breakpoints and Data breakpoints.

The PIC32MX3XX/4XX family core has two data and six instruction breakpoints

Instruction breaks occur on instruction fetch operations, and the break is set on the virtual address. A mask can be applied to the virtual address to set breakpoints on a range of instructions.

Data breakpoints occur on load/store transactions. Breakpoints are set on virtual address values, similar to the Instruction breakpoint. Data breakpoints can be set on a load, a store, or both. Data breakpoints can also be set based on the value of the load/store operation. Finally, masks can be applied to both the virtual address and the load/store value.

2.5.3 INSTRUCTION TRACING

The PIC32MX3XX/4XX family core includes Trace support for real-time tracing of instruction addresses. The trace information is collected in an off-chip memory, for post-capture processing by trace regeneration software.

Off-chip trace memory is accessed through a special trace probe that consists of 4 data pins plus a clock.

2.6 MCU Initialization

Software is required to initialize the following parts of the device after a reset event.

2.6.1 GENERAL PURPOSE REGISTERS

The MCU register file powers up in an unknown state with the exception of r0 which is always 0. Initializing the rest of the register file is not required for proper operation of hardware. Depending on the software environment however, several registers may need to be initialized. Some of these are:

- · SP Stack Pointer
- GP Global Pointer
- FP Frame Pointer

2.6.2 COPROCESSOR 0 STATE

Miscellaneous CP0 states need to be initialized prior to leaving the boot code. There are various exceptions which are blocked by ERL = 1 or EXL = 1 and which are not cleared by Reset. These can be cleared to avoid taking spurious exceptions when leaving the boot code.

CP0 Register	Action	
Cause	WP (Watch Pending), SW0/1 (Software Interrupts) should be cleared.	
Config	Typically, the K0, KU and K23 fields should be set to the desired Cache Coherency Algorithm (CCA) value prior to accessing the corresponding memory regions. But in the M4K core, all CCA values are treated identically, so the hardware reset value of these fields need not be modified.	
Count ⁽¹⁾	Should be set to a known value if Timer Interrupts are used.	
Compare ⁽¹⁾	Should be set to a known value if Timer Interrupts are used. The write to compare will also clear any pending Timer Interrupts (thus, Count should be set before Compare to avoid any unexpected interrupts).	
Status	Desired state of the device should be set.	
Other CP0 state	Other registers should be written before they are read. Some registers are not explicitly writable, and are only updated as a by-product of instruction execution or a taken exception. Uninitialized bits should be masked off after reading these registers.	

TABLE 2-6: CP0 INITIALIZATION

Note 1: When the Count register is equal to the Compare register, a timer interrupt is signaled. There is a mask bit in the interrupt controller to disable passing this interrupt to the MCU if desired.

2.7 I/O Pin Configuration

The MCU module has EJTAG pins that may be configured as user-available I/O pins. If EJTAG is used for debug, it is important to make sure that software does not clear DDPCON<JTAGEN>.

NOTES:

3.0 INSTRUCTION SET

The PIC32MX3XX/4XX family family instruction set complies with the MIPS32 Release 2 instruction set architecture. The PIC32MX3XX/4XX family does not support the following features:

- · CoreExtend instructions
- Coprocessor 1 instructions
- Coprocessor 2 instructions

TABLE 3-1:	PIC32MX3XX/4XX INSTRUCTION SET

TABLE 3-1: PIC32MX3XX/4XX INSTRUCTION SET (CONTINUED)

NOTES:

4.0 OSCILLATORS

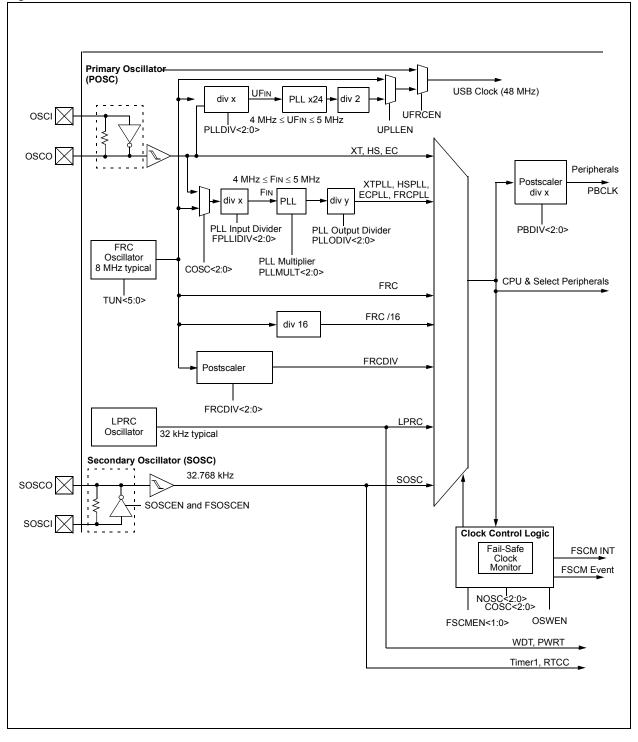

Note:	This data sheet summarizes the features of
	the PIC32MX3XX/4XX family of devices. It
	is not intended to be a comprehensive refer-
	ence source. Refer to the "PIC32MX Family
	Reference Manual" (DS61132) for a
	detailed description of this peripheral.

This section describes the PIC32MX3XX/4XX oscillator system and its operation. The PIC32MX oscillator system has the following modules and features:

- A total of four external and internal oscillator options as clock sources
- On-chip PLL with user-selectable input divider, multiplier, and output divider to boost operating frequency on select internal and external oscillator sources
- On-chip user-selectable divisor postscaler on select oscillator sources
- Software-controllable switching between various clock sources
- A Fail-Safe Clock Monitor (FSCM) that detects clock failure and permits safe application recovery or shutdown

A simplified diagram of the oscillator system is shown in Figure 4-1.

Figure 4-1: PIC32MX3XX/4XX FAMILY CLOCK DIAGRAM

4.1 Control Registers

The Oscillator module consists of the following Special Function Registers (SFRs):

OSCCON: Control Register for the Oscillator module

OSCCONCLR, OSCCONSET, OSCCONINV: Atomic Bit Manipulation Write-only Registers for OSCCON register

OSCTUN: FRC Tuning Register for the Oscillator module

OSCTUNCLR, OSCTUNSET, OSCTUNINV: Atomic Bit Manipulation Write-only Registers for OSCTUN register The Oscillator module also has the following associated bits for interrupt control:

- Interrupt Flag Status bits (IFS1<14>) for Clock Fail FSCMIF in IFS1 Interrupt register
- Interrupt Enable Control bits (IEC1<14>) for Clock Fail FSCMIE in IEC1 Interrupt register
- Interrupt Priority Control bits (FSCMIP<12:10>) for Clock Fail in IPC8 Interrupt register
- Interrupt Subpriority Control bits (FSCMIP<9:8>) for Clock Fail in IPC8 Interrupt register

The following tables provide brief summaries of Oscillator-module-related registers. Corresponding registers appear after the summaries, followed by a detailed description of each register.

4.2 Operation: Clock Generation and Clock Sources

The PIC32MX3XX/4XX device has two internal clocks: CPU clock and PB clock. They are derived from the currently selected clock source. The clock source can be chosen from the 4 available internal or external clock sources. Some of these clock sources have Phase Locked Loops (PLLs), programmable output dividers, or input divider to scale the input frequency to suit the application. The clock source can be changed on the fly by software. The oscillator control register is locked by hardware, it must be unlocked by a series of writes before software can perform a clock switch.

There are three main clocks in the PIC32MX3XX/4XX device:

- The System clock (SYSCLK) used by CPU and some peripherals
- The Peripheral Bus Clock (PBCLK) used by most peripherals
- The USB Clock (USBCLK) used by USB peripheral

The PIC32MX3XX/4XX clocks are derived from one of the following sources:

- Primary Oscillator (POSC) on the OSCI and OSCO pins
- Secondary Oscillator (SOSC) on the SOSCI and SOSCO pins
- Internal Fast RC Oscillator (FRC)

Internal Low-Power RC Oscillator (LPRC)

Each of the clock sources has unique configurable options, such as a PLL, input divider, and/or output divider, that are detailed in their respective sections.

There are up to four internal clocks depending on the specific device. The clocks are derived from the currently selected oscillator source.

Note: Clock sources for peripherals that use external clocks, such as the RTCC and Timer1, are covered in their respective sections.

4.2.1 SYSTEM CLOCK (SYSCLK) GENERATION

The SYSCLK is the primary clock used by the CPU and select peripherals such as DMA, Interrupt Controller, and Prefetch Cache. The SYSCLK is derived from one of the four clock sources: POSC, SOSC, FRC, and LPRC. Some of the clock sources have specific clock multipliers and/or divider options. No clock scaling is applied other than the user specified values. The SYS-CLK source is selected by the device configuration and can be changed by software during operation. The ability to switch clock sources during operation allows the application to reduce power consumption by reducing the clock speed. Refer to Table 4-2 for a list of SYSCLK sources.

Oscillator Mode	Oscillator Source	POSCMD<1:0>	FNOSC2: FNOSC0	Notes
Fast RC Oscillator with Postscaler (FRCDIV)	Internal	XX	111	1, 2

Fast RC Oscillator (FRC)	Internal	XX	000	1

TABLE 4-2: CLOCK SELECTION CONFIGURATION BIT VALUES (CONTINUED)

Note 1: OSCO pin function as PBCLK out or Digital I/O is determined by the OSCIOFNC Configuration bit. When the pin is not required by the Oscillator mode it may be configured for one of these options.

- **2:** Default Oscillator mode for an unprogrammed (erased) device.
- **3:** When using the PLL modes the input divider must be chosen such that resulting frequency applied to the PLL is in the range of 4 MHz to 5 MHz.
- **4:** In this mode, the PLL input divider is forced to '2' to provide a 4 MHz input to the PLL. This parameter cannot be modified and satisfies the requirements described in Note 3.

4.2.1.1 Primary Oscillator (POSC)

The POSC has six operating modes, as summarized in Table 4-3. The first three modes can each be combined with a PLL module to form the last three modes. Figures 4-2 through 4-4 show various POSC configurations. The primary oscillator is connected to the OSCI and OSCO pins of the device family. The primary oscillator can be configured for an external clock input or an external crystal or resonator.

The XT, XTPLL, HS, and HSPLL modes are External Crystal or Resonator Controller Oscillator modes. The XT and HS modes are functionally very similar. The primary difference is the gain of the internal inverter of the oscillator circuit (see Figure 4-2). The XT mode is a medium power, medium frequency mode and has medium inverter gain. HS mode is higher power and provides the highest oscillator frequencies and has the highest inverter gain. OSCO provides crystal/resonator feedback in both XT and HS Oscillator modes and hence is not available for use as a input or output in these modes. The XTPLL and HSPLL modes have a Phase Locked Loop (PLL) with user selectable input divider, multiplier, and output divider to provide a wide range of output frequencies. The oscillator circuit will consume more current when the PLL is enabled.

The External Clock modes, EC and ECPLL, allow the system clock to be derived from an external clock source. These modes configure the OSCI pin as a high-impedance input that can be driven by a CMOS driver. The external clock can be used to drive the system clock directly (EC) or the ECPLL module with prescale and postscaler can be used to change the input clock frequency (ECPLL). The External Clock modes also disables the internal feedback buffer allowing the OSCO pin to be used for other functions. In the External Clock mode the OSCO pin can be used as an additional device I/O pin (see Figure 4-4) or a PBCLK output pin (see Figure 4-3).

Note: When using the PLL modes the input divider must be chosen such that resulting frequency applied to the PLL is in the range of 4 MHz to 5 MHz.

Oscillator Mode	Description
HS	10 MHz-40 MHz crystal
XT	3.5 MHz-10 MHz resonator
EC	External clock input (0-72 MHz)
HSPLL	10 MHz-40 MHz crystal, PLL enabled
XTPLL	4 MHz-10 MHz resonator, PLL enabled
ECPLL	External clock input (5-72 MHz), PLL enabled

Note: The clock applied to the CPU after applicable prescalers, postscalers, and PLL multipliers must not exceed the maximum allowable processor frequency.

FIGURE 4-2: CRYSTAL OR CERAMIC RESONATOR OPERATION (XT, XTPLL, HS, OR HSPLL OSCILLATOR MODE)

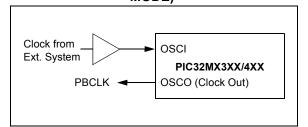

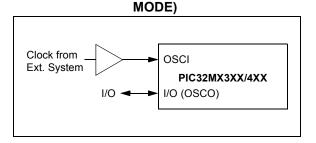

FIGURE 4-4: EXTERNAL CLOCK INPUT OPERATION WITH NO CLOCK-OUT (EC, ECPLL

4.2.1.2 Primary Oscillator (POSC) Configuration

To configure the POSC the following steps should be performed:

- Select POSC as the default oscillator in the device Configuration register, DEVCFG1, by setting FNOSC<2:0> = '010' without PLL or '011' with PLL.
- 2. Select the desired mode HS, XT, or EC, using POSCMD<1:0> in DEVCFG1.
- 3. If the PLL is to be used:
 - a)Select the appropriate Configuration bits for the PLL input divider to scale the input frequency to be between 4 MHz and 5 MHz using FPLLIDIV<2:0> in DEVCFG2.
 - b)Select the desired PLL multiplier ratio using FPLLMULT<2:0>) in DEVCFG2.
 - c)At runtime, select the desired PLL output divider using PLLODIV (OSCCON<29:27>) to provide the desired clock frequency. The default value is set by DEVCFG1.

© 2008 Microchip Technology Inc.

4.2.1.3 Oscillator Start-up Timer

In order to ensure that a crystal oscillator (or ceramic resonator) has started and stabilized, an Oscillator Start-up Timer (OST) is provided. The OST is a simple 10-bit counter that counts 1024 Tosc cycles before releasing the oscillator clock to the rest of the system. This time-out period is designated as TOST. The amplitude of the oscillator signal must reach the VIL and VIH thresholds for the oscillator pins before the OST can begin to count cycles.

The TOST interval is required every time the oscillator has to restart (i.e., on POR, BOR and wake-up from Sleep mode). The Oscillator Start-up Timer is applied to the MS and HS modes for the primary oscillator, as well as the secondary oscillator, see **Section 4.2.1.5 "Secondary Oscillator (SOSC)**".

4.2.1.4 System Clock Phase Locked Loop (PLL)

The system clock PLL provides a user configurable input divider, multiplier, and output divider which can be used with the XT, HS and EC Primary Oscillator modes and with the Internal Fast RC Oscillator (FRC) mode to create a variety of clock frequencies from a single clock source.

The Input divider, multiplier, and output divider control initial value bits are contained in the in the DEVCFG2 device Configuration register. The multiplier and output divider bits are also contained in the OSCCON register. As part of a device Reset, values from the device configuration register, DEVCFG2, are copied to the OSCCON register. This allows the user to preset the input divider to provide the appropriate input frequency to the PLL and set an initial PLL multiplier when programming the device. At runtime the multiplier, divider and output divider can be changed by software to scale the clock frequency to suit the application. The PLL input divider cannot be changed at run time. This is to prevent applying an input frequency outside the specified limits to the PLL.

To configure the PLL the following steps are required:

- 1. Calculate the PLL input divider, PLL multiplier, and PLL output divider values.
- Set the PLL input divider and the initial PLL multiplier value in the DEVCFG2 register when programming the part.
- 3. At runtime the PLL multiplier and PLL output divider can be changed to suit the application.

Combinations of PLL input divider, multiplier and output divider provide a combined multiplier of approximately 0.006 to 24 times the input frequency. For reliable operation the output of the PLL module must not exceed the maximum clock frequency of the device. The PLL input divider value should be chosen to limit the input frequency to the PLL to the range of 4 MHz to 5 MHz.

Due to the time required for the PLL to provide a stable output, a Status bit LOCK (OSCCON<5>) is provided. When the clock input to the PLL is changed, this bit is driven low ('0'). After the PLL has achieved a lock or the PLL start-up timer has expired, the bit is set. The bit will be set upon the expiration of the timer even if the PLL has not achieved a lock.

TABLE 4-4: NET MULTIPLIER OUTPUT FOR SELECTED PLL AND OUTPUT DIVIDER VALUES

4.2.1.4.1 PLL Lock Status

The LOCK bit (OSCCON<5>) is a read-only Status bit that indicates the lock status of the PLL. It is automatically set after the typical time delay for the PLL to achieve lock, also designated as TLOCK. If the PLL does not stabilize properly during start-up, LOCK may not reflect the actual status of PLL lock, nor does it detect when the PLL loses lock during normal operation.

The LOCK bit is cleared at a Power-on Reset and on clock switches when the PLL is selected as a destination clock source. It remains clear when any clock source not using the PLL is selected.

Refer to the Electrical Characteristics section in the specific device data sheet for further information on the PLL lock interval.

4.2.1.4.2 USB PLL Lock Status

The ULOCK bit (OSCCON<6>) is a read-only status bit that indicates the lock status of the USB PLL. It is automatically set after the typical time delay for the PLL to achieve lock, also designated as TLOCK. If the PLL does not stabilize properly during start-up, LOCK may not reflect the actual status of PLL lock, nor does it detect when the PLL loses lock during normal operation.

The ULOCK bit is cleared at a Power-on Reset. It remains clear when any clock source not using the PLL is selected.

Refer to the Electrical Characteristics section in the specific device data sheet for further information on the PLL lock interval.

4.2.1.4.3 Primary Oscillator Start-up from Sleep Mode

To ensure reliable wake-up from Sleep, care must be taken to properly design the primary oscillator circuit. This is because the load capacitors have both partially charged to some quiescent value and phase differential at wake-up is minimal. Thus, more time is required to achieve stable oscillation. Remember also that lowvoltage, high temperatures and the lower frequency clock modes also impose limitations on loop gain, which in turn, affects start-up.

Each of the following factors increases the start-up time:

- Low-frequency design (with a Low Gain Clock mode)
- Quiet environment (such as a battery operated device)
- Operating in a shielded box (away from the noisy RF area)
- · Low voltage
- High temperature
- Wake-up from Sleep mode

4.2.1.5 Secondary Oscillator (SOSC)

The Secondary Oscillator (SOSC) is designed specifically for low-power operation with a external 32.768 kHz crystal. The oscillator is located on the SOSCO and SOSCI device pins and serves as a secondary crystal clock source for low-power operation. It can also drive Timer1 and/or the Real-Time Clock/Calendar module for Real-Time Clock applications.

4.2.1.5.1 Enabling the SOSC Oscillator

The SOSC is hardware enabled by the FSOSCEN Configuration bit (DEVCFG1<5>). Once SOSC is enabled, software can control it by modifying SOSCEN bit (OSCCON<1>). Setting SOSCEN enables the oscillator; the SOSCO and SOSCI pins are controlled by the oscillator and cannot be used for port I/O or other functions.

Note:	An unlock sequence is required before a
	write to OSCCON can occur. Refer to
	Section 4.2.6.2 "Oscillator Switching
	Sequence" for more information.

The Secondary Oscillator requires a warm-up period before it can be used as a clock source. When the oscillator is enabled, a warm-up counter increments to 1024. When the counter expires the SOSCRDY (OSCCON<22>) is set to '1'.

4.2.1.5.2 SOSC Continuous Operation

The SOSC is always enabled when SOSCEN (OSCCON<1>) is set. Leaving the oscillator running at all times allows a fast switch to the 32 kHz system clock for lower power operation. Returning to the faster main oscillator will still require an oscillator start-up time if it is a crystal type source and/or uses the PLL.

In addition, the oscillator will need to remain running at all times for Real-Time Clock applications and may be required for Timer1.

EXAMPLE 4-1: ENABLING THE SOSC

```
SYSKEY = 0x12345678;// ensure OSCCON is lockedSYSKEY = 0xAA996655;// Write Key1 to SYSKEYSYSKEY = 0x556699AA;// Write Key2 to SYSKEYOSCCONSET = 2;// make the desired changeOSCCONSET = 2;// request clock switchSYSKEY = 0x12345678;// Write any value other than Key1 or Key2
```

4.2.1.6 Internal Fast RC Oscillator (FRC)

The FRC oscillator is a fast (8 MHz nominal), user trimmable, internal RC oscillator with user selectable input divider, PLL multiplier, and output divider.

4.2.1.6.1 FRC Postscaler Mode (FRCDIV)

Users are not limited to the nominal 8 MHz FRC output if they wish to use the fast internal oscillator as a clock source. An additional FRC mode, FRCDIV, implements a selectable output divider that allows the choice of a lower clock frequency from 7 different options, plus the direct 8 MHz output. The output divider is configured using the FRCDIV<2:0> bits (OSCCON<26:24>). Assuming a nominal 8 MHz output, available lower frequency options range from 4 MHz (divide-by-2) to 31 kHz (divide-by-256). The range of frequencies allows users the ability to save power at any time in an application by simply changing the FRCDIV bits. The FRCDIV mode is selected whenever the COSC bits (OSCCON<14:12>) are '111'.

4.2.1.6.2 FRC Oscillator with PLL Mode (FRCPLL)

The output of the FRC may also be combined with a user selectable PLL multiplier and output divider to produce a SYSCLK across a wide range of frequencies. The FRC PLL mode is selected whenever the COSC bits (OSCCON<14:12>) are '001'.

Note: In this mode, the PLL input divider is forced to '2' to provide a 4 MHz input to the PLL. This parameter cannot be modified.

The desired PLL multiplier and output divider values can be chosen to provide the desired device frequency

4.2.1.6.3 Oscillator Tune Register (OSCTUN)

The FRC Oscillator Tuning register OSCTUN allows the user to fine tune the FRC oscillator over a range of approximately $\pm 12\%$ (typical). Each bit increment or decrement changes the factory calibrated frequency of the FRC oscillator by a fixed amount.

4.2.1.7 Internal Low-Power RC Oscillator (LPRC)

The LPRC oscillator is separate from the FRC. It oscillates at a nominal frequency of 31.25 kHz. The LPRC oscillator is the clock source for the Power-up Timer (PWRT), Watchdog Timer (WDT), Fail Safe Clock Monitor (FSCM) and PLL reference circuits. It may also be used to provide a low-frequency clock source option for the device in those applications where power consumption is critical, and timing accuracy is not required.

4.2.1.7.1 Enabling the LPRC Oscillator

Since it serves the PWRT clock source, the LPRC oscillator is disabled at Power-on Reset whenever the on-board voltage regulator is enabled. After the PWRT expires, the LPRC oscillator will remain on if any one of the following is true:

- The Fail-Safe Clock Monitor is enabled.
- The WDT is enabled.
- The LPRC oscillator is selected as the system clock (COSC2:COSC0 = 100).

If none of the above is true, the LPRC will shut off after the PWRT expires.

4.2.2 PERIPHERAL BUS CLOCK (PBCLK) GENERATION

The PBCLK is derived from the System Clock (SYS-CLK) divided by PBDIV<1:0> (OSCCON<20:19>). The PBCLK Divisor bits PBDIV<1:0> allow postscalers of 1:1, 1:2, 1:4, and 1:8. Refer to the individual peripheral module section(s) for information regarding which bus a specific peripheral uses.

Notes: When the PBDIV divisor is set to a ratio of '1:1' the SYSCLK and PBCLK are equivalent in frequency. The PBCLK frequency is never greater than the processor clock frequency.

The effect of changing the PBCLK frequency on individual peripherals should be taken into account when selecting or changing the PBDIV value.

Performing back-to-back operations on PBCLK peripheral registers when the PB divisor is not set at 1:1 will cause the CPU to stall for a number of cycles. This stall occurs to prevent an operation from occurring before the pervious one has completed. The length of the stall is determined by the ratio of the CPU and PBCLK and synchronizing time between the two busses.

Changing the PBCLK frequency has no effect on the SYSCLK peripherals operation.

4.2.3 USB Clock (USBCLK) Generation

The USBCLK can be derived from 8 MHz internal FRC oscillator, 48 MHz POSC, or 96 MHz PLL from POSC. For normal operation, the USB module requires exact 48 MHz clock. When using 96 MHz PLL, the output is internally divided to obtain 48 MHz clock. The FRC clock source is used to detect USB activity and bring USB module out of SUSPEND mode. Once USB module is out of SUSPEND mode, it starts using any of two 48 MHz clock sources. The internal FRC oscillator is not used for normal USB module operation.

4.2.3.0.1 USB Clock Phase Locked Loop (UPLL)

The USB clock PLL provides a user configurable input divider which can be used with the XT, HS and EC primary oscillator modes and with the Internal Fast RC Oscillator (FRC) mode to create a variety of clock frequencies from a clock source. The actual source must be able to provide stable clock as required by the USB specifications.

The UPLL enable and Input divider bits are contained in the in the DEVCFG2 device configuration register. The input to the UPLL must be limited to 4 MHz only. Appropriate input divider must be selected to ensure that the UPLL input is 4 MHz.

To configure the UPLL the following steps are required:

- 1. Enable USB PLL by setting FUPLLEN bit in DEVCFG2 register.
- 2. Based on the source clock, calculate the UPLL input divider value such that the PLL input is 4 MHz
- 3. Set the UPLL input divider FUPLLIDIV bits in the DEVCFG2 register when programming the part.

4.2.3.0.2 USB PLL Lock Status

The ULOCK bit (OSCCON<6>) is a read-only status bit that indicates the lock status of the USB PLL. It is automatically set after the typical time delay for the PLL to achieve lock, also designated as T_{ULOCK} . If the PLL does not stabilize properly during start-up, ULOCK may not reflect the actual status of PLL lock, nor does it detect when the PLL loses lock during normal operation.

The ULOCK bit is cleared at a Power-on Reset. It remains clear when any clock source not using the PLL is selected.

Refer to the Electrical Characteristics section in the specific device data sheet for further information on the USB PLL lock interval.

4.2.3.0.3 Using Internal FRC Oscillator with USB

The internal 8 MHz FRC oscillator is available as a clock source to detect any USB activity during USB SUSPEND mode and bring the module out of the SUS-PEND mode. To enable FRC for USB usage, the UFRCEN bit (OSCCON<2>) must be set '1' before putting USB module to SUSPEND mode.

4.2.4 TWO-SPEED START-UP

Two-Speed Start-up mode can be used to reduce the device start-up latency when using all External Crystal POSC modes, including PLL. Two-Speed Start-up uses the FRC clock as the SYSCLK source until the Primary Oscillator (POSC) has stabilized. After the user selected oscillator has stabilized, the clock source will switch to POSC. This allows the CPU to begin running code, at a lower speed, while the oscillator is stabilizing. When the POSC has met the start-up criteria an automatic clock switch occurs to switch to POSC. This mode is enabled by the device Configuration bits FCKSM<1:0> (DEVCFG1<15:14>). Two-Speed Startup operates after a Power-on Reset (POR) or exit from SLEEP. Software can determine the oscillator source currently in use by reading the COSC<2:0> bits in the OSCCON register.

Note: The Watchdog Timer (WDT), if enabled, will continue to count at the same rate regardless of the SYSCLK frequency. Care must be taken to service the WDT during Two-Speed Start-up, taking into account the change in SYSCLK.

4.2.5 FAIL-SAFE CLOCK MONITOR OPERATION

The Fail-Safe Clock Monitor (FSCM) is designed to allow continued device operation if the current oscillator fails. It is intended for use with the Primary Oscillator (POSC) and automatically switches to the FRC oscillator if a POSC failure is detected. The switch to the Fast Internal RC Oscillator (FRC) oscillator allows continued device operation and the ability to retry the POSC or to execute code appropriate for a clock failure.

The FSCM mode is controlled by the FCKSM<1:0> bits in the device Configuration register, DEVCFG1. Any of the POSC modes can be used with FSCM.

When a clock failure is detected with FSCM enabled and the FSCM Interrupt Enable bit FSCMIE (IEC1<14>) set, the clock source will be switched from POSC to FRC. An Oscillator Fail interrupt will be generated, with the CF bit (OSCCON<3>) set. This interrupt has a user-settable priority FSCMIP<2:0> (IPC8<12:10>) and subpriority FSCMIS<1:0> (IPC8<9:8>). The clock source will remain FRC until a device Reset or a clock switch is performed. Failure to enable the FSCM interrupt will not inhibit the actual clock switch.

The FSCM module takes the following actions when switching to the FRC oscillator:

- 1. The COSC bits (OSCCON<14:12>) are loaded with '000'.
- The CF OSCCON<3> bit is set to indicate the clock failure
- 3. The OSWEN control bit (OSCCON<0>) is cleared to cancel any pending clock switches.

To enable FSCM the following steps should be performed:

1. Enable the FSCM in the device Configuration register, DEVCFG1, by configuring the FCKSM<1:0> bits to '00'.

01 = Clock Switching is enabled, FSCM is disabled

00 = Clock Switching and FSCM are enabled

- 2. Select the desired mode HS, XT, or EC using FNOSC<2:0> in DEVCFG1.
- Select POSC as the default oscillator in the device Configuration register, DEVCFG1 by configuring FNOSC<2:0> = 010 without PLL or 011 with PLL.

If the PLL is to be used:

- Select the appropriate Configuration bits for the PLL input divider to scale the input frequency to be between 4 MHz and 5 MHz using FPLLIDIV<2:0> (DEVCFG2<2:0>).
- 2. Select the desired PLL multiplier using FPLL-MULT<2:0> (DEVCFG2<6:4>).
- 3. Select the desired PLL output divider using FPLLODIV<2:0> (DEVCFG2<18:16>).

If a FSCM interrupt is desired when a FSCM event occurs, the following steps should be performed during start-up code:

- 1. Clear the FSCM interrupt bit FSCMIF (IFS1<14>).
- Set the Interrupt priority FSCMIP<2:0> (IPC8<12:10>) and subpriority FSCMIS<1:0> (IPC8<9:8>).
- Set the FSCM Interrupt Enable bit FSCMIE (IEC1<14>)

Note: The Watchdog Timer, if enabled, will continue to count at the same rate regardless of the SYSCLK frequency. Care must be taken to service the WDT after a Fail-Safe Clock Monitor event, taking into account the change in SYSCLK.

4.2.5.1 FSCM Delay

On a POR, BOR or wake from Sleep mode event, a nominal delay (TFSCM) may be inserted before the FSCM begins to monitor the system clock source. Refer to **Section 5.0 "Resets"** for FSCM delay timing information.

The TFSCM interval is applied whenever the FSCM is enabled and the HS, HSPLL, XT, XTPLL, or SOSC Oscillator modes are selected as the system clock.

Note:	Please	refer	to	the	Electrical
	Characte	eristics	sectio	on fo	r TFSCM
	specifica	tion valu	les.		

4.2.5.2 FSCM and Slow Oscillator Start-up

A slow oscillator start-up will not generate a FSCM event. The FSCM does not begin monitoring until the source to be monitored is running. If the oscillator does not start-up the device will not run due to the lack of a clock source. To detect the failure and prevent this the user should use Two-Speed Start-Up to allow the device to run using the FRC oscillator while the POSC oscillator starts up. The COSC<2:0> bits can then be polled to test for the clock switch to POSC. Refer to **Section 4.2.4 "Two-Speed Start-up"** for further information.

4.2.5.3 FSCM and Slow Clock Sources

Use of the FSCM with slow clock sources (below 100 kHz) is not recommended. Slow clock sources may cause the FSCM to incorrectly detect a clock failure event.

4.2.5.4 FSCM and WDT

The FSCM and the WDT both use the LPRC oscillator as their time base. In the event of a clock failure, the WDT is unaffected and continues to run.

4.2.6 CLOCK SWITCHING OPERATION

With few limitations, applications are free to switch between any of the four clock sources (POSC, SOSC, FRC and LPRC) under software control and at any time. To limit the possible side effects that could result from this flexibility, PIC32MX3XX/4XX devices have a safeguard lock built into the switch process.

Note: Primary Oscillator mode has three different submodes (XT, HS and EC) which are determined by the POSCMD Configuration bits in DEVCFG1. While an application can switch to and from Primary Oscillator mode in software, it cannot switch between the different primary submodes without reprogramming the device. Note: The device does not prevent changing the PLL postscaler or multiplier values on the clock source that is in use. The device will not permit direct switching between PLL clock sources. The user should not change the PLL multiplier values or postscaler values when running from the affected PLL source. To perform either of the above clock switching functions, the clock switch should be performed in two steps. The clock source should first be switched to a non-PLL source, such as FRC, and then switched to the desired source. This requirement only applies to PLL-based clock sources.

4.2.6.1 Enabling Clock Switching

To enable clock switching, the FCKSM1 Configuration bit (DEVCFG1<15>) must be programmed to '0'. If the FCKSM1 Configuration bit is unprogrammed (= 1), the clock switching function and Fail-Safe Clock Monitor function are disabled. This is the default setting.

The NOSC control bits (OSCCON<10:8>) do not control the clock selection when clock switching is disabled. However, the COSC bits (OSCCON<14:12>) will reflect the clock source selected by the FNOSC Configuration bits.

The OSWEN control bit (OSCCON<0>) has no effect when clock switching is disabled. It is held at '0' at all times.

4.2.6.2 Oscillator Switching Sequence

At a minimum, performing a clock switch requires the following sequence:

- 1. If desired, read the COSC<2:0> bits (OSCCON<14:12>) to determine the current oscillator source.
- 2. Perform the unlock sequence to allow a write to the OSCCON register. The unlock sequence has critical timing requirements and should be performed with interrupts and DMA disabled.
- Write the appropriate value to the NOSC<2:0> control bits (OSCCON<10:8>) for the new oscillator source.
- 4. Set the OSWEN bit (OSCCON<0>) to initiate the oscillator switch.
- 5. Optionally perform the lock sequence to lock the OSCCON. The lock sequence must be performed separately from any other operation.

Once the basic sequence is completed, the system clock hardware responds automatically as follows:

 The clock switching hardware compares the COSC<2:0> Status bits with the new value of the NOSC control bits. If they are the same, then the clock switch is a redundant operation. In this case, the OSWEN bit is cleared automatically and the clock switch is aborted.

- The new oscillator is turned on by the hardware if it is not currently running. If a crystal oscillator must be turned on, the hardware will wait until the Oscillator Start-up timer (OST) expires. If the new source is using the PLL, then the hardware waits until a PLL lock is detected (LOCK = 1).
- The hardware clears the OSWEN bit to indicate a successful clock transition. In addition, the NOSC bit values are transferred to the COSC Status bits.
- 4. The old clock source is turned off at this time if the clock is not being used by any modules.

Note: The processor will continue to execute code throughout the clock switching sequence. Timing-sensitive code should not be executed during this time.

The following is a recommended code sequence for a clock switch:

- 1. Disable interrupts and DMA prior to the system unlock sequence.
- 2. Execute the system unlock sequence by writing the Key values of 0xAA996655 and 0x556699AA to the SYSKEY register in two back-to-back assembly or 'C' instructions.
- 3. Write the new oscillator source value to the NOSC control bits.
- 4. Set the OSWEN bit in the OSCCON register to initiate the clock switch.
- Write a non-key value (such as 0x12345678) to the SYSKEY register to perform a lock. Continue to execute code that is not clock-sensitive (optional).
- 6. Check to see if OSWEN is '0'. If it is, the switch was successful. Loop until the bit is '0'.
- 7. Re-enable interrupts and DMA.
 - Notes: There are no timing requirements for the steps other than the initial back-to-back writing of the Key values to perform the unlock sequence. The unlock sequence unlocks all registers that are secured by the lock function. It is

recommended that amount to time is the system is unlock is kept to a minimum. The core sequence for unlocking the OSCCON register and initiating a clock switch is shown in Example 4-2.

4.2.6.3 Clock Switching Considerations

When incorporating clock switching into an application, users should keep certain things in mind when designing their code.

- The SYSLOCK unlock sequence is timing critical. The two Key values must be written back-to-back with no in-between peripheral register access. To prevent unintended peripheral register accesses, it is recommended that all interrupts and DMA transfers are disabled.
- The system will not relock automatically. The user should perform the relock sequence as soon after the clock switch as is possible.
- The unlock sequence unlocks other registers such as the those related to Real-Time Clock control.
- If the destination clock source is a crystal oscillator, the clock switch time will be dictated by the oscillator start-up time.
- If the new clock source does not start, or is not present, the OSWEN bit will remain set.
- A clock switch to a different frequency will affect the clocks to peripherals. Peripherals may require reconfiguration to continue operation at the same rate as they did before the clock switch occurred.
- If the new clock source uses the PLL, a clock switch will not occur until lock has been achieved.
- If the WDT is used, care must be taken to ensure it can be serviced in a timely manner at the new clock rate.

Note: The application should not attempt to switch to a clock with a frequency lower than 100 kHz when the Fail-Safe Clock Monitor is enabled. Clock switching in these instances may generate a false oscillator fail event and result in a switch to the Internal Fast RC oscillator.

Note: The device does not prevent changing the PLL postscaler or multiplier values on the clock source that is in use. The device will not permit direct switching between PLL clock sources. The user should not change the PLL multiplier values or postscaler values when running from the affected PLL source. To perform either of the above clock switching functions, the clock switch should be performed in two steps. The clock source should first be switched to a non-PLL source, such as FRC, and then switched to the desired source. This requirement only applies to PLL-based clock sources.

EXAMPLE 4-2: PERFORMING A CLOCK SWITCH

```
SYSKEY = 0x12345678;
                                      // write invalid key to force lock
SYSKEY = 0xAA996655;
                                      // Write Keyl to SYSKEY
SYSKEY = 0x556699AA;
                                      // Write Key2 to SYSKEY
                                      // OSCCON is now unlocked
                                      // make the desired change
                                      // This can be in 'C' or assembly
OSCCONCLR = 111 \ll 16;
                                      // clear the PLL multiplier bits
OSCCONSET = 101 \ll 16;
                                     // set he new PLL multiplier value
OSCCONSET = 1;
                                      // request clock switch
                                      // Relock the SYSKEY
SYSKEY = 0x12345678;
                                      // Write any value other than Keyl or Key2
                                      // OSCCON is relocked
```

4.2.6.4 Entering Sleep Mode During a Clock Switch

If the device enters Sleep mode during a clock switch operation, the clock switch operation is aborted. The processor keeps the old clock selection and the OSWEN bit (OSCCON<0>) is cleared. The WAIT instruction is then executed normally.

4.2.6.5 SOSC Control

The SOSC can be used by modules, as well as the CPU. Therefore, the SOSC is controlled by a combination of software and hardware. Setting the SOSCEN bit (OSCCON<1>) to a '1' enables the SOSC. The SOSC is disabled when it is not being used by the CPU module and the SOSCEN bit is '0'. If the SOSC is being used as SYSCLK, such as after a clock switch, it cannot be disabled by writing to the SOSCEN bit. If the SOSC is enabled by the SOSCEN bit, it will continue to operate when the device is in SLEEP. To prevent inadvertent clock changes the OSCCON register is locked. It must be unlocked prior to software enabling or disabling the SOSC.

4.3 Input/Output Pins

The pins used by the POSC and SOSC are shared by other peripherals modules. Table shows the function of these shared pins in the available oscillator modes. When the pins are not used by a oscillator they are available for use as general I/O pins or by use by a peripheral sharing the pin.

TABLE 4-5: CONFIGURATION OF PINS ASSOCIATED WITH THE OSCILLATOR MODULE

Pin Name	Clock Mode	Configuration Bit Fleld ⁽¹⁾	TRIS	Pin Type
OSCI	HS, HSPLL, XT, XTPLL	COSC<2:0>, POSCMD<1:0>	Х	OSC
OSCO	HS, HSPLL, XT, XTPLL	COSC<2:0>, POSCMD	Х	OSC
OSCI	EC, ECPLL	COSC<2:0>, POSCMD	Х	CLOCK IN
OSCO	EC, ECPLL	COSC<2:0>, POSCMD, OSCOFNC	Х	PBCLK OUT
OSCO	EC, ECPLL	COSC<2:0>, POSCMD, OSCOFNC	Input	INPUT
OSCO	EC, ECPLL	COSC<2:0>, POSCMD, OSCOFNC	OUTPUT	Ουτρυτ
N/A	FRC, FRCPLL, FRCDIV16, FRCDIV, LPRC	COSC<2:0>	Х	GPIO
N/A	FRC, FRCPLL, FRCDIV16, FRCDIV, LPRC	COSC<2:0>	Х	GPIO
N/A	FRC, FRCPLL, FRCDIV16, FRCDIV, LPRC	COSC<2:0>	Х	GPIO
N/A	FRC, FRCPLL, FRCDIV16, FRCDIV, LPRC	COSC<2:0>	Х	GPIO
SOSCI	SOSC	COSC<2:0>	Х	OSC
SOSCO	SOSC	COSC<2:0>	Х	OSC

Note 1: During device start-up, the device oscillator configuration data is copied from device configuration to COSC.

4.3.1 OSCI AND OSCO PIN FUNCTIONS IN NON-EXTERNAL OSCILLATOR MODES

When the primary oscillator (POSC) on OSCI and OSCO is not configured as a clock source the OSCI pin is automatically reconfigured as a digital I/O. In this configuration, as well as when the primary oscillator is configured for EC mode (POSCMD1:POSCMD0 = 00), the OSCO pin can also be configured as a digital I/O by programming the OSCIOFCN Configuration bit.

When OSCIOFCN is unprogrammed ('1'), a PBCLK is available on OSCO for testing or synchronization purposes. With OSCIOFCN programmed ('0'), the OSCO pin becomes a general purpose I/O pin. In both of these configurations, the feedback device between OSCI and OSCO is turned off to save current.

4.3.2 SOSCI AND SOCI PIN FUNCTIONS IN NON-EXTERNAL OSCILLATOR MODES

When the secondary oscillator (SOSC) on SOSCI and SOSCO pin is not configured as a clock source the pins are automatically reconfigured as a digital I/O.

NOTES:

5.0 RESETS

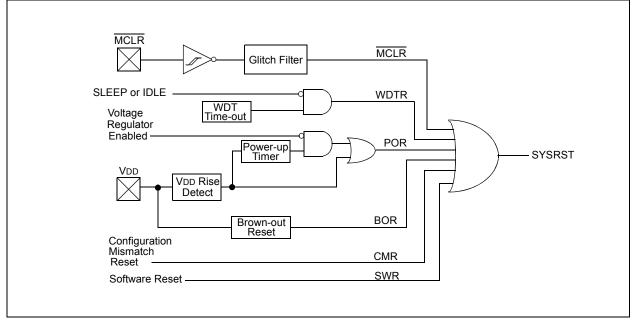

Note:	This data sheet summarizes the features of
	the PIC32MX3XX/4XX family of devices. It
	is not intended to be a comprehensive refer-
	ence source. Refer to the "PIC32MX Family
	Reference Manual" (DS61132) for a
	detailed description of this peripheral.

The Reset module combines all Reset sources and controls the device Master Reset signal, SYSRST. The following is a list of device Reset sources:

- · POR: Power-on Reset
- MCLR: Master Clear Reset Pin
- SWR: Software Reset
- WDTR: Watchdog Timer Reset
- · BOR: Brown-out Reset
- CMR: Configuration Mismatch Reset

A simplified block diagram of the Reset module is shown in Figure 5-1.

REGISTER 5-2: RSWRST: SOFTWARE RESET REGISTER

1 = Enable software reset event

Note: The system unlock sequence must be performed before the SWRST bit can be written. A read must follow the write of this bit to generate a Reset.

5.2 Reset Modes

The PIC32MX3XX/4XX internal device Reset signal is SYSRST and can be generated from multiple Reset sources, such as <u>POR</u> (Power-on Reset), BOR (Brown-out Reset), MCLR (Master Clear Reset), WDTO (Watchdog Time-out Reset), SWR (Software Reset) and CMR (Configuration Mismatch Reset). A Reset source sets a corresponding status bit in the RCON register to indicate the type of Reset (see Register 5-1). A system Reset is active at first the POR and asserted until device configuration settings are loaded and the clock oscillator sources become stable. The system Reset is then deasserted allowing the CPU to start fetching code after 8 system clock cycles (SYS-CLK).

5.2.1 POWER-ON RESET (POR)

A power-on event generates an internal Power-on Reset pulse when a VDD rise is detected above VPOR. The device supply voltage characteristics must meet the specified starting voltage and rise rate requirements to generate the POR pulse. In particular, VDD must fall below VPOR before a new POR is initiated. For more information on the VPOR and VDD rise rate specifications, refer to **Section 30.0 "Electrical Characteristics"** of this device family data sheet.

5.2.2 MCLR RESET (EXTR)

Whenever the MCLR pin is driven low, the device asynchronously asserts SYSRST provided the input pulse on MCLR is longer than a certain minimum width, as specified in **Section 30.0 "Electrical Characteristics"** of this device family data sheet.

MCLR provides a filter to minimize the effects of noise and to avoid unwanted Reset conditions. The EXTR bit (RCON<7>) is set to indicate the MCLR Reset.

5.2.3 SOFTWARE RESET (SWR)

The PIC32MX3XX/4XX CPU core doesn't provide a specific RESET "instruction"; however, a hardware Reset can be performed in software (Software Reset) by executing a Software Reset command sequence:

- Write the system unlock sequence
- Set bit, SWRST (RSWRST<0>) = 1
- Read RSWRST register Reset occurs
- Follow with "while(1);" or 4 "NOP" instructions

Writing a '1' to the RSWRST register sets bit SWRST, arming the Software Reset. The subsequent read of the RSWRST register triggers the Software Reset, which should occur on the next clock cycle following the read operation. To ensure no other user code is executed before the Reset event occurs, it is recommended that 4 'NOP' instructions or a "while(1)," statement be placed after the READ instruction.

The SWR Status bit (RCON<6>) is set to indicate the Software Reset.

EXAMPLE 5-1: SOFTWARE RESET COMMAND SEQUENCE

```
/* The following code illustrates a software Reset */
// assume interrupts are disabled
// assume the DMA controller is suspended
// assume the device is locked
/* perform a system unlock sequence */
// starting critical sequence
SYSKEY = 0xaa996655; //write first unlock key to SYSKEY
SYSKEY = 0x556699aa //write second unlock key to SYSKEY
/* set SWRST bit to arm reset */
RSWRSTSET = 1;
/* read RSWRST register to trigger reset */
unsigned int dummy;
dummy = RSWRST;
/* prevent any unwanted code execution until reset occurs*/
while(1);
```

5.2.4 WATCHDOG TIMER TIME-OUT RESET (WDTR)

A Watchdog Timer time-out causes the device Reset, SYSRST, to be asserted asynchronously. Note that a WDT time-out during SLEEP or IDLE mode will wake-up the processor and branch to the PIC32MX3XX/4XX Reset vector, but not reset the processor. The only bits affected are WDTO and the SLEEP or IDLE bits in the RCON register. For more information, refer to **Section 26.0 "Watchdog Timer"**.

Note: In this document, a distinction is made between a power mode as it is used in a specific module, and a power mode as it is used by the device, e.g., Sleep mode of the comparator and SLEEP mode of the CPU. To indicate which type of power mode is intended, uppercase and lowercase letters (Sleep, Idle, Debug) signify a module power mode, and all uppercase letters (SLEEP, IDLE, DEBUG) signify a device power mode.

5.2.5 BROWN-OUT RESET (BOR)

PIC32MX3XX/4XX devices have a simple brown-out capability. If the voltage supplied to the regulator is inadequate to maintain a regulated level, the regulator Reset circuitry will generate a Brown-out Reset. This event is captured by the BOR flag bit (RCON<1>). Refer to **Section 30.2 "AC Characteristics and Timing Param**eters" for further details.

5.2.6 CONFIGURATION MISMATCH RESET

To maintain the integrity of the stored configuration values, all device Configuration bits are implemented as a complementary set of register bits. For each bit, as the actual value of the register is written as '1', a complementary value, '0', is stored into its corresponding background register and vice versa. The bit pairs are compared every time, including Sleep mode. During this comparison, if the Configuration bit values are not found opposite to each other, a Configuration Mismatch event is generated which causes a device Reset.

If a device Reset occurs as a result of a Configuration Mismatch, the CM bit (RCON<9>) is set.

5.3 Reset States

5.3.1 SPECIAL FUNCTION REGISTER RESET STATES

Most of the Special Function Registers (SFRs) associated with the PIC32MX3XX/4XX CPU and peripherals are reset to a particular value at a device Reset. Refer to the corresponding data sheet section for a peripheral's SFR details. The Reset value for each SFR will depend on the type of Reset.

5.3.2 CONFIGURATION WORD REGISTER RESET STATES

All Reset conditions force the Flash Configuration Word registers to be re-loaded. However, a POR forces Flash Configuration Word registers to be reset prior to being reloaded. For all other Reset conditions, the Flash Configuration Word registers are not reset prior to being re-loaded. This difference accommodates MCLR assertions during Debug mode without affecting the state of the debug operations.

5.3.3 RCON REGISTER STATES

Status bits from the RCON register are set or cleared differently in different Reset situations, as indicated in Table 5-2. The RCON bits only serve as status bits. The user may set or clear any of the bits at any time during code execution. Setting a particular Reset bit in software will not cause a device Reset to occur. The RCON register also has other bits associated with the Watchdog Timer and device power-saving states.

TABLE 5-2:	STATUS BITS, INITIAL	IZATION CONDITIC	ON FO	JK KC	ON R	EGIS	IER	
					•	0		

Condition	Program Counter	EXTR	SWR	WDTO	SLEEP	IDLE	CM	BOR	POR

Interrupt Exit from Idle Mode	Vector ⁽¹⁾	u	u	0	u	1 (2)	u	u	u
Interrupt Exit from Sleep Mode	Vector ⁽¹⁾	u	u	0	1 (2)	u	u	u	u

Legend: u = unchanged

Note 1: Depends on Interrupt source.

2: SLEEP and IDLE bits states defined by previously executed WAIT instruction.

5.4 Using the RCON Status Bits

The user can read the RCON register after any device Reset to determine the cause of the Reset. The status bits in the RCON register should be cleared after they are read so that the next RCON register value after a device Reset will be meaningful.

TABLE 5-3:RESET FLAG BIT OPERATION

Flag Bit	Set by:	Cleared by:
POR (RCON<0>)	POR	User Software
BOR (RCON<1>)	POR, BOR	User Software
EXTR (RCON<7>)	MCLR Reset	User Software, POR, BOR
SWR (RCON<6>)	Software Reset Command	User Software, POR, BOR
CMR (RCON<9>	Configuration Mismatch	User Software, POR, BOR
WDTO (RCON<4>)	WDT Time-Out	User Software, POR, BOR
SLEEP (RCON<3>)	WAIT Instruction	User Software, POR, BOR
IDLE (RCON<2>)	WAIT Instruction	User Software, POR, BOR

Note: All Reset flag bits may be set or cleared by the user software.

5.4.1 DEVICE RESET TO CODE EXECUTION START TIME

The delay between the end of a Reset event and when the device actually begins to execute code is determined by two main factors: the type of Reset and the system clock source coming out of the Reset. The code execution start time for various types of device Resets are summarized in Table 5-4. Individual delays are characterized in Section 30.2 "AC Characteristics and Timing Parameters".

Reset Type	Clock Source	Clock Source Code Execution System		FSCM Delay	Notes
POR	EC, FRC, FRCDIV, LPRC	TPOR + TRST + TSTARTUP	_		1, 2, 3, 7
	ECPLL, FRCPLL	TPOR + TRST + TSTARTUP	TLOCK	TFSCM	1, 2, 3, 5, 6, 7
	XT, HS, SOSC	TPOR + TRST + TSTARTUP	Tost	TFSCM	1, 2, 3, 4, 6, 7
	XTPLL	TPOR + TRST + TSTARTUP	TOST + TLOCK	TFSCM	1, 2, 3, 4, 5, 6, 7
BOR	EC, FRC, FRCDIV, LPRC	Trst + Tstartup	—	_	2, 3, 7
	ECPLL, FRCPLL	Trst + Tstartup	TLOCK	TFSCM	2, 3, 5, 6, 7
	XT, HS, SOSC	Trst + Tstartup	Tost	TFSCM	2, 3, 4, 6, 7
	XTPLL	Trst + Tstartup	TOST + TLOCK	TFSCM	2, 3, 4, 5, 6, 7
MCLR	Any Clock	Trst + Tstartup	—		3, 7
WDTO	Any Clock	Trst + Tstartup	—	_	3, 7
SWR	Any Clock	Trst + Tstartup	—	_	3, 7
CMR	Any Clock	Trst + Tstartup	—	_	3, 7

TABLE 5-4:CODE EXECUTION START TIME FOR VARIOUS DEVICE RESETS

Note 1: TPOR = Power-on Reset delay.

2: TRST = TVREG if on-chip regulator is enabled or TPWRT if on-chip regulator is disabled.

3: TSTARTUP = Load configuration settings, and depending on the oscillator settings, may include TOST, TLOCK and TFSCM.

- 4: TOST = Oscillator Start-up Timer.
- **5:** TLOCK = PLL lock time.
- **6**: TFSCM = Fail-Safe Clock Monitor delay.

7: Included is a required delay of 8 system clock cycles before the Reset to the CPU core is deasserted.

5.5 Interrupts

There are no interrupts for this module.

5.6 I/O Pin Control

There are not I/O pin controls associated with this module.

NOTES:

6.0 MEMORY ORGANIZATION

Note:	This data sheet summarizes the features of						
	the PIC32MX3XX/4XX family of devices. It						
	is not intended to be a comprehensive refer-						
	ence source. Refer to the "PIC32MX Family						
	Reference Manual" (DS61132) for a						
	detailed description of this peripheral.						

PIC32MX3XX/4XX microcontrollers provides 4 GB of unified virtual memory address space. All memory regions including program, data memory, SFRs, and Configuration registers reside in this address space at their respective unique addresses. The program and data memories can be optionally partitioned into user and kernel memories. In addition, the data memory can be made executable, allowing PIC32MX3XX/4XX to execute from data memory.

Key Features:

- 32-bit native data width
- Separate User and Kernel mode address space
- · Flexible program Flash memory partitioning
- Flexible data RAM partitioning for data and program space
- · Separate boot Flash memory for protected code
- Robust bus exception handling to intercept runaway code.
- Simple memory mapping with Fixed Mapping Translation (FMT) unit
- Cacheable and non-cacheable address regions

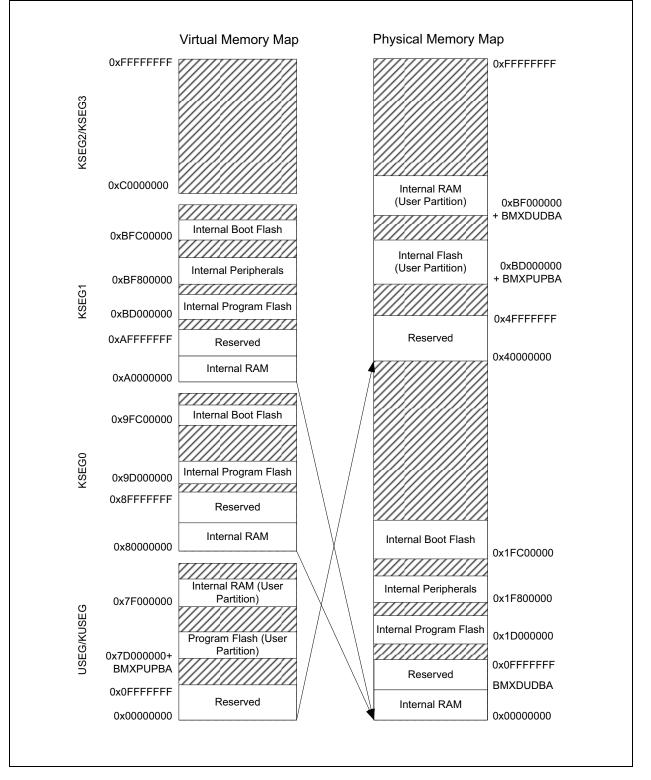

6.1 PIC32MX3XX/4XX Memory Layout

PIC32MX3XX/4XX microcontrollers implement two address spaces: Virtual and Physical. All hardware resources such as program memory, data memory and peripherals are located at their respective physical addresses. Virtual addresses are exclusively used by the CPU to fetch and execute instructions as well as access peripherals. Physical addresses are used by peripherals such as DMA and Flash controller that access memory independently of CPU.

The entire 4 GB virtual address space is divided into two primary regions – user and kernel space. The lower 2 GB of space forms the User mode segment, called useg/kuseg. The upper 2 GB of virtual address space forms the kernel-only space. The kernel space is divided into four segments of 512 MB each: kseg 0, kseg 1, kseg 2 and kseg 3. Only Kernel mode applications can access kernel space memory. The peripheral registers are only visible through kernel space.

The Fixed Mapping Translation (FMT) unit translates the memory segments into corresponding physical address regions. A virtual memory segment may also be cached, provided the cache module is available on the device. Please note that the kseg 1 memory segment is not cacheable, while kseg 0 and useg/kuseg are cacheable.

6.3 User and Kernel Memory Areas

The two modes of operation of the PIC32MX3XX/4XX core are User mode and Kernel mode. To support these modes, the virtual address space is also divided into two segments, kernel segments and user segments. The lower 2 gigabytes of virtual addresses form the User mode partition, and the upper 2 gigabytes forms the Kernel mode partition.

Most application will run only in Kernel mode. For these applications, the entire program can reside in the kernel address space providing full access to all resources.

FIGURE 6-2: USER/KERNEL ADDRESS SEGMENTS

0xFFFFFFFF		
	KERNEL SEGMENTS (KSEG 0,1,2,3)	
0x80000000 0x7FFFFFF

0x00000000		

6.4 PIC32MX3XX/4XX Address Map

Table 6-2showstheaddressmapofthePIC32MX3XX/4XXmicrocontroller.

On reset, the PIC32MX3XX/4XX starts executing code from 0xBFC0_0000 virtual address which reside in the kseg1 segment (non cacheable segment).

6.4.1 PHYSICAL MEMORY ADDRESS

The Kernel Program Flash address space starts at physical address 0x1D000000, whereas the user program flash space starts at physical address 0xBD000000 + BMXPUPBA register value.

Similarly, the internal RAM is also divided into Kernel and User partitions. The kernel RAM space starts at physical address 0x0000000, whereas the User RAM space starts at physical address 0xBF000000 + BMXDUDBA register value.

By default the entire Flash memory and RAM are mapped to the Kernel mode application only.

		Virtual Addresses		Physical Addresses		Size in Bytes
	Memory Type	Begin Address	End Address	Begin Address	End Address	Calculation
Kernel Address Space	Boot Flash	0xBFC00000	0xBFC02FFF	0x1FC00000	0x1FC02FFF	12 KB

TABLE 6-2: PIC32MX3XX/4XX ADDRESS MAP

Note 1: Program Flash virtual addresses in the non-cacheable range (KSEG1).

2: Program Flash virtual addresses in the cacheable and prefetchable range (KSEG0).

3: The RAM size varies between PIC32MX3XX/4XX device family members.

6.5 Program Flash Memory Wait States

For optimal performance, PFMWS(CHECON<2:0>) must be programmed to the minimum value possible. There are two parameters that determine this value:

Flash Access Time – The Flash access time is 50 nSec for the PIC32MX3XX/4XX processor family.

CPU Core frequency – The Core frequency is programmable. Care must be taken when changing frequencies to make sure that there are enough Wait states to prevent any Flash memory access timing violations.

To find out the number of flash Wait states required, divide the core clock frequency (in MHz) by 20 and take the integer part of the result. The value that is written to PFMWS (CHECON<2:0>) is one less. For example, core clock frequency is 72 MHz. The number of Wait states will be 72/20 = 3.6, i.e., 3 Wait states. Therefore the actual value written to PFMWS bits will be 2.

6.6 Program Flash Memory Partitioning

The Program Flash Memory can be partitioned for User and Kernel mode programs as shown in Figure 6-3.

At Reset, the User mode partition does not exist (BMX-PUPBA is initialized to '0'). The entire Program Flash Memory is mapped to Kernel mode program space starting at virtual address KSEG1: 0xBD000000 (or KSEG0: 0x9D000000). To set up a partition for the User mode program, initialize BMXPUPBA as follows:

BMXPUPBA = BMXPFMSZ – USER_FLASH_PGM_SZ

The USER_FLASH_PGM_SZ is the partition size of the User mode program. BMXPFMSZ is the bus matrix register that holds the total size of Program Flash Memory.

Example:

Assuming the PIC32MX3XX/4XX device has 512 Kbytes of Flash memory, the BMXPFMSZ will contain 0x00080000.

To create a user Flash program partition of 20 Kbytes (0x5000):

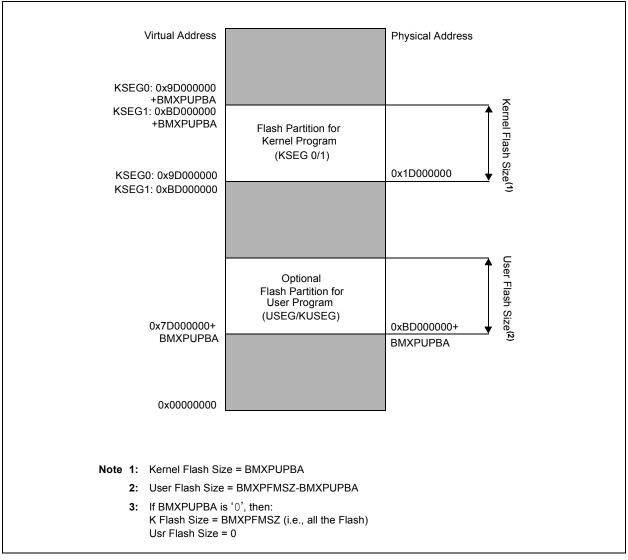

BMXPUPBA = 0x80000 - 0x5000 = 0x7B000

The size of the user Flash will be 20K and the size left for the kernel Flash will be 512k - 20k = 492K.

The user Flash partition will extend from 0x7D07B000 to 0x7D07FFFF (virtual addresses).

The Kernel mode partition always starts from KSEG1: 0xBD000000 or KSEG0: 0x9D000000. In the above example, the kernel partition will extend from 0xBD000000 to 0xBD07AFFF (492 Kbytes in size).

FIGURE 6-3: FLASH PARTITIONING

6.6.1 RAM PARTITIONING

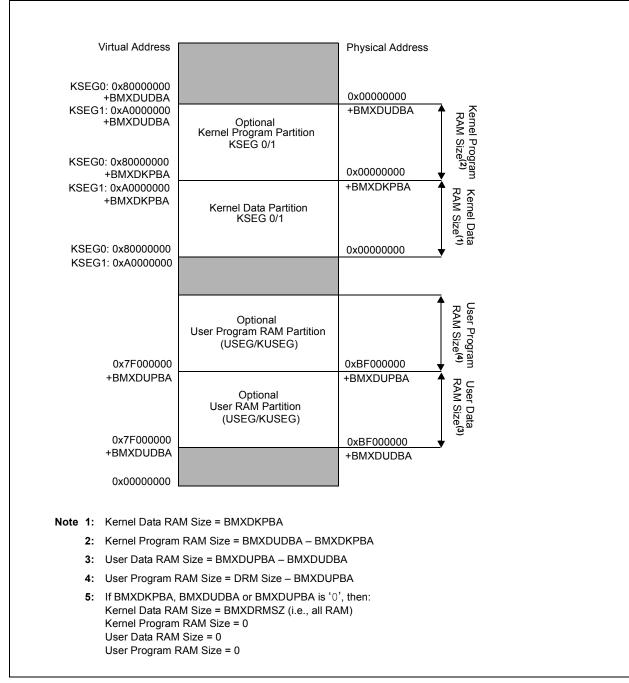

The RAM memory can be divided into 4 partitions. These are:

- 1. Kernel Data
- 2. Kernel Program
- 3. User Data
- 4. User Program

In order to execute from data RAM, a kernel or user program partition must be defined. At Power-on Reset, the entire data RAM is assigned to the kernel data partition. This partition always starts from the base of the data RAM. See Figure 6-4 for details.

The registers controlling the RAM partitions are BMXD-KPBA, BMXDUDBA, and BMXDUPBA. For a detailed discussion on how to use these registers for partitioning the RAM, please refer to the Memory Organization section of the PIC32MX3XX/4XX Family Reference Manual (DS61132).

6.6.2 ADDRESS DECODE

Table 6-3 shows the address map for system resources available to the CPU when it is operating in either User mode or Kernel mode.

Table 6-4 shows the address map for system resources mapped in KSEG0 that are available to the CPU when it is operating in Kernel mode.

Table 6-5 shows the address map for system resources mapped in KSEG1 that are available to the CPU when it is operating in Kernel mode.

TABLE 6-6: PERIPHERAL ADDRESS TABLE

PIC32MX3XX/4XX

NOTES:

7.0 FLASH PROGRAM MEMORY

Note:	This data sheet summarizes the features of the PIC32MX3XX/4XX family of devices. It						
	is not intended to be a comprehensive refer-						
	ence source. Refer to the "PIC32MX Family						
	Reference Manual" (DS61132) for a						
	detailed description of this peripheral.						

The PIC32MX3XX/4XX of devices contain internal program Flash memory for executing user code. There are three methods by which the user can program this memory:

- 1. Run-Time Self Programming (RTSP)
- 2. In-Circuit Serial Programming[™] (ICSP[™])
- 3. EJTAG Programming

RTSP is performed by software executing from either Flash or RAM memory. EJTAG is performed using the EJTAG port of the device and a EJTAG capable programmer. ICSP is performed using a serial data connection to the device and allows much faster programming times than RTSP. RTSP techniques are described in this chapter. The ICSP and EJTAG methods are described in the "*PIC32MX3XX/4XX Programming Specification*" (DS61145) document, which may be downloaded from the Microchip web site.

REGISTER 7-1: NVMCON: PROGRAMMING CONTROL REGISTER (CONTINUED)

- bit 3-0 **NVMOP<3:0>**: NVM Operation bits
 - 0111 = Reserved
 - 0110 = No operation

0101 = Program Flash (PFM) erase operation: erases PFM, if all pages are not write-protected

0100 = Page erase operation: erases page selected by NVMADDR, if it is not write-protected

0011 = Row program operation: programs row selected by NVMADDR, if it is not write-protected

0010 = No operation

0001 = Word program operation: programs word selected by NVMADD,R if it is not write-protected 0000 = No operation

7.2 RTSP Operation

RTSP allows the user code to modify Flash program memory contents. The device Flash memory is divided into two logical Flash partitions: the Program Flash Memory (PFM), and the Boot Flash Memory (BFM). The last page in Boot Flash Memory contains the DEBUG Page, which is reserved for use by the debugger tool while debugging.

The program Flash array for the PIC32MX3XX/4XX device is built up of a series of rows. A row contains 128 32-bit instruction words or 512 bytes. A group of 8 rows compose a page; which, therefore, contains $8 \times 512 =$ 4096 bytes or 1024 instruction words. A page of Flash is the smallest unit of memory that can be erased at a single time. The program Flash array can be programmed in one of two ways:

- Row programming, with 128 instruction words at a time.
- Word programming, with 1 instruction word at a time.

The CPU stalls (waits) until the programming operation is finished. The CPU will not execute any instruction, or respond to interrupts, during this time. If any interrupts occur during the programming cycle, they remain pending until the cycle completes.

7.3 Control Registers

There are two SFRs used to erase and write the PFM: NVMCON and NVMKEY.

The NVMCON register (Register 7-1) controls which blocks are to be erased, which memory block is to be programmed and the start of the programming cycle.

NVMKEY is a write-only register that is used for writeprotection. To start a programming or erase sequence, the user must consecutively write 0xAA996655 and 0x556699AA to the NVMKEY register. Interrupts should be disabled. Refer to **Section 7.4** "**Programming Operations**" for further details.

7.4 Programming Operations

A complete programming sequence is necessary for programming or erasing the internal Flash in RTSP mode. A programming operation is nominally 5 ms in duration and the processor stalls (WAITS) until the operation is finished. Setting the NVMWR bit (NVM-CON<15>) starts the operation, and the NVMWR bit is automatically cleared when the operation is finished.

7.4.1 PROGRAMMING ALGORITHM

The user can program one row of program Flash memory at a time. To do this, it is necessary to erase the 8-row erase block containing the desired row. The general process is:

- Read eight rows of program memory (1024 instructions) and store in data RAM.
- 2. Update the program data in RAM with the desired new data.
- 3. Erase the page (see Example 7-1):
- 4. Write the first 128 words from data RAM into the program memory buffers (see Example 7-1).

EXAMPLE 7-1: ERASING FLASH PAGE

 Repeat steps 4 and 5, using the next available 128 words from the block in data RAM by incrementing the value in NVMADDR and NVMASRCADDR, until all 1024 instructions are written back to Flash memory.

For protection against accidental operations, the write initiate sequence for NVMKEY must be used to allow any erase or program operation to proceed. After the programming command has been executed, the user must wait for the programming time until programming is complete.

```
unsigned int NVMUnlock (unsigned int nvmop)
   unsigned int status;
   // Suspend or Disable all Interrupts
   asm volatile ("di %0" : "=r" (status));
    // Enable Flash Write/Erase Operations and Select
   // Flash operation to perform
   NVMCON = 0 \times 8000 \setminus \text{nvmop};
    // Write Keys
   NVMKEY = 0 \times AA996655;
   NVMKEY = 0 \times 556699 AA;
    // Start the operation using the Set Register
   NVMCONSET = 0 \times 8000;
   // Wait for operation to complete
   while (NVMCON & 0x8000);
    // Restore Interrupts
   if (status & 0x0000001
       asm volatile ("ei");
    else
       asm volatile ("di");
    // Return NVMERR and LVDERR Error Status Bits
   return (NVMCON & 0x3000)
}
unsigned int NVMErasePage(void* address)
{
   unsigned int res;
   // Set NVMADDR to the Start Address of page to erase
   NVMADDR = (unsigned int) address;
    // Unlock and Erase Page
   res = NVMUnlock(0x4004);
    // Return Result
    return res;
}
```

EXAMPLE 7-2: ROW PROGRAMMING SEQUENCE

```
unsigned int NVMUnlock (unsigned int nvmop)
    unsigned int status;
    // Suspend or Disable all Interrupts
   asm volatile ("di %0" : "=r" (status));
    // Enable Flash Write/Erase Operations and Select
    // Flash operation to perform
   NVMCON = 0 \times 8000 \ nvmop;
   // Write Keys
   NVMKEY = 0 \times AA996655;
   NVMKEY = 0 \times 556699 AA;
    // Start the operation using the Set Register
   NVMCONSET = 0x8000;
    // Wait for operation to complete
    while (NVMCON & 0x8000);
    // Restore Interrupts
   if (status & 0x0000001
       asm volatile ("ei");
    else
       asm volatile ("di");
    // Return NVMERR and LVDERR Error Status Bits
    return (NVMCON & 0x3000)
}
unsigned int NVMWriteRow (void* address, void* data)
{
   unsigned int res;
    // Set NVMADDR to Start Address of row to program
   NVMADDR = (unsigned int) address;
    // Set NVMSRCADDR to the SRAM data buffer Address
   NVMSRCADDR = (unsigned int) data;
   // Unlock and Write Row
   res = NVMUnlock(0x4003);
    // Return Result
    return res;
}
```

EXAMPLE 7-3: WORD PROGRAMMING SEQUENCE

```
unsigned int NVMUnlock (unsigned int nvmop)
    unsigned int status;
   // Suspend or Disable all Interrupts
   asm volatile ("di %0" : "=r" (status));
    // Enable Flash Write/Erase Operations and Select
    // Flash operation to perform
    NVMCON = 0 \times 8000 \ nvmop;
   // Write Keys
   NVMKEY = 0 \times AA996655;
   NVMKEY = 0 \times 556699 AA;
   // Start the operation using the Set Register
   NVMCONSET = 0x8000;
    // Wait for operation to complete
    while (NVMCON & 0x8000);
   // Restore Interrupts
   if (status & 0x0000001
       asm volatile ("ei");
    else
       asm volatile ("di");
    // Return NVMERR and LVDERR Error Status Bits
    return (NVMCON & 0x3000)
}
unsigned int NVMWriteWord (void* address, unsigned int data)
{
   unsigned int res;

   return (NVMCON & 0x3000)
}
unsigned int NVMErasePFM(void)
{
   unsigned int res;
   // Unlock and Erase Program Flash
   res = NVMUnlock(0x4005);
    // Return Result
   return res;
}
```

PIC32MX3XX/4XX

NOTES:

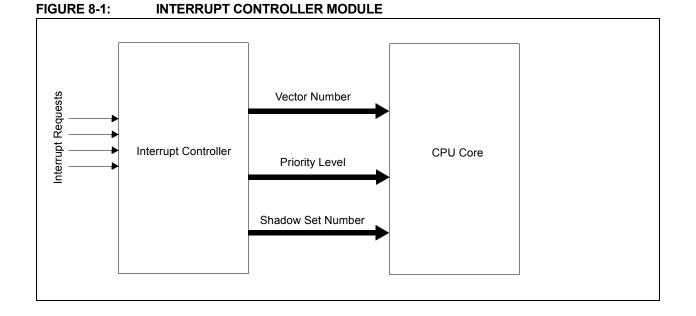

8.0 INTERRUPTS

Note:	This data sheet summarizes the features of							
	the PIC32MX3XX/4XX family of devices. It							
	is not intended to be a comprehensive refer-							
	ence source. Refer to the "PIC32MX Family							
	Reference Manual" (DS61132) for a							
	detailed description of this peripheral.							

PIC32MX3XX/4XX generates interrupt requests in response to interrupt events from peripheral modules. The interrupts module exists external to the CPU logic and prioritizes the interrupt events before presenting them to the CPU.

The PIC32MX3XX/4XX interrupts module includes the following features:

- Up to 96 interrupt sources
- · Up to 64 interrupt vectors
- · Single and Multi-Vector mode operations
- 5 external interrupts with edge polarity control
- · Interrupt proximity timer
- Module Freeze in Debug mode
- 7 user-selectable priority levels for each vector
- 4 user-selectable subpriority levels within each priority
- Dedicated shadow set for highest priority level
- · Software can generate any interrupt
- User-configurable interrupt vector table location
- · User-configurable interrupt vector spacing

Note: Several of the registers cited in this section are not in the interrupt controller module. These registers (and bits) are associated with the CPU. Details about them are available in **Section 2.0 "PIC32MX MCU".**

To avoid confusion, a typographic distinction is made for registers in the CPU. The register names in this section, and all other sections of this manual, are signified by uppercase letters only.CPU register names are signified by upper and lowercase letters. For example, INTSTAT is an Interrupts register; whereas, IntCtl is a CPU register.

8.1 Control Registers

Note:	Each PIC32MX device variant may have						
	one or more Interrupt channels. An 'x'						
	used in the names of control/Status bits						
	and registers denotes the particular chan-						
	nel. Refer to the specific device data						
	sheets for more details.						

The interrupts module consists of the following Special Function Registers (SFRs):

- INTCON: Interrupt Control Register
 INTCONCLR, INTCONSET, INTCONINV: Atomic Bit
 Manipulation, Write-Only Registers for INTCON
- INTSTAT: Interrupt Status Register
 INTSTATCLR, INTSTATSET, INTSTATINV: Atomic
 Bit Manipulation, Write-Only Registers for INTSTAT

- IPTMR: Interrupt Proximity Timer Register IPTMRCLR, IPTMRSET, IPTMRNINV: Atomic Bit Manipulation, Write-Only Registers for IPTMR
- IFS0, IFS1: Interrupt Flag Status Registers IFSxCLR, IFSxSET, IFSxINV: Atomic Bit Manipulation, Write-Only Registers for IFSx
- IEC0, IEC1: Interrupt Enable Control Registers IECxCLR, IECxSET, IECxINV: Atomic Bit Manipulation, Write-Only Registers for IECx
- IPC0 IPC11: Interrupt Priority Control Registers IPCxCLR, IPCxSET, IPCxINV: Atomic Bit Manipulation, Write-Only Registers for IPCx

The following table provides a brief summary of interrupts module related registers. Corresponding registers appear after the summary, followed by a detailed description of each register.

TABLE 8-2: INTERRUPT IRQ AND VECTOR LOCATION (CONTINUED)

Note 1: The "IRQ Number" in Table 8-2 is also the "Interrupt Number" listed in the IFSx, IECx and IPSx register definitions.

8.2 Operation

The interrupt controller is responsible for preprocessing Interrupt Requests (IRQ) from a number of on-chip peripherals and presenting them in the appropriate order to the processor.

Figure 8-2 depicts the process within the interrupt controller module. The interrupt controller is designed to receive up to 96 IRQs from the processor core and from on-chip peripherals capable of generating interrupts. All IRQs are sampled on the rising edge of the SYSCLK and latched in associated IFSx registers. A pending IRQ is indicated by the flag bit being equal to '1' in an IFSx register. The pending IRQ will not cause further processing if the corresponding bit in the Interrupt Enable (IECx) register is clear. The IECx bits act to gate the interrupt flag. If the interrupt is enabled, all IRQs are encoded into a 5-bit wide vector number. The 5-bit vector results in 0 to 63 unique interrupt vector numbers. Since there are more IRQs than available vector numbers, some IRQs share common vector numbers. Each vector number is assigned an interrupt priority level and shadow set number. The priority level is determined by the IPCx register setting of the associated vector. In Multi-Vector mode, all priority level 7 interrupts use a dedicated register set, while in Single Vector mode, all interrupts may receive a dedicated shadow set. The interrupt controller selects the highest priority IRQ among all pending IRQs and presents the associated vector number, priority level and shadow set number to the processor core.

The processor core samples the presented vector information between the 'E' and 'M' stage of the pipeline. If the vector's priority level presented to the core is greater than the current priority indicated by the CPU Interrupt Priority bits IPLx (Status<15:10>), the interrupt is serviced; otherwise, it will remain pending until the current priority is less than the interrupt's priority. When servicing an interrupt, the processor core pushes the program counter into the Exception Program Counter (EPC) register in the CPU and sets Exception Level bit EXL (Status<1>) in the CPU. The EXL bit disables further interrupts until the application explicitly reenables them by clearing the EXL bit. Next, it branches to the vector address calculated from the presented vector number. The INTSTAT register contains the Interrupt Vector Number bits, VEC (INTSTAT<5:0>), and Requested Interrupt Priority bits, RIPLx (INTSTAT<10:8>), of the current pending interrupt. This may not be the same as the interrupt which caused the core to diverge from normal execution.

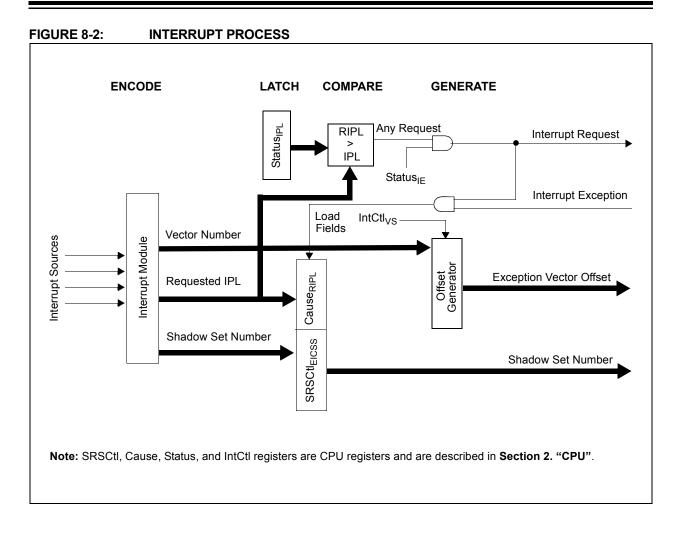

The processor returns to the previous state when the ERET (Exception Return) instruction is executed. ERET clears the EXL bit, restores the program counter and reverts the current shadow set to the previous one.

The PIC32MX3XX/4XX interrupt controller can be configured to operate in one of two modes:

- Single Vector mode all interrupt requests will be serviced at one vector address (mode out of Reset).
- Multi-Vector mode interrupt requests will be serviced at the calculated vector address.

Notes: While the user can, during run time, reconfigure the interrupt controller from Single Vector to Multi-Vector mode (or vice versa), such action is strongly discouraged. Changing interrupt controller modes after initialization may result in undefined behavior.

> The M4K core supports several different interrupt processing modes. The interrupt controller is designed to work in External Interrupt Controller mode.

8.3 Single Vector Mode

On any form of Reset, the interrupt controller initializes to Single Vector mode. When the MVEC (INT-CON<12>) bit is '0', the interrupt controller operates in Single Vector mode. In this mode, the CPU always vectors to the same address.

Note: Users familiar with MIPS32 Architecture must note that the M4K core in PIC32MX3XX/4XX is still operating in External Interrupt Controller (EIC) mode. The PIC32MX3XX/4XX achieves Single Vector mode by forcing all IRQs to use a vector number of 0x00. Because the M4K core in PIC32MX3XX/4XX always operates in EIC mode, the single vector behavior through "Interrupt Compatibility Mode," as defined by MIPS32 Architecture, is not recommended. To configure the CPU in Single Vector mode, the following CPU registers (IntCtl, Cause, and Status) and INT-CON register must be configured as follows:

- EBase ≠ 00000
- VS (IntCtl<9:5>) ≠ 00000
- IV (Cause<23>) = 1
- EXL (Status<1>) = 0
- BEV (Status<22>) = 0
- MVEC (INTCON<12>) = 0
- IE (Status<0>) = 1

EXAMPLE 8-1: SINGLE VECTOR MODE INITIALIZATION

/*	Set the CPO registers for multi-veo Place EBASE at 0xBD000000	ctor interrupt
*/	-	ntrinsic functions to access CPO registers. To find equivalent functions or use inline assembly
		<pre>// Disable all interrupts</pre>
	asm(ur),	// Disable all intellupts
	temp = CP0 GET STATUS();	// Get Status
		// Set BEV bit
	_CP0_SET_STATUS(temp);	
	_CP0_SET_EBASE(0xBD000000);	// Set an EBase value of 0xBD000000
	_CP0_SET_INTCTL(0x00000020);	// Set the Vector Spacing to non-zero value
	<pre>temp = _CP0_GET_CAUSE();</pre>	// Get Cause
	temp $ = 0x00800000;$	// Set IV
	_CP0_SET_CAUSE(temp);	// Update Cause
	<pre>temp = _CP0_GET_STATUS();</pre>	// Get Status
	temp &= 0xFFBFFFFD;	// Clear BEV and EXL
	_CP0_SET_STATUS(temp);	// Update Status
	INTCONCLR = 0x1000;	// Clear MVEC bit
	asm("ei");	// Enable all interrupts

8.4 Multi-Vector Mode

When the MVEC (INTCON<12>) bit is '1', the interrupt controller operates in Multi-Vector mode. In this mode, the CPU vectors to the unique address for each vector number. Each vector is located at a specific offset, with respect to a base address specified by the EBase register in the CPU. The individual vector address offset is determined by the vector space that is specified by the VS bits in the IntCtl register. (The IntCtl register is located in the CPU; refer to **Section 2.0 "PIC32MX MCU"** of this manual for more information.)

To configure the CPU in Multi-Vector mode, the following CPU registers (IntCtl, Cause, and Status) and the INTCON register must be configured as follows:

- EBase ≠ 00000
- VS (IntCtl<9:5>) ≠ 00000
- IV (Cause<23>) = 1
- EXL (Status<1>) = 0
- BEV (Status<22>) = 0
- MVEC (INTCON<12>) = 1
- IE (Status<0>) = 1

EXAMPLE 8-2: MULTI-VECTOR MODE INITIALIZATION

```
/*
  Set the CPO registers for multi-vector interrupt
  Place EBASE at 0xBD000000 and Vector Spacing to 32 bytes
  This code example uses MPLAB C32 intrinsic functions to access CPO registers.
  Check your compiler documentation to find equivalent functions or use inline assembly
* /
  unsigned int temp;
  asm("di");
                                     // Disable all interrupts
  temp = CPO GET STATUS();
                                     // Get Status
  temp |= 0 \times 00400000;
                                     // Set BEV bit
  CP0 SET STATUS(temp);
                                     // Update Status
  CP0 SET EBASE(0xBD000000);
                                     // Set an EBase value of 0xBD000000
  CP0 SET INTCTL(0x00000020);
                                     // Set the Vector Spacing to non-zero value
  temp = _CP0_GET_CAUSE();
                                     // Get Cause
  temp |= 0x00800000;
                                     // Set IV
  CP0 SET CAUSE(temp);
                                     // Update Cause
  temp = CP0 GET STATUS();
                                     // Get Status
  temp &= 0xFFBFFFFD;
                                     // Clear BEV and EXL
  CP0 SET STATUS(temp);
                                     // Update Status
  INTCONSET = 0 \times 1000;
                                     // Set MVEC bit
  asm("ie");
                                     // Enable all interrupts
```

8.5 Interrupt Priorities

8.5.1 INTERRUPT GROUP PRIORITY

The user is able to assign a group priority to each of the interrupt vectors. The groups' priority level bits are located in the IPCx register. Each IPCx register contains group priority bits for four interrupt vectors. The user-selectable priority levels range from 1 (the lowest priority) to 7 (the highest). If an interrupt priority is set to zero, the interrupt vector is disabled for both interrupt and wake-up purposes. Interrupt vectors with a higher priority level preempt lower priority interrupts. The user must move the Requested Interrupt Priority bit of the

Cause register, RIPLx (Cause<15:10>), into the Status register's Interrupt Priority bits, IPLx (Status<15:10>), before re-enabling interrupts. (The Cause and Status registers are located in the CPU; refer to **Section 2.0 "PIC32MX MCU"** of this manual for more information.) This action will disable all lower priority interrupts until the completion of the Interrupt Service Routine.

Note: The Interrupt Service Routine (ISR) must clear the associated interrupt flag in the IFSx register before lowering the interrupt priority level to avoid recursive interrupts.

EXAMPLE 8-3: SETTING GROUP PRIORITY LEVEL

```
/*
The following code example will set the priority to level 2. Multi-Vector initialization
must be performed (See Example 8-2)
*/
IPCOCLR = 0x0000001C; // clear the priority level
IPCOSET = 0x00000008; // set priority level to 2
```

8.5.2 INTERRUPT SUBPRIORITY

The user can assign a subpriority level within each group priority. The subpriority will not cause preemption of an interrupt in the same priority; rather, if two interrupts with the same priority are pending, the interrupt with the highest subpriority will be handled first. The subpriority bits are located in the IPCx register. Each IPCx register contains subpriority bits for four of the interrupt vectors. These bits define the subpriority within the priority level of the vector. The user-selectable subpriority levels range from 0 (the lowest subpriority) to 3 (the highest).

EXAMPLE 8-4: SETTING SUBPRIORITY LEVEL

```
/*
The following code example will set the subpriority to level 2. Multi-Vector initialization
must be performed (See Example 8-2)
*/
IPCOCLR = 0x00000003; // clear the subpriority level
IPCOSET = 0x00000002; // set the subpriority to 2
```

8.6 Interrupt Processing

When the priority of a requested interrupt is greater than the current CPU priority, the interrupt request is taken and the CPU branches to the vector address associated with the requested interrupt. Depending on the priority of the interrupt, the prologue and epilogue of the interrupt handler must perform certain tasks before executing any useful code. The following examples provide recommended prologues and epilogues.

8.6.1 INTERRUPT PROCESSING IN SINGLE VECTOR MODE

When the interrupt controller is configured in Single Vector mode, all of the interrupt requests are serviced at the same vector address. The interrupt handler routine must generate a prologue and an epilogue to properly configure, save and restore all of the core registers, along with General Purpose Registers. At a worst case, all of the modifiable General Purpose Registers must be saved and restored by the prologue and epilogue.

8.6.1.1 Single Vector Mode Prologue

When entering the interrupt handler routine, the interrupt controller must first save the current priority and exception PC counter from Interrupt Priority bits, IPLx (Status<15:10>), and the ErrorEPC register, respectively, on the stack. (Status and ErrorEPC are CPU registers.) If the routine is presented a new register set, the previous register set's stack register must be copied to the current set's stack register. Then, the requested priority may be stored in the IPLx from the Requested Interrupt Priority bits, RIPLx (Cause<15:10>), Exception Level bit, EXL, and Error Level bit, ERL, in the Status register (Status<1> and Status<2>) are cleared and the Master Interrupt Enable bit (Status<0>) is set. Finally, the General Purpose Registers will be saved on the stack. (The Cause and Status registers are located in the CPU.)

8.6.2 INTERRUPT PROCESSING IN MULTI-VECTOR MODE

When the interrupt controller is configured in Multi-Vector mode, the interrupt requests are serviced at the calculated vector addresses. The interrupt handler routine must generate a prologue and an epilogue to properly configure, save and restore all of the core registers, along with General Purpose Registers. At a worst case, all of the modifiable General Purpose Registers must be saved and restored by the prologue and epilogue. If the interrupt priority is set to receive its own General Purpose Register set, the prologue and epilogue will not need to save or restore any of the modifiable General Purpose Registers, thus providing the lowest latency.

8.6.2.1 Multi-Vector Mode Prologue

When entering the interrupt handler routine, the Interrupt Service Routine (ISR) must first save the current priority and exception PC counter from Interrupt Priority bits, IPL (Status<15:10>), and the ErrorEPC register, respectively, on the stack. If the routine is presented a new register set, the previous register set's stack register must be copied to the current set's stack register. Then, the requested priority may be stored in the IPLx from Requested Interrupt Priority bits, RIPLx (Cause<15:10>), Exception Level bit, EXL, and Error Level bit, ERL, in the Status register (Status<1> and Status<2>) are cleared, and the Master Interrupt Enable bit (Status<0>) is set. If the interrupt handler is not presented a new General Purpose Register set, these resisters will be saved on the stack. (Cause and Status are CPU registers; refer to Section 2.0 "PIC32MX MCU" of this manual for more information.)

8.6.2.2 Multi-Vector Mode Epilogue

After completing all useful code of the interrupt handler routine, the original state of the Status and ErrorEPC registers, along with the General Purpose Registers saved on the stack, must be restored. (The Status and ErrorEPC registers are located in the CPU; refer to **Section 2.0 "PIC32MX MCU"** of this manual for more information.)

8.7 External Interrupts

The interrupt controller supports five external interruptrequest signals (INT4-INT0). These inputs are edge sensitive; they require a low-to-high or a high-to-low transition to create an interrupt request. The INTCON register has five bits that select the polarity of the edge detection circuitry: INT4EP (INTCON<4>), INT3EP (INTCON<3>), INT2EP (INTCON<2>), INT1EP (INT-CON<1>) and INT0EP (INTCON<0>).

Note: Changing the external interrupt polarity may trigger an interrupt request. It is recommended that before changing the polarity, the user disables that interrupt, changes the polarity, clears the interrupt flag and re-enables the interrupt.

EXAMPLE 8-11: SETTING EXTERNAL INTERRUPT POLARITY

/*
The following code example will set INT3 to trigger on a high to low transition edge. The CPU
must be set up for either multi or single vector interrupts to handle external interrupts
*/
IECOCLR = 0x00008000; // disable INT3
INTCONCLR = 0x0000008; // clear the bit for falling edge trigger
IFSOCLR = 0x00008000; // clear the interrupt flag
IECOSET = 0x00008000; // enable INT3

8.8 Temporal Proximity Interrupt Coalescing

The PIC32MX3XX/4XX CPU responds to interrupt events as if they are all immediately critical because the interrupt controller asserts the interrupt request to the CPU when the interrupt request occurs. The CPU immediately recognizes the interrupt if the current CPU priority is lower than the pending priority. Entering and exiting an ISR consumes clock cycles for saving and restoring context. Events are asynchronous with respect to the main program and have a limited possibility of occurring simultaneously or close together in time. This prevents the ability of a shared ISR to process multiple interrupts at one time. Interrupt proximity interrupt uses the interrupt proximity timer, IPTMR, to create a temporal window in which a group of interrupts of the same, or lower, priority will be held off. The user can activate temporal proximity interrupt coalescing by performing the following steps:

- Set the TPC<2:0> INTCON<10:8> bit to the preferred priority level. (Setting TPC to zero will disable the proximity timer.)
- · Load the preferred 32-bit value to IPTMR.

The interrupt proximity timer will trigger when an interrupt request of a priority equal, or lower, matches the TPC value.

EXAMPLE 8-12: INTERRUPT PROXIMITY INTERRUPT COALESCING EXAMPLE

```
/*
The following code example will set the Interrupt Proximity Coalescing to trigger on interrupt
priority level of 3 or below and the interrupt timer to be set to 0x12345678.
*/
INTCONCLR = 0x00000700; // clear TPC
IPTMPCLR = 0xFFFFFFF; // clear the timer
INTCONSET = 0x00000300; // set TPC->3
IPTMR = 0x12345678; // set the timer to 0x12345678
```

PIC32MX3XX/4XX

NOTES:

9.0 PREFETCH CACHE

Note: This data sheet summarizes the features of the PIC32MX3XX/4XX family of devices. It is not intended to be a comprehensive reference source. Refer to the *"PIC32MX Family Reference Manual"* (DS61132) for a detailed description of this peripheral.

The Prefetch cache increases performance for applications executing out of the cacheable program flash memory region by implementing instruction caching, data caching and instruction prefetching.

9.1 Features

- 16 Fully Associative Lockable Cache Lines
- 16-byte Cache Lines
- Up to 4 Cache Lines allocated to Data
- 2 Cache Lines with Address Mask to hold repeated instructions
- Pseudo LRU replacement policy
- All Cache Lines are software writable
- · 16-byte parallel memory fetch
- Predictive Instruction Prefetch

REGISTER 9-12: CHEPFABT: PREFETCH CACHE ABORT STATISTICS REGISTER

bit 31-0 CHEPFABT<31:0>: Prefab Abort Count bits

Incremented each time an automatic prefetch cache is aborted due to a non-sequential instruction fetch, load or store.

9.3 Prefetch Configuration

The CHECON register controls the configurations available for instruction and data caching of Program Flash Memory.

In addition to normal instruction caching, the prefetch cache has the ability to cache lines specifically for Flash Memory data.

The CHECON.DCSZ field controls the number of lines allocated to program data caching. Table 9-2 shows the cache line relationship for values of DCSZ. The data caching capability is for read only data such as constants, parameters, table data, etc., that are not modified.

TABLE 9-2: PROGRAM DATA CACHE

DCSZ<1:0>	Lines Allocated to Program Data
00	None
01	Cache Line Number 15
10	Cache Line Number 14 and 15
11	Cache Line Number 12 through 15

The CHECON.PREFEN field controls predictive prefetching, which allows the prefetch module to speculatively fetch the next 16-byte aligned set of instructions.

The prefetch module loads data into the data array only on accesses to cacheable regions (CCA bits = 3).

EXAMPLE 9-1: EXAMPLE CODE: INITIALIZATION CODE FOR PREFETCH MODULE

9.3.1 LINE LOCKING

Each line in the cache can be locked to hold its contents. A line is locked if both LVALID = 1 and LLOCK = 1. If LVALID = 0 and LLOCK = 1, the prefetch module issues a preload request (see below). Locking cache lines may reduce the performance of general program flow. However, if one or two functions calls consume a significant percent of overall processing, locking their address can provide improved performance.

Though any number of lines can be locked, the cache works most efficiently when locking either 1 or 4 lines. If locking 4 lines, choose lines whose line number divide by 4 have the same quotient. This locks an entire LRU group which benefits the LRU algorithm. For example, lines 8, 9, A, and B each have a quotient of 2 when divided by 4.

If cache lines are manually filled, it is recommended that the following sequence be used:

- 1. Choose a cache line to fill.
- 2. Set the Lock and Valid bits of the cache line by writing to CHETAG.
- 3. Write to each word of the cache line by writing to CHEW0, CHEW1, CHEW2, and CHEW3.

EXAMPLE 9-2: EXAMPLE CODE: LOCKING A LINE IN PREFETCH MODULE

```
#define LOCKED_LINE_NUM 3
/* lock first line of funcl() in cache */
CHEACC = (1<<31) | LOCKED_LINE_NUM;
tmp = (unsigned long)func1;
ltagboot = (tmp & 0x00c00000) ? 0 : 1;
CHETAG = (ltagboot<<31) | (tmp & 0x0007fff0) | 6; // locked and invalid</pre>
```

9.3.2 PRELOAD BEHAVIOR

Application code can direct the prefetch module to preform a preload of a cache line and lock it with instructions or data from the flash. The Preload function uses the CHEACC.CHEIDX register field to select the cache line into which the load is directed. Setting CHEACC.CHEWEN to a '1' enables writes to the CHETAG register.

Writing CHETAG.LVALID = 0 and CHETAG.LLOCK = 1 causes a preload request to the prefetch module. The controller acknowledges the request in the cycle after the write and if possible stops any outstanding flash access and stalls any CPU load from the cache or Flash.

When it has finished or stalled the previous transaction, it initiates a flash read to fetch the instructions or data requested using the address in CHETAG.LTAG. After the programmed number of Wait states as defined by CHECON.PFMWS, the controller updates the data array with the values read from flash. On the update it sets CHETAG.LVALID = 1. The LRU state of the line is not affected.

Once the controller finishes updating the cache, it allows CPU requests to complete. If this request misses the cache, the controller initiates a flash read which incurs the full flash access time.

9.3.3 ADDRESS MASK

Cache lines 10 and 11 allow masking of the CPU address and tag address to force a match on corresponding bits. The CHEMSK.LMASK field is set up to compliment the interrupt vector spacing field in the CPU. This feature allows boot code to lock the first four instruction of a vector in the cache. If all vectors contain identical instructions in their first four locations, then setting the CHEMSK.LMASK to match the vector spacing and the LTAG to match the vector base address causes all the vector addresses to hit the cache. The prefetch module responds with zero Wait states and immediately initiates a fetch of the next set of four instruction for the requesting vector if prefetch is enabled.

Using CHEMSK.LMASK is restricted to aligned address ranges. Its size allows for a max range of 32KB and a minimum spacing of 32B. Using the two lines, in conjunction provides the ability to have different ranges and different spacing.

Setting up the address mask such that more than one line will match an address causes undefined results. Therefore, it is highly recommended to set up masking before entering cacheable code.

EXAMPLE 9-3: EXAMPLE CODE: DUPLICATION OF CODE USING MASK REGISTERS

#define INT_LINE_NUM 10
CHEACC = (1<<31) | INT_LINE_NUM;
tmp = (unsigned long)intbase;
ltagboot = (tmp & 0x00c00000) ? 0 : 1;
CHETAG = (ltagboot<<31) | (tmp & 0x0007fff0) | 6; // locked and invalid
CHEMSK = 0xe0; // first 4 instructions of intbase() replicated 8 times on 32-byte boundaries</pre>

9.3.4 PREDICTIVE PREFETCH BEHAVIOR

When configured for predictive prefetch on cacheable addresses, the module predicts the next line address and returns it into the pseudo LRU line of the cache. If enabled, the prefetch function starts predicting based on the first CPU instruction fetch. When the first line is placed in the cache, the module simply increments the address to the next 16-byte aligned address and starts a flash access. When running linear code (i.e. no jumps), the flash returns the next set of instructions into the prefetch buffer on or before all instructions can be executed from the previous line.

If at any time during a predicted flash access, a new CPU address does not match the predicted one, the flash access will be changed to the correct address. This behavior does not cause the CPU access to take any longer than without prediction.

If an access that misses the cache hits the prefetch buffer, the instructions are placed in the pseudo LRU line along with its address tag. The pseudo LRU value is marked as the most recently used line and other lines are updated accordingly. If an access misses both the cache and the prefetch buffer, the access passes to the flash and those returning instructions are placed in the pseudo LRU line.

When configured for predictive prefetch on noncacheable addresses, the controller only uses the prefetch buffer. The LRU cache line is not updated for hits or fills so the cache remains intact. For linear code, enabling predictive prefetch for non-cacheable addresses allows the CPU to fetch instructions in zero Wait states.

It is not useful to use non-cacheable predictive prefetching when accesses to the flash are set for zero Wait states. The controller holds prefetched instructions on the output of the flash for up to 3 clock cycles (while the CPU is fetching from the buffer). This consumes more power without any benefit for zero Wait state flash accesses.

Predictive data prefetching is not supported. However, a data access in the middle of a predictive instruction fetch causes the prefetch controller to stop the flash access for the instruction fetch and to start the data load from flash. The predictive prefetch does not resume, but instead waits for another instruction fetch. At which time, it either fills the buffer because of a miss, or starts a prefetch because of a hit.

9.3.5 COHERENCY SUPPORT

It is not possible to execute out of cache while programming the flash memory. The flash controller stalls the cache during the programming sequence. Therefore, user code that initiates a programming sequence must not be located in a cacheable address region.

If CHECON.CHECOH = 1, then coherency is strictly supported by invalidating, unlocking, and clearing masks for all lines whenever the Flash Program Memory is written or programmed.

If CHECON.CHECOH = 0, then only lines that are not locked are forced invalid. Lines that are locked are retained.

9.4 Prefetch Module Interrupts and Exceptions

The prefetch module does not generate any interrupts.

Exceptions can occur if cache lines are marked as valid manually by writing to individual CHETAG registers then executing code that hits one of these lines containing invalid instructions. Also manually placing data into an un-locked cache line may cause a coherency problem from an eviction due to a cache miss in the middle of the loading algorithm.

9.4.1 I/O PIN CONFIGURATION

The prefetch module does not use any external pins.

PIC32MX3XX/4XX

NOTES:

10.0 DIRECT MEMORY ACCESS (DMA) CONTROLLER

Note:	This data sheet summarizes the features of						
	the PIC32MX3XX/4XX family of devices. It						
	is not intended to be a comprehensive refer-						
	ence source. Refer to the "PIC32MX Family						
	Reference Manual" (DS61132) for a						
	detailed description of this peripheral.						

The PIC32MX Direct Memory Access (DMA) controller is a bus master module useful for data transfers between different devices without the CPU intervention. The source and destination of a DMA transfer can be any of the memory mapped modules existent in the PIC32MX (such as Peripheral Bus (PBUS) devices: SPI, UART, I²CTM, etc.) or memory itself.

Following are some of the key features of the DMA controller module:

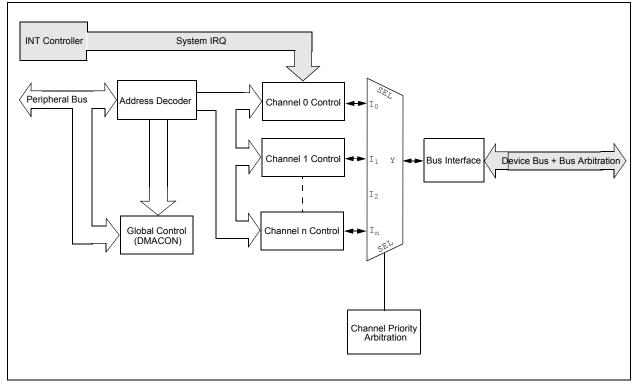

- Four Identical Channels, each featuring:
 - Auto-Increment Source and Destination Address registers
 - Source and Destination Pointers
- Automatic Word-Size Detection:
 - Transfer granularity down to byte level
 - Bytes need not be word-aligned at source and destination
- Fixed Priority Channel Arbitration
- Flexible DMA Channel Operating modes:
 - Manual (software) or automatic (interrupt) DMA requests
 - One-Shot or Auto-Repeat Block Transfer modes
 - Channel-to-channel chaining

- Flexible DMA Requests:
 - A DMA request can be selected from any of the peripheral interrupt sources
 - Each channel can select any (appropriate) observable interrupt as its DMA request source
 - A DMA transfer abort can be selected from any of the peripheral interrupt sources
 - Pattern (data) match transfer termination
- Multiple DMA Channel Status Interrupts:
 - DMA channel block transfer complete
 - Source empty or half empty
 - Destination full or half-full
 - DMA transfer aborted due to an external event
 - Invalid DMA address generated
- DMA Debug Support Features:
 - Most recent address accessed by a DMA channel
 - Most recent DMA channel to transfer data
- CRC Generation Module:
 - CRC module can be assigned to any of the available channels
 - CRC module is highly configurable

10.2 DMA Controller Operation

A DMA channel will transfer data from a source to a destination without CPU intervention.

DMA controller configuration resources:

- The DMA Controller and the corresponding DMA channel have to be enabled using the ON (DMACON<15>) and the CHEN (DCHxCON<7>) bits.
- The source and destination of the transfer are programmable using the DCHxSSA and DCHxDSA registers respectively.
- The source and destination are further independently configurable using the DCHxSSIZ and DCHxDSIZ registers.
- A DMA transfer can be initiated in one of two ways:
 - Software can initiate a transfer by setting the channel CFORCE (DCHxECON<7>) bit.
 - An interrupt event occurs that matches the CHSIRQ (DCHxECON<15:8>) interrupt and SIRQEN = 1 (DCHxECON<4>). The user can select any interrupt on the device to start a DMA transfer.

Note:	BMX arbitration mode 2 (rotating priority) is							
	recommended when a system may							
	experience heavy bus load.							

- At each event requiring a DMA transfer, a number of bytes specified by the cell size (DCHxCSIZ) will be transferred (one or more transactions will occur).
- The channel keeps track of the number of bytes transferred from the source to destination, using Source and Destination Pointers (DCHxSPTR and DCHxDPTR).
- The Source and Destination Pointers are readonly and are updated after every transaction.
- Interrupts are generated when the Source or Destination pointer is half of the source or destination size (DCHxSSIZ/2 or DCHxDSIZ/2), or when the source or destination counter equals the size of the source or destination. These interrupts are CHSHIF, CHDHIF and CHSDIF, CHDDIF, respectively.

- · The Source and Destination Pointers are reset:
 - On any device Reset.
 - When the DMA is turned off (ON bit (DMACON<15>) is '0').
- Note: Always wait for the channels to complete the current transactions (or abort first and make sure the transfers were successfully aborted) before switching the DMA controller OFF.
 - A block transfer completes (regardless of the state of CHAEN (DCHxCON<4>)).
 - A pattern match terminates a transfer (regardless of the state of auto-enable CHAEN (DCHxCON<4>)).
 - CABORT (DCHxECON<6>) flag is written.
- Note: If the DMA channel is suspended in the middle of a transfer (If CHEN (DCHxCON)<7> = 0) or if the DMA controller is suspended in the middle of a transfer (If SUSPEND (DMACON)<12> = 1) and a CABORT is issued, the Source, Destination and Cell pointers are not Reset.
- If the channel source address (DCHxSSA) is updated, the Source Pointer (DCHxSPTR) will be reset.
- Similarly, updates to the Destination Address (DCHxDSA) will cause the Destination Pointer (DCHxDPTR) to be reset.
- Normally, the DMA channel remains enabled until the DMA channel has completed a block transfer unless the auto-enable feature is turned on (i.e., CHAEN = 1).
- When the channel is disabled, further transfers will be prohibited until the channel is re-enabled (CHEN is set to '1').
- A DMA transfer request will be stopped/aborted by:
 - Writing the CABORT bit (DCHxECON<6>).
 - Pattern match occurs if pattern match is enabled PATEN = 1 (DCHxECON<5>), provided that channel CHAEN is not set.
 - Interrupt event occurs on the device that matches the CHAIRQ (DCHxECON<23:16>) interrupt if enabled by AIRQEN (DCHxECON<3>).
 - An address error is detected.
 - A block transfer completes provided that Channel Auto-Enable mode (CHAEN) is not set.
- When a channel abort interrupt occurs, the Channel Abort Interrupt Flag, CHTAIF, (DCHxINT<1>) is set. This allows the user to detect and recover from an aborted DMA transfer. When a transfer is aborted, any transaction currently underway will be completed.

10.2.1 DMA CONTROLLER TERMINOLOGY

Event: Any system event that can initiate or abort a DMA transfer.

Transaction: A single-word transfer (up to 4 bytes), comprised of read and write operations.

Cell Transfer: The number of bytes transferred when a DMA channel has a transfer initiated before waiting for another event (given by the DCHCSIZ register). A cell transfer comprises one or more transactions.

Block Transfer: Defined as the number of bytes transferred when a channel is enabled. The number of bytes is the larger of either DCHxSSIZ or DCHxDSIZ. A block transfer comprises one or more cell transfers.

10.3 Basic Transfer Mode

Basic Transfer mode transfer features:

- The transfer size is limited to a maximum of 256 bytes transferred per channel.
- The Source and Destination Pointers wrap around based on the selected source and destination size.
- A block transfer is complete when the block size bytes have been transferred. The block size is the larger of source and destination sizes:
 - blockSize = max (DCHxSSIZ, DCHxDSIZ).
- A DMA event will transfer cell size (DCHxCSIZ) bytes from source to destination. However, if DCHxCSIZ is greater than the block size, then just block size bytes will be transferred.

10.3.1 BASIC TRANSFER MODE CONFIGURATION

Microchip recommends taking the following steps to configure a DMA transfer:

- Disable the DMA channel interrupts in the INT controller.
- Clear any existing channel interrupt flags in the INT controller.
- Enable the DMA controller (if not already enabled) in DMACON register.
- Set Channel Control register: Priority, Auto-Enable mode, etc., in DCHxCON. (Don't enable the channel yet!)
- Set the channel event control: clear/set the events starting and aborting the transfer. If needed, also set the pattern match enable in DCHxECON.
- If using a pattern match, set the pattern in the DCHxDAT register.
- Set the transfer source and destination physical addresses (DCHxSSA and DCHxDSA registers).
- Set the source and destination sizes (DCHxSSIZ, DCHxDSIZ registers).
- Set the cell transfer size (DCHxCSIZ).
- Clear any existing event flag in the DCHxINT register.
- · If using interrupts:
 - Set the conditions that will generate an interrupt in the DCHxINT register (at least error interrupt enable and abort interrupt enable, usually block complete interrupt).
 - Set the DMA channel interrupt priority and subpriority in the INT controller.
 - Enable the DMA channel interrupt in the INT controller.
- Enable the selected DMA channel with CHEN (DCHxCON<7>).
- If not using system events to start the DMA transfer use CFORCE (DCHxECON<7>) to start transfer.
- Until the DMA transfer is complete you can do some other processing.
- If transfer complete interrupts (cell complete, block complete, etc.) are enabled, a notification will be presented in the ISR that the DMA transfer completed.
- Otherwise, the DMA channel can be polled to see if the transfer is completed using, for example, CHBCIF (DCHxINT<3>).

Refer to Example 10-1.

```
EXAMPLE 10-1:
                 CONFIGURING THE DMA FOR BASIC TRANSFER MODE OPERATION
The following code example illustrates the DMA channel 0 configuration for a basic transfer.
 * /
       IEC1CLR=0x00010000;
                                    // disable DMA channel 0 interrupts
       IFS1CLR=0x00010000;
                                    // clear existing DMA channel 0 interrupt flag
       DMACONSET=0x00008000;
                                    // enable the DMA controller
       DCH0CON=0x3;
                                     // channel off, pri 3, no chaining
       CHOECON=0;
                                     // no start or stop irq's, no pattern match
                                     // program the transfer
       DCH0SSA=0x1d010000;
                                     // transfer source physical address
       DCH0DSA=0x1d020000;
                                     // transfer destination physical address
       DCHOSSIZ=0;
                                     // source size 256 bytes
       DCH0DSIZ=0;
                                     // destination size 256 bytes
       DCH0CSIZ=0;
                                     // 256 bytes transferred per event
       DCH0INTCLR=0x00ff00ff;
                                    // clear existing events, disable all interrupts
       DCH0CONSET=0x80:
                                     // turn channel on
                                     // initiate a transfer
       DCH0ECONSET=0x0000080;
                                     // set CFORCE to 1
       // do something else
       // poll to see that the transfer was done
       while(TRUE)
       {
              register int pollCnt; // use a poll counter.
                                     // polling continuously the DMA controller in a tight
                                     // loop would affect the performance of the DMA transfer
              int dmaFlags=DCH0INT;
              if( (dmaFlags&0xb)
               {
                                     // one of CHERIF (DCHxINT<0>), CHTAIF (DCHxINT<1>)
                                     // or CHBCIF (DCHxINT<3>) flags set
                                    // transfer completed
                     break:
              }
              pollCnt=100;
                                    // use an adjusted value here
              while(pollCnt--);
                                    // wait before reading again the DMA controller
       }
       // check the transfer completion result
```

10.4 Pattern Match Termination

The Pattern Match mode is enabled by setting the PATEN bit (DCHxECON<5>).

This feature is useful in applications where a variable data size is required and eases the setup of the DMA channel. A good usage is for transferring ASCII command strings from an UART, <CR> ended. This is also useful for implementing string copy routines with DMA support.

Pattern Match mode features:

- Allows the user to end a transfer if a byte of data written during a transaction matches a specific pattern.
- A pattern match is treated the same way as a block transfer complete, where the CHBCIF (DCHxINT<3>) bit is set and the CHEN (DCHxCON<7>) bit is cleared provided auto-enable CHAEN = 0 (DCHxCON<4>).
- The pattern is stored in the DCHxDAT register.
- If any byte in the source matches DCHxDAT, a pattern match is detected.

10.4.1 PATTERN MATCH MODE CONFIGURATION

The Pattern Match mode is an option for use when performing DMA transfers in basic DMA configuration. Therefore, the steps needed in Pattern Match mode are identical to those used in basic DMA configuration. An extra step is needed to store the desired pattern in DCHxDAT register.

The following steps are recommended to be taken to configure a DMA transfer in Pattern Match mode:

- Disable the DMA channel interrupts in the INT controller.
- Clear any existing channel interrupt flags in the INT controller.
- Enable the DMA controller (if not already enabled) in DMACON register.
- Set Channel Control register: Priority, Auto-Enable mode, etc., in DCHxCON. Don't enable the channel yet.
- Set the channel event control: clear/set the events starting and aborting the transfer. Set the pattern match enable PATEN in DCHxECON.
- Set the pattern in the DCHxDAT register.
- Set the transfer source and destination physical addresses (DCHxSSA and DCHxDSA registers).
- Set the source and destination sizes (DCHxSSIZ, DCHxDSIZ registers).
- Set the cell transfer size (DCHxCSIZ).
- Clear any existing event flag in DCHxINT register.

- If using interrupts:
 - Set the conditions that will generate an interrupt in the DCHxINT register (at least error interrupt enable and abort interrupt enable, usually block complete interrupt).
 - Set the DMA channel interrupt priority and subpriority in the INT controller.
 - Enable the DMA channel interrupt in the INT controller.
- Enable the selected DMA channel with CHEN (DCHxCON<7>).
- If not using system events to start the DMA transfer use CFORCE (DCHxECON<7>) to start transfer.
- Until the DMA transfer is complete, you can do some other processing.
- If you enabled transfer complete interrupts (cell complete, block complete, etc) you'll be notified in the ISR that the DMA transfer completed.
- Otherwise, you can poll the DMA channel to see if the transfer is completed using, for example, CHBCIF (DCHxINT<3>).

Refer to Example 10-2.

CONFIGURING THE DMA FOR PATTERN MATCH OPERATION EXAMPLE 10-2:

```
/*
The following code example illustrates the DMA channel 0 configuration for data transfer with
pattern match enabled. Transfer from the UART1 a <CR> ended string, at most 256 characters long
*/
                                     // disable DMA channel 0 interrupts
      IEC1CLR=0x00010000;
      IFS1CLR=0x00010000;
                                    // clear any existing DMA channel 0 interrupt flag
       DMACONSET=0x00008000;
                                    // enable the DMA controller
                                     // channel off, priority 3, no chaining
      DCH0CON=0x03;
      DCH0ECON=(27 <<8) | 0x30;
                                    // start irq is UART1 RX, pattern match enabled
      DCH0DAT='\r';
                                     // pattern value, carriage return
                                     // program the transfer
      DCH0SSA=VirtToPhys(&U1RXREG); // transfer source physical address
      DCH0DSA=0x1d020000;
                                    // transfer destination physical address
       DCH0SSIZ=1;
                                    // source size is 1 byte
      DCH0DSIZ=0;
                                    // dst size at most 256 bytes
      DCH0CSIZ=1;
                                    // one byte per UART transfer request
      DCH0INTCLR=0x00ff00ff;
                                   // clear existing events, disable all interrupts
      DCH0INTSET=0x00090000;
                                    // enable Block Complete and error interrupts
      IPC9CLR=0x0000001f;
                                    // clear the DMA channel 0 priority and subpriority
                                    // set IPL 5, subpriority 2
       IPC9SET=0x00000016;
      IEC1SET=0x00010000;
                                    // enable DMA channel 0 interrupt
      DCH0CONSET=0x80;
                                    // turn channel on
       // wait for an UART RX interrupt to initiate a transfer
       // do something else
       // will get an interrupt when the transfer is done
       // or when an address error occurred
```

10.5 Channel Chaining Mode

The Chaining mode is enabled by setting the Chaining Enable it CHCEN bit (DCHxCON<5>) and Chaining Direction bit CHCHNS (DCHxCON<8>).

Channel chaining is an enhancement to the DMA channel operation.

A good usage is for transferring data packets from one peripheral to memory and then from memory to another peripheral. This module is also useful for implementing data acquisition in multiple buffers.

Chaining mode features:

- A channel (slave channel) can be chained to an adjacent channel (master channel). When the master channel completes a block transfer the slave channel will be enabled.
- At this point, any event on the slave channel will initiate a cell transfer. If the channel has an event pending, a cell transfer will begin immediately.
- Channels are chained in natural priority order where channel 0 has the highest priority and channel 3 the lowest. A specific channel can be enabled by an adjacent channel, either higher, or lower, in natural order, by configuring the CHCHNS (DCHxCON<8>) bit. Chaining must be enabled, CHCHN (DCHxCON<5>) = 1.
- An important feature of the DMA controller is the ability to allow events while the channel is disabled using the CHAED (DCHxCON<6>) bit. This bit is particularly useful in Chained mode where the slave channel needs to be ready to start a transfer as soon as the channel is enabled by the master channel.

10.5.1 CHAINING MODE CONFIGURATION

The Chaining mode is an option for use when performing DMA transfers. Therefore, the steps needed in Chaining mode are identical to those used in basic DMA configuration, with the following differences (refer to Section 10.3.1 "Basic Transfer Mode Configuration"):

• Two different channels have to be configured and the slave channel has to have chaining enable (CHCHN) and chaining direction (CHCHNS) set.

Refer to Example 10-3.

Channel auto-enable function is an enhancement to the DMA channel operation.

The channel auto-enable can be used to keep a channel active, even if a block transfer completes or a pattern match occurs. This prevents the user from having to re-enable the channel each time a block transfer completes. This mode is useful for applications that do repeated pattern matching.

10.6.1 AUTO-ENABLE MODE CONFIGURATION

The Auto-Enable mode is an extra option for use when performing DMA transfers. Therefore, the steps needed in Auto-Enable mode are identical to those used in basic DMA configuration, with the following differences (refer to **Section 10.3.1 "Basic Transfer Mode Configuration"**):

- The CHAEN bit has to be set before enabling the channel (setting the CHEN bit (DCHxCON<7>)).
- The channel will behave as normal except that normal termination of a transfer will not result in the channel being disabled.
- · Normal block transfer completion is defined as:
 - block transfer complete
 - pattern match detect
- · As before, the Channel Pointers will be reset.

10.6 Channel Auto-Enable Mode

The Auto-Enable mode is enabled by setting the CHAEN bit (DCHxCON<4>).

EXAMPLE 10-3: CONFIGURING THE DMA FOR CHAINING MODE OPERATION

```
/*
The following code example illustrates the DMA channel 0 configuration for data transfer with
pattern match enabled. DMA channel 0 transfer from the UART1 to a RAM buffer while DMA channel 1
transfers data from the RAM buffer to UART2. Transferred strings are at most 256 characters
long. Transfer on UART2 will start as soon as the UART1 transfer is completed.
* /
  unsigned char myBuff<256>;// transfer buffer
 TEC1CLR=0x00010000:
                            // disable DMA channel 0 interrupts
 IFS1CLR=0x00010000;
                            // clear any existing DMA channel 0 interrupt flag

 DCH1CSIZ=1;
                            // one byte per UART transfer request
 DCH0INTCLR=0x00ff00ff;
                          // DMA0: clear events, disable interrupts
 DCH1INTCLR=0x00ff00ff;
                          // DMA1: clear events, disable interrupts
 DCH1INTSET=0x00090000;
                          // DMA1: enable Block Complete and error interrupts
                            // clear the DMA channels 0 and 1 priority and
 IPC9CLR=0x00001f1f;
                            // subpriority
 IPC9SET=0x00000b16;
                            // set IPL 5, subpriority 2 for DMA channel 0
                            // set IPL 2, subpriority 3 for DMA channel 1
 IEC1SET=0x00020000;
                            // enable DMA channel 1 interrupt
 DCH0CONSET=0x80;
                            // turn channel on
 // do something else
 // the UART1 RX interrupts will initiate the DMA channel 0 transfer
 // once this transfer is complete, the DMA channel 1 will start
 // upon DMA channel 1 transfer completion will get an interrupt
 while(!intCh10curred);
                          // poll DMA channel 1 interrupt
```

10.7 CRC Module Operation

The DMA module has one integrated CRC generation module shared by all channels. The CRC module is a highly configurable, 16-bit CRC generator. The CRC module can be assigned to any available DMA channel by setting the CRCCH bits (DCRCCON<1:0>) appropriately. The CRC is enabled by setting the CRCEN bit (DCRCCON<7>).

The CRC generator will take 1 system clock to process each byte of data read from the source. This implies that if 32 bits of data are read from the source, the CRC generation will take 4 system clocks to process the data.

The CRC module modifies the behavior of the DMA channel associated with the CRC module. The two operating modes for a DMA channel associated with the CRC module are:

- Background Mode: CRC is calculated in the background, with normal DMA behavior maintained.
- Append Mode: Data read from the source is not written to the destination, but the CRC data is accumulated in the CRC data register. The accumulated CRC is written to the destination address when a block transfer completes.

CRC Configurable resources:

- The terms of the polynomial can be programmed using the DCRCXOR<15:0> bits. Considering the CRC polynomial: $x^{16} + x^{12} + x^5 + 1$, 17 bits are needed to define this polynomial. However, the value to be written to the DCRCXOR register will be 0b0001 0000 0010 0000, i.e., 0x1020.
- Note: The LSb and MSb do not have to be specified, they are always set. The actual value used for the polynomial generator will be 0x11021.
- The length of the polynomial generator can be programmed using the PLEN (DCRCCON<11:8>) bits. For the above polynomial, the size will be 16. The PLEN will be programmed with length -1, i.e., 0x0F.
- The CRC module can be assigned to any available DMA channel by setting the CRCCH bits (DCRCCON<2:0>) appropriately.
- The CRC is enabled by setting the CRCEN bit (DCRCCON<7>).
- The CRC generator can be seeded by writing to the DCRCDATA register before enabling the channel that will use the CRC module.
- The CRC can be read as it progresses by reading the DCRCDATA register at any time during the CRC generation.
- Data Order: As data is read from the source register, the data is fed into the CRC generator MSB first.

10.8 CRC Background Mode

The CRC Background mode is enabled by clearing CRCAPP (DCRCCON<6>).

In this mode, the behavior of the DMA channel is maintained with data read from the channel source being passed to the CRC module and then written back to the destination.

In the Background mode, the calculated CRC is left in the DCRCDATA register at the end of the block transfer.

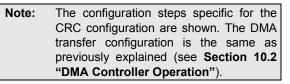

This mode can be used to calculate a CRC as data is moved from source to destination. A good example of where this can be used is to calculate a CRC as data is transmitted to or received from the UART module. When the data transfer is complete the user can read the calculated CRC and either append it to the transmitted data or verify the received CRC data.

10.8.1 CRC BACKGROUND MODE CONFIGURATION

Microchip recommends taking the following steps to configure a CRC calculation in Background mode:

- Seed the CRC generator by writing the initial seed to the DCRCDATA register.
- Set the polynomial generator by writing to the DCRCXOR register.
- Set the polynomial generator length by writing the PLEN (DCRCCON<11:8>).
- Attach the CRC calculation to the desired DMA channel performing the transfer by writing the CRCCH (DCRCCON<2:0>).
- Use the Background mode by clearing the CRCAPP (DCRCCON<6>) bit.
- Enable the CRC calculation by setting the CRCEN (DCRCCON<7>).
- Once the DMA transfer begins, the CRC calculation will begin as well.
- Once the DMA transfer ends, the CRC result will be available by reading the DCRCDATA register.

Refer to Example 10-4.

EXAMPLE 10-4: CRC BACKGROUND MODE OPERATION

```
The following code example illustrates a DMA calculation using the CRC background mode. Data is
transferred from a 256 bytes Flash buffer to a RAM buffer and the CRC is calculated while the
transfer takes place. */
                                  // CRC of the flash block
 unsigned int blockCrc;
 IEC1CLR=0x00010000;
                                  // disable DMA channel 0 interrupts
 IFS1CLR=0x00010000;
                                  // clear any existing DMA channel 0 interrupt flag
 DMACONSET=0x00008000;
                                  // enable the DMA controller
                                  // seed the CRC generator
 DCRCDATA=0xffff;
                                  // Use the standard CCITT CRC 16 polynomial: X^16+X^12+X^5+1 \,
 DCRCXOR=0x1021;
                                  // CRC enabled, polynomial length 16, background mode
 DCRCCON=0x0f80:
                                  // CRC attached to the DMA channel 0.
 DCH0CON=0x03;
                                  // channel off, priority 3, no chaining
 DCH0ECON=0;
                                  // no start irqs, no match enabled
                                  // program channel transfer
                                 // transfer source physical address
 DCH0SSA=VirtToPhys(flashBuff);
 DCH0DSA=VirtToPhys(ramBuff);
                                  // transfer destination physical address
 DCH0SSIZ=0;
                                  // source size
 DCH0DSIZ=0;
                                  // dst size
                                  // 256 bytes per transfer
 DCH0CSIZ=0;
 DCH0INTCLR=0x00ff00ff;
                                  // DMA0: clear events, disable interrupts
                                  // channel 0 on
 DCH0CONSET=0x80;
                                  // initiate a transfer
 DCH0ECONSET=0x0000080;
                                  // set CFORCE to 1
 // do something else while the transfer takes place
 //\ensuremath{\left/\right.} poll to see that the transfer was done
 BOOL error=FALSE;
 while(TRUE)
 {
       register int pollCnt;
                              // don't poll in a tight loop
       int dmaFlags=DCH0INT;
       if( (dmaFlags& 0x3)
                                  // CHERIF (DCHxINT<0>) or CHTAIF (DCHxINT<1> set
       {
              error=TRUE;
                                // error or aborted...
             break;
              }
                 else if (dmaFlags&0x8)
                               // CHBCIF (DCHxINT<3>) set
              {
                                  // transfer completed normally
              break:
       }
       pollCnt=100;
                                 // use an adjusted value here
       while(pollCnt--);
                                  // wait before polling again
 }
 if(!error)
 {
                                // read the CRC of the transferred flash block
      blockCrc=DCRDATA;
 }
 else
 {
                                  // process error
 }
```

10.9 CRC Append Mode

The CRC Append mode is enabled by setting CRCAPP (DCRCCON<6>).

In this mode, the behavior of the DMA channel is changed.

Data read from the source will be fed into the CRC generation module. No data is written to the destination address in CRC Append mode until a block transfer completes or a pattern match occurs. On completion, the CRC value will be written to the address given by the Destination register (DCHxDSA).

This mode can be used for the CRC calculation of a memory buffer, without actually performing a DMA transfer to a destination.

CRC Append mode Features:

- Only the source is considered when deciding if a block transfer is complete.
- The destination address (DCHxDSA) is only used as the location to write the generated CRC to.
- The destination size (DCHxDSIZ) can have a maximum size of 4.
 - If DCHxDSIZ is greater than 4, only 4 bytes are written at the end of the transfer.
 - If DCHxDSIZ is less than 4, only DCHxDSIZ bytes of the CRC are written to the destination address.
 - The high bytes (bits 31:16) are written as 0's if more than 16 bits of the CRC are written.
 - PLEN (CRCCON<11:8>) has no effect on the number of CRC bits that will be written to the Destination register.
- No CRC written back on an abort IRQ, user abort, bus error, etc.

10.9.1 CRC APPEND MODE CONFIGURATION

Microchip recommends taking the following steps to configure a CRC calculation in Background mode:

- Seed the CRC generator by writing the initial seed to the DCRCDATA register.
- Set the polynomial generator by writing to the DCRCXOR register.
- Set the polynomial generator length by writing the PLEN (DCRCCON<11:8>).
- Attach the CRC calculation to the desired DMA channel performing the transfer by writing the CRCCH (DCRCCON<2:0>).
- Use the Append mode by setting the CRCAPP (DCRCCON<6>) bit.
- Enable the CRC calculation by setting the CRCEN (DCRCCON<7>).
- Program the DMA transfer destination with the physical address of a variable where the CRC is to be stored.
- Once the DMA transfer begins, the CRC calculation will begin as well.
- Once the DMA transfer ends, the CRC result will be deposited at the programmed DMA destination address.

Refer to Example 10-5.

Note: The configuration steps specific for the CRC configuration are shown. The DMA transfer configuration is the same as previously explained (see Section 10.2 "DMA Controller Operation").

EXAMPLE 10-5: CRC APPEND MODE OPERATION

```
/*
The following code example illustrates a DMA calculation using the CRC append mode. The CRC of a
200 bytes flash buffer is calculated without performing any data transfer. As soon as the CRC
calculation is completed the CRC value of the flash buffer is available in a local variable for
further use. */
unsigned int blockCrc;
                                 // CRC of the flash block
 IEC1CLR=0x00010000;
                                 // disable DMA channel 0 interrupts
 IFS1CLR=0x00010000;
                                 // clear any existing DMA channel 0 interrupt flag
 DMACONSET=0x00008000;
                                 // enable the DMA controller
 DCRCDATA=0xffff;
                                  // seed the CRC generator
 DCRCXOR=0x1021;
                                 // Use the standard CCITT CRC 16 polynomial: X^16+X^12+X^5+1
 DCRCCON=0x0fc0;
                                  // CRC enabled, polynomial length 16, append mode
                                  // CRC attached to the DMA channel 0.
                                  // channel off, priority 3, no chaining
 DCH0CON=0x03;
 DCHOECON=0;
                                  // no start irqs, no match enabled
                                  // program channel transfer
 DCH0SSA=VirtToPhys(flashBuff);
                                 // transfer source physical address
 DCH0DSA=VirtToPhys(&blockCrc); // transfer destination physical address
 DCH0SSIZ=200;
                                  // source size
                                 // dst size
 DCH0DST7=200;
 DCH0CSIZ=200;
                                 // 200 bytes per transfer
 DCH0INTCLR=0x00ff00ff;
                                 // DMA0: clear events, disable interrupts
 DCH1INTCLR=0x00ff00ff;
                                 // DMA1: clear events, disable interrupts
 DCH0CONSET=0x80;
                                  // channel 0 on
                                  // initiate a transfer
 DCH0ECONSET=0x0000080;
                                  // set CFORCE to 1
 // do something else while the CRC calculation takes place
 // poll to see that the transfer was done
 BOOL error=FALSE;
 while (TRUE)
       register int pollCnt;
                                 // don't poll in a tight loop
      int dmaFlags=DCH0INT;
      if( (dmaFlags& 0x3)
                                 // CHERIF (DCHxINT<0>) or CHTAIF (DCHxINT<1> set
       {
                                 // error or aborted...
              error=TRUE;
              break;
              }
                     else if (dmaFlags&0x8)
                                 // CHBCIF (DCHxINT<3>) set
              {
                                 // transfer completed normally
                    break;
      pollCnt=100;
                                 // use an adjusted value here
      while(pollCnt--);
                                 // wait before polling again
 }
 if(error)
 {
                           // process error
 }
 // the block CRC is available in the blockCrc variable
```

10.10 DMA Interrupts

The DMA device has the ability to generate interrupts reflecting the events that occur during the channel's data transfer. The different kinds of DMA interrupt flags are:

- CHERIF (DCHxINT<0>): Channel Error interrupts, enabled using CHERIE (DCHxINT<16>).
- CHTAIF (DCHxINT<1>): Channel Abort interrupts, enabled using CHTAIE (DCHxINT<17>).
- CHBCIF (DCHxINT<3>): Channel Block complete interrupts, enabled using CHBCIE (DCHxINT<19>).
- CHCCIF (DCHxINT<2>): Channel Cell complete interrupts, enabled using CHCCIE (DCHxINT<18>).
- CHSDIF (DCHxINT<7>): Channel Source pointer reached the end of the source, enabled by CHSDIE (DCHxINT<23>).
- CHSHIF (DCHxINT<6>): Channel Source pointer reached midpoint of the source, enabled by CHSHIE (DCHxINT<22>).
- CHDDIF (DCHxINT<5>): Channel Destination Pointer reached the end of the destination, enabled by CHDDIE (DCHxINT<21>)
- CHDHIF (DCHxINT<4>): Channel Destination Pointer reached midpoint of the destination, enabled by CHDHIE (DCHxINT<20>).

All the interrupts belonging to a DMA channel map to the corresponding channel interrupt vector.

The corresponding interrupt flags are:

- DMA0IF (IFS1<16>)
- DMA1IF (IFS1<17>)
- DMA2IF (IFS1<18>)
- DMA3IF (IFS1<19>)

All these interrupt flags must be cleared in software.

A DMA channel is enabled as a source of interrupts via the respective DMA interrupt enable bits:

- DMA0IE (IEC1<16>)
- DMA1IE (IEC1<17>)
- DMA2IE (IEC1<18>)
- DMA3IE (IEC1<19>)

The interrupt priority level bits and interrupt subpriority level bits must be also be configured:

- DMA0IP<2:0> (IPC9<4:2>), DMA0IS<1:0> (IPC9<1:0>).
- DMA1IP<2:0> (IPC9<12:10>), DMA1IS<1:0> (IPC9<9:8>).
- DMA2IP<2:0> (IPC9<20:18>), DMA2IS<1:0> (IPC9<17:16>).
- DMA3IP<2:0> (IPC9<28:26>), DMA3IS<1:0> (IPC9<25:24>).

In addition to enabling the DMA interrupts, Interrupt Service Routines (ISRs) are required for each different interrupt vector used. See Example 10-6 and Example 10-7.

Note: It is the user's responsibility to clear the corresponding interrupt flag bit before returning from an ISR.

EXAMPLE 10-6: DMA INITIALIZATION WITH INTERRUPTS

```
/*
The following code example illustrates a DMA channel 0 interrupt configuration.
When the DMA channel 0 interrupt is generated, the CPU will jump to the vector assigned to DMA0
interrupt.
*/
      IEC1CLR=0x00010000;
                                  // disable DMA channel 0 interrupts
      IFS1CLR=0x00010000;
                                  // clear any existing DMA channel 0 interrupt flag
      DMACONSET=0x00008000;
                                  // enable the DMA controller
                                  // channel off, priority 3, no chaining
      DCH0CON=0x03;
                                  // no start or stop irq's, no pattern match
       DCH0ECON=0;
                                  // program the transfer
                                  // transfer source physical address
      DCH0SSA=0x1d010000;
                                  // transfer destination physical address
      DCH0DSA=0x1d020000:
      DCH0SSIZ=0;
                                  // source size 256 bytes
      DCH0DSIZ=0;
                                  // destination size 256 bytes
      DCH0CSIZ=0;
                                  // 256 bytes transferred pe event
      DCH0INTCLR=0x00ff00ff; // clear existing events, disable all interrupts
       DCH0INTSET=0x00090000;
                                  // enable Block Complete and error interrupts
                                  // clear the DMA channel 0 priority and subpriority
      IPC9CLR=0x000001f;
                                  // set IPL 5, subpriority 2
      IPC9SET=0x00000016;
                                  // enable DMA channel 0 interrupt
      IEC1SET=0x00010000;
      DCH0CONSET=0x80;
                                  // turn channel on
                                  // initiate a transfer
      DCH0ECONSET=0x00000080;
                                  // set CFORCE to 1
       // do something else
       // will get an interrupt when the block transfer is done
       // or when error occurred
```

EXAMPLE 10-7: DMA CHANNEL 0 ISR

```
The following code example demonstrates a simple Interrupt Service Routine for DMA channel 0
interrupts. The user's code at this vector should perform any application specific operations
and must clear the DMAO interrupt flags before exiting.
* /
void ISR( DMA0 VECTOR, IPL5) DMA0Interrupt(void)
       int dmaFlags=DCH0INT&0xff;
                                      // read the interrupt flags
       // perform application specific operations in response to any interrupt flag set
       DCH0INTCLR=0x000000ff;
                                      // clear the DMA channel interrupt flags
       IFS1CLR = 0 \times 00010000;
                                      // Be sure to clear the DMA0 interrupt flags
                                       // before exiting the service routine.
               The DMA ISR code example shows MPLAB<sup>®</sup> C32 C compiler specific syntax. Refer to your
       Note:
               compiler manual regarding support for ISRs.
```

10.11 I/O Pin Control

The DMA controller module does not use any I/O pins.

11.0 USB ON-THE-GO

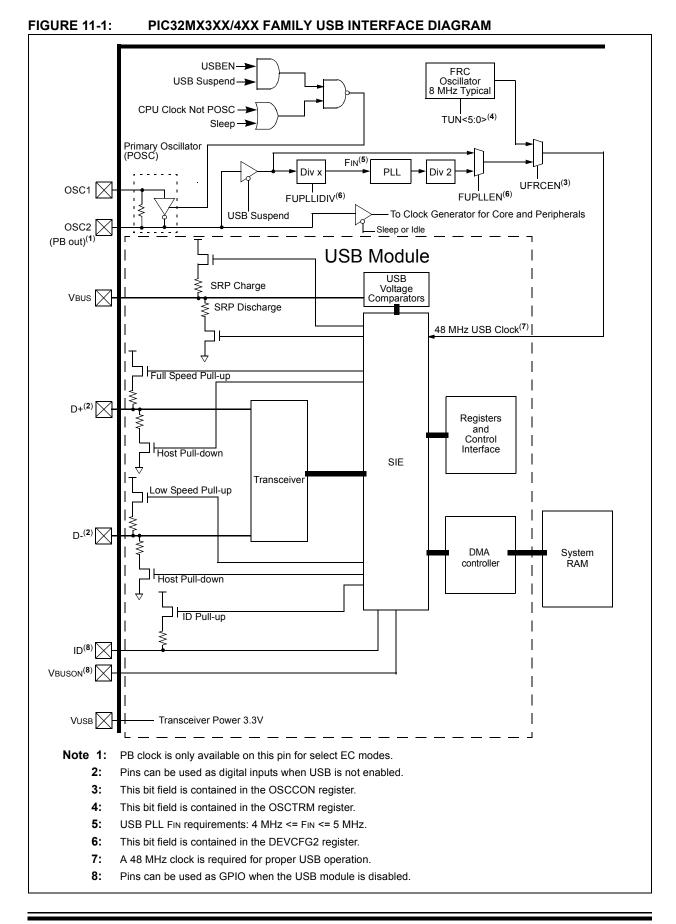

Note:	This data sheet summarizes the features of
	the PIC32MX3XX/4XX family of devices. It
	is not intended to be a comprehensive refer-
	ence source. Refer to the "PIC32MX Family
	Reference Manual" (DS61132) for a
	detailed description of this peripheral.

The Universal Serial Bus (USB) module contains analog and digital components to provide a USB 2.0 fullspeed and low-speed embedded host, full-speed device, or OTG implementation with a minimum of external components. This module in Host mode is intended for use as an embedded host and therefore does not implement a UHCI or OHCI controller.

The USB module consists of the clock generator, the USB voltage comparators, the transceiver, the Serial Interface Engine (SIE), a dedicated USB DMA controller, pull-up and pull-down resistors, and the register interface. A block diagram of the PIC32MX USB OTG module is presented in Figure 11-1.

The clock generator provides the 48 MHz clock required for USB full-speed and low-speed communication. The voltage comparators monitor the voltage on the VBUS pin to determine the state of the bus. The transceiver provides the analog translation between the USB bus and the digital logic. The SIE is a state machine that transfers data to and from the endpoint buffers, and generates the hardware protocol for data transfers. The USB DMA controller transfers data between the data buffers in RAM and the SIE. The integrated pull-up and pull-down resistors eliminate the need for external signaling components. The register interface allows the CPU to configure and communicate with the module. The PIC32MX USB module includes the following features:

- · USB Full-Speed Support for Host and Device
- Low-Speed Host Support
- USB On-The-Go (OTG) Support
- Integrated Signaling Resistors
- Integrated Analog Comparators for VBUS Monitoring
- Integrated USB Transceiver
- Transaction Handshaking Performed by Hardware
- Endpoint Buffering Anywhere in System RAM
- Integrated DMA Controller to Access System RAM and Flash
- Note: IMPORTANT: The implementation and use of the USB specifications, as well as other third-party specifications or technologies, may require licensing; including, but not limited to, USB Implementers Forum, Inc. (also referred to as USB-IF). The user is fully responsible for investigating and satisfying any applicable licensing obligations.

11.1 Control Registers

The USB module includes the following Special Function Registers (SFRs):

- U1OTGIR: USB OTG Interrupt Flag Register
- U1OTGIE: USB OTG Interrupt Enable Register
- U1OTGSTAT: USB Comparator and Pin Status Register
- U1OTGCON: USB Resistor and Pin Control Register
- U1PWRC: USB Power Control Register
- U1IR: USB Pending Interrupt Register
- U1IE: USB Interrupt Enable Register
- U1EIR: USB Pending Error Interrupt Register
- U1EIE: USB Interrupt Enable Register
- U1STAT: USB Status FIFO Register
- U1CON: USB Module Control Register
- U1ADDR: USB Address Register
- U1FRMH and U1FRML: USB Frame Count Registers
- U1TOK: USB Host Control Register
- U1SOF: USB SOF Counter Register
- U1BDTP1, U1BDTP2, and U1BDTP3: USB Buffer Descriptor Table Pointer Register
- U1CNFG1: USB Debug and Idle Register
- U1EP0-U1EP15: USB Endpoint Control Registers

11.2 U1OTGIR Register

U1OTGIR (Register 11-1) records changes on the ID, data and VBUS pins, enabling software to determine which event caused an interrupt. The interrupt bits are cleared by writing a '1' to the corresponding interrupt.

11.3 U1OTGIE Register

U1OTGIE (Register 11-2) enables the corresponding interrupt Status bits defined in the U1OTGIR register to generate an interrupt.

11.4 U1OTGSTAT Register

U1OTGSTAT (Register 11-3) provides access to the status of the VBUS voltage comparators and the debounced status of the ID pin.

11.5 U1OTGCON Register

U1OTGCON (Register 11-4) controls the operation of the VBUS pin, and the pull-up and pull-down resistors.

11.6 U1PWRC Register

U1PWRC (Register 11-5) controls the power-saving modes, as well as the module enable/disable control.

11.7 U1IR Register

U1IR (Register 11-6) contains information on pending interrupts. Once an interrupt bit is set, it can be cleared by writing a '1' to the corresponding bit.

11.8 U1IE Register

U1IE (Register 11-7) values provide gating of the various interrupt signals onto the USB interrupt signal. These values do not interact with the USB module. Setting any of these bits enables the corresponding interrupt source in the U1IR register.

11.9 U1EIR Register

U1EIR (Register 11-8) contains information on pending error interrupt values. Once an interrupt bit is set, it can be cleared by writing a '1' to the corresponding bit.

11.10 U1EIE Register

U1EIE (Register 11-9) values provide gating of the various interrupt signals onto the USB interrupt signal. These values do not interact with the USB module. Setting any of these bits enables the respective interrupt source in the U1EIR register if UERR is also set in the U1IE register.

11.11 U1STAT Register

U1STAT (Register 11-10) is a 16-deep First In, First Out (FIFO) register. It is read-only by the CPU and read/write by the USB module. U1STAT is only valid when the U1IR<TRNIF> bit is set.

11.12 U1CON Register

U1CON (Register 11-11) provides miscellaneous control and information about the module.

11.13 U1ADDR Register

U1ADDR (Register 11-12) is a read/write register from the CPU side and read-only from the USB module side. Although the register values affect the settings of the USB module, the content of the registers does not change during access.

In Device mode, this address defines the USB device address as assigned by the host during the SETUP phase. The firmware writes the address in response to the SETUP request. The address is automatically reset when a USB bus Reset is detected. In Host mode, the module transmits the address provided in this register with the corresponding token packet. This allows the USB module to uniquely address the connected device.

11.14 U1FRMH and U1FRML Registers

U1FRMH and U1FRML (Register 11-13 and Register 11-14) are read-only registers. The frame number is formed by concatenating the two 8-bit registers. The high-order byte is in the U1FRMH register, and the low-order byte is in U1FRML.

11.15 U1TOK Register

U1TOK (Register 11-15) is a read/write register required when the module operates as a host. It is used to specify the token type, PID<3:0> (Packet ID), and the endpoint, EP<3:0>, being addressed by the host processor. Writing to this register triggers a host transaction.

11.16 U1SOF Register

U1SOF (Register 11-16) threshold is a read/write register that contains the count bits of the Start-of-Frame (SOF) threshold value, and are used in Host mode only.

To prevent colliding a packet data with the SOF token that is sent every 1 ms, the USB module will not send any new transactions within the last U1SOF byte times. The USB module will complete any transactions that are in progress. In Host mode, the SOF interrupt occurs when this threshold is reached, not when the SOF occurs. In Device mode, the interrupt occurs when a SOF is received. Transactions started within the SOF threshold are held by the USB module until after the SOF token is sent.

11.17 U1BDTP1, U1BDTP2 and U1BDTP3

These registers (Register 11-17, Register 11-18 and Register 11-19) are read/write registers that define the upper 23 bits of the 32-bit base address of the Buffer

Descriptor Table (BDT) in the system memory. The BDT is forced to be 512 byte-aligned. This register allows relocation of the BDT in real time.

11.18 U1CNFG1 Register

U1CNFG1 (Register 11-20) is a read/write register that controls the Debug and Idle behavior of the module. The register must be preprogrammed prior to enabling the module.

11.19 U1EP0-U1EP15

These registers control the behavior of the corresponding endpoint.

11.20 Associated Registers

The following registers are not part of the USB module but are associated with module operation.

- IEC1: Interrupt Enable Control Register (Register 11-22)
- IFS1: Interrupt Flag Status Register (Register 8-5)
- DEVCFG2: Device Configuration Word 2 (Register 27-3)
- OSCCON: Oscillator Control Register (Register 4-1)

11.21 Clearing USB OTG Interrupts

Unlike other device-level interrupts, the USB OTG interrupt status flags are not freely writable in software. All USB OTG flag bits are implemented as hardwareset bits. These bits can only be cleared in software by writing a '1' to their locations. Writing a '0' to a flag bit has no effect.

Note: Throughout this section, a bit that can only be cleared by writing a '1' to its location is referred to as "Write '1' to clear bit". In register descriptions, this function is indicated by the descriptor 'K'.

REGISTER 11-11: U1CON: USB MODULE CONTROL REGISTER (CONTINUED)

- **USBEN:** USB Module Enable bit (Device mode)
 - 1 = USB module and supporting circuitry enabled
 - 0 = USB module and supporting circuitry disabled

SOFEN: SOF Enable bit (Host mode)

- 1 = SOF token sent every 1 ms
- 0 = SOF token disabled
- **Note 1:** Software is required to check this bit before issuing another token command to the U1TOK register, see Register 11-15.
 - 2: All host control logic is reset any time that the value of this bit is toggled.
 - **3:** Software must set RESUME for 10 ms if the part is a function, or for 25 ms if the part is a host, and then clear it to enable remote wake-up. In Host mode, the USB module will append a low-speed EOP to the RESUME signaling when this bit is cleared.
 - 4: Device mode.
 - 5: Host mode.

11.22 Operation

This section contains a brief overview of USB operation, followed by PIC32MX USB module implementation specifics, and module initialization requirements.

Note:	A good understanding of USB can be
	gained from documents that are available
	on the USB implementers web site. In par-
	ticular, refer to the "Universal Serial Bus
	Specification, Revision 2.0"
	(http://www.usb.org/developers/docs/).

11.23 USB 2.0 Operation Overview

USB is an asynchronous serial interface with a tiered star configuration. USB is implemented as a master/slave configuration. On a given bus, there can be multiple (up to 127) slaves (devices), but there is only one master (host).

There are three possible module modes of operation: Host, Device, and OTG Dual Role.

11.24 Modes of Operation

The following USB implementation modes are described in this overview:

- · Host mode
 - USB Standard Host mode the USB implementation that is typically used for a personal computer
 - Embedded Host mode the USB implementation that is typically used for a microcontroller
- Device mode the USB implementation that is typically used for a peripheral such as a thumbdrive, keyboard, or mouse
- OTG Dual Role mode the USB implementation in which an application may dynamically switch its role as either host or device

11.24.1 HOST MODE

The host is the master in a USB system and is responsible for identifying all devices connected to it (enumeration), initiating all transfers, allocating bus bandwidth and supplying power to any bus-powered USB devices connected directly to it.

11.24.1.1 USB Standard Host

In USB Standard Host mode, the following features and requirements are relevant:

- · Large variety of devices are supported
- · Supports all USB transfer types
- USB hubs are supported (allows connection of multiple devices simultaneously)
- Device drivers can be updated to support new devices
- Type 'A' receptacle is used for each port
- Each port must be able to deliver a minimum of 100 mA for a configured or unconfigured device, and optionally, up to 500 mA for a configured device
- Full-speed and low-speed protocols must be supported (high-speed can be supported).

Note:	This	mode	is	not	supported	by	the
	PIC3	2MX far	nily				

11.24.1.2 Embedded Host

In Embedded Host mode, the following features and requirements are relevant:

- Only supports a specific list of devices, referred to as a Targeted Peripheral List (TPL)
- Only required to support those transfer types that are required by devices in the TPL
- · USB hub support is optional
- Device drivers are not required to be updateable
- Type 'A' receptacle is used for each port
- Only those speeds required by devices in the TLP must be supported
- Each port must be able to deliver a minimum of 100 mA for a configured or unconfigured device, and optionally, up to 500 mA for a configured device

11.24.2 DEVICE MODE

USB devices accept commands and data from the host and respond to requests for data. USB devices perform peripheral functions, e.g., a mouse or other I/O, or data storage.

The following characteristics generally describe a USB device:

- · Functionality may be class- or vendor-specific
- Draws 100 mA or less from the bus before configuration
- Can draw up to 500 mA from the bus after successful negotiation with the host
- Can support low-speed, full-speed, or high-speed protocol (high-speed support requires implementation of full-speed protocol to enumerate)
- Supports control and data transfers as required for implementation

- Optionally supports Session Request Protocol (SRP)
- · Can be bus-powered or self-powered

11.24.3 OTG DUAL ROLE

The OTG dual role device supports both USB host and device functionality. OTG dual role devices use a micro-AB receptacle. This allows a micro-A or a micro-B plug to be attached. Both the micro-A and micro-B plugs have an additional pin, the ID pin, to signify which plug type was connected. The plug type connected to the receptacle, micro-A or micro-B, determines the default role of the OTG device, host or device. An OTG device will perform the role of a host when a micro-A plug is detected. When a micro-B plug is detected, the role of a USB device is performed.

When an OTG device is directly connected to another OTG device using an OTG cable (micro-A to micro-B), Host Negotiation Protocol (HNP) can be used to swap the roles of host and USB device between the two without disconnecting and reconnecting the cable. To differentiate between the two OTG devices, the term "Adevice" refers to the device connected to the micro-A plug and "B-device" refers to the device connected to the micro-B plug.

11.24.3.1 A-Device, the Default Host

In OTG dual role, operating as a host, the following features and requirements describe an A-device:

- Supports the devices on the TPL (class support is not allowed)
- Required to support those transaction types that are required by devices in the TPL
- USB hub support is optional
- Device drivers are not required to be updateable
- · A single micro-AB receptacle is used
- Full-speed protocol must be supported (highspeed and/or low-speed protocol can be supported)
- USB port must be able to deliver a minimum of 8 mA for a configured or unconfigured device, and optionally, up to 500 mA for a configured device
- Supports HNP; the host can switch roles to become a device
- · Supports at least one form of SRP
- A-device supplies VBUS power when the bus is powered, even if the roles are swapped using HNP

11.24.3.2 B-Device, the Default Device

In OTG dual role, operating as a USB device, the following features and requirements describe a B-Device:

- · Class- or vendor-specific functionality
- · Draws 8 mA or less before configuration
- · Is typically self-powered, due to low-current

requirements, but can draw up to 500 mA after successful negotiation with the host

- · A single micro-AB receptacle is used
- Must support full-speed protocol (support of lowspeed and/or high-speed protocol is optional
- Supports control transfers, and supports data transfers as they are required for implementation
- Supports both forms of SRP VBUS pulsing and data-line pulsing
- Supports HNP

B-device does not supply VBUS power, even if the roles are swapped using HNP.

Note:	Dual role devices that do not support full OTG functionality are possible using mul-
	tiple USB receptacles. However, there
	may be special requirements if those
	devices are to be made USB compliant.
	Refer to the USB implementer's forum for
	the most current details.

.

11.24.4 PHYSICAL BUS INTERFACE

11.24.4.1 Bus Speed Selection

The USB specification defines full-speed operation as 12 Mb/s and low speed operation as 1.5 Mb/s. A data line pull-up resistor is used to identify a device as full speed or low speed. For full-speed operation, the D+ line is pulled up; for low-speed operation, the D- line is pulled up.

11.24.4.2 VBUS Control

VBUS is the 5V USB power supplied by the host or a hub to operate bus-powered devices. The need for VBUS control depends on the role of the application. If VBUS power must be enabled and disabled, the control must be managed by firmware.

The following list details the VBUS requirements:

- Standard host typically supplies power to the bus at all times.
- Host may switch off VBUS to conserve power
- USB device never powers the bus VBUS pulsing may be supported as part of the SRP.
- OTG A-device supplies power to the bus, and typically turns off VBUS to conserve power.
- OTG B-device can pulse VBUS for SRP.

Note: Refer to the specific device data sheet for VBUS electrical parameters.

11.25 PIC32MX Implementation Specifics

This section details how the USB specification requirements are implemented in the PIC32MX USB module.

11.25.1 BUS SPEED

The PIC32MX USB module supports the following speeds:

- Full-speed operation as a host and a device
- Low-speed operation as a host

11.25.2 ENDPOINTS AND DESCRIPTORS

All USB endpoints are implemented as buffers in RAM. The CPU and USB module have access to the buffers. To arbitrate access to these buffers between the USB module and CPU, a semaphore flag system is used. Each endpoint can be configured for TX and/or RX, and each has an ODD and an EVEN buffer.

Use of the Buffer Descriptor Table (BDT) allows the buffers to be located anywhere in RAM, and provides status flags and control bits. The BDT contains the address of each endpoint data buffer, as well as information about each buffer (see Figure 11-2, Figure 11-3 and Figure 11-4). Each BDT entry is called a Buffer Descriptor (BD) and is 8 bytes long. All endpoints, ranging from endpoint 0 to the highest endpoint in use, must have four descriptor entries. Even if all of the buffers for an endpoint are not used, four descriptors entries are required for each endpoint.

The USB module calculates a buffer's location in RAM using the BDT. The base of the BDT is held in registers U1BDTP1 through U1BDTP3. The address of the desired buffer is found by using the endpoint number, the type (RX/TX) and the ODD/EVEN bit to index into the BDT. The address held by this entry is the address of the desired data buffer. Refer to Section 11.24.3.1 "A-Device, the Default Host".

Note:	The contents of the U1BDTP1-U1BDTP3
	registers provide the upper 23 bits of the
	32-bit address; therefore, the BTD must
	be aligned to a 512-byte boundary (see
	Figure 11-2). This address must be the
	physical (not virtual) memory address.

Each of the 16 endpoints owns two descriptor pairs: two for packets to transmit, and two for packets received. Each pair manages two buffers, an EVEN and an ODD, requiring a maximum of 64 descriptors (16 * 2 * 2).

Having EVEN and ODD buffers for each direction allows the CPU to access data in one buffer while the USB module transfers data to or from the other buffer. The USB module alternates between buffers, clearing the UOWN bit in the buffer descriptor automatically when the transaction for that buffer is complete (see **Section 11.24.3 "OTG Dual Role"**). The use of alternating buffers maximizes data throughput by allowing CPU data access in parallel with data transfer. This technique is referred to as ping-pong buffering. Figure 11-2 illustrates how the endpoints are mapped in the BDT.

11.25.2.1 Endpoint Control

Each endpoint is controlled by an Endpoint Control register, U1EPn, that configures the transfer direction, the handshake, and the stalling properties of the endpoint. The Endpoint Control register also allows support of control transfers.

11.25.2.2 Host Endpoints

Note:	In Host mode, Endpoint 0 has additional
	bits for auto-retry and hub support.

The host performs all transactions through a single endpoint (Endpoint 0). All other endpoints should be disabled and other endpoint buffers are not be used.

11.25.2.3 Device Endpoints

Endpoint 0 must be implemented for a USB device to be enumerated and controlled. Devices typically implement additional endpoints to transfer data.

11.25.3 BUFFER MANAGEMENT

The buffers are shared between the PIC32MX and the USB module, and are implemented in system memory. So, a simple semaphore mechanism is used to distinguish current ownership of the BD, and associated buffers, in memory. This semaphore mechanism is implemented by the UOWN bit in each BD.

The USB module clears the UOWN bit automatically when the transaction for that buffer is complete. When the UOWN bit is clear, the descriptor is owned by the PIC32MX – which may modify the descriptor and buffer as necessary.

Software must configure the BDT entry for the next transaction, then set the UOWN bit to return control to the USB module.

A BD is only valid if the corresponding endpoint has been enabled in the U1EPn register. The BDT is implemented in data memory, and the BDs are not modified when the USB module is reset. Initialize the BDs prior to enabling them through the U1EPn. At a minimum, the UOWN bits must be cleared prior to being enabled.

In Host mode, BDT initialization is required before the U1TOK register is written, triggering a transfer.

FIGURE 11-2: BDT ADDRESS GENERATION

 - 1 = ODD buffer
 - 0 = EVEN buffer
- bit 2:0 Manipulated by the USB module

Buffer descriptor status format, in which hardware

writes the descriptor and hands it back to software, is

shown in Figure 11-4.

11.25.3.1 Buffer Descriptor Format

The buffer descriptor is used in the following formats:

- Control
- Status.

Buffer descriptor control format, in which software writes the descriptor and hands it to hardware, is shown in Figure 11-3.

FIGURE 11-3: USB BUFFER DESCRIPTOR FORMAT: SOFTWARE -> HARDWARE

bit 57-48 BYTE_COUNT<9:0>: Byte Count bits

Byte count represents the number of bytes to be transmitted or the maximum number of bytes to be received during a transfer.

bit 39 **UOWN:** USB Own bit⁽¹⁾

- 1 = USB module owns the BD and its corresponding buffer CPU must not modify the BD or the buffer.
- CPU owns the BD and its corresponding buffer USB module ignores all other fields in the BD.
- bit 38 **DATA0/1:** Data Toggle Packet bit
 - 1 = Transmit a Data 1 packet or Check received PID = DATA1, if DTS = 1
 - 0 = Transmit a Data 0 packet or Check received PID = DATA1, if DTS = 1
- bit 37 **KEEP:** BD Keep Enable bit
 - 1 = USB will keep the BD indefinitely once UOWN is set
 - U1STAT FIFO will not be updated and TRNIF bit will not be set at the end of each transaction.
 - 0 = USB will hand back the BD once a token has been processed
- bit 36 NINC: DMA Address Increment Disable bit
 - 1 = DMA address increment disabled
 - 0 = DMA address increment enabled
- bit 35 **DTS:** Data Toggle Synchronization Enable bit⁽²⁾
 - 1 = Data Toggle Synchronization is enabled data packets with incorrect sync value will be ignored
 0 = No Data Toggle Synchronization is performed
- bit 34 BSTALL: Buffer Stall Enable bit
 - 1 = Buffer STALL enabled
 - STALL handshake issued if a token is received that would use the BD in the given location (UOWN bit remains set, BD value is unchanged).
 - Corresponding EPSTALL bit will get set on any STALL handshake.
 - 0 = Buffer STALL disabled
- bit 31-0 **BUFFER_ADDRESS:** Buffer Address bits⁽³⁾

Starting point address of the endpoint packet data buffer.

- **Note 1:** This bit can be programmed by either the CPU or the USB module, and it must be initialized by the user to the desired value prior to enabling the USB module.
 - 2: Expected value of DATA PID (DATA0/DATA1) specified in the DATA0/1 field.
 - 3: The individual buffer addresses in the BDT must be physical memory addresses.

FIGURE 11-4: USB BUFFER DESCRIPTOR FO													OR	MA	T:	HAF	RD/	VAI	RE	-> (SOF	тт	VAF	RE							
63 31					58	57									48	47							40	39	38	37	36	35	34	33	32 0
	- BYTE COUNT<9:0>											_								NWOU	DATA0/1	PID<3:0> —					_				
31																															0
												ΒL	JFFI	ER /	٩DE	DRE	SS	<31	:0>												

bit 48-56 BYTE_COUNT<9:0>: Byte Count bits

Byte count reflects the actual number of bytes received or transmitted.

bit 39 UOWN: USB Own bit⁽¹⁾

- 1 = USB module owns the BD and its corresponding buffer CPU must not modify the BD or the buffer.
- 0 = CPU owns the BD and its corresponding buffer USB module ignores all other fields in the BD.

bit 38 DATA0/1: Data Toggle Packet bit⁽²⁾

- 1 = Data 1 packet received
- 0 = Data 0 packet received

bit 37-34 PID<3:0>: Packet Identifier bits

The current token PID when a transfer completes.

The values written back are the token PID values from the USB specification: 0x1 for an OUT token, 0x9 for and IN token or 0xd for a SETUP token.

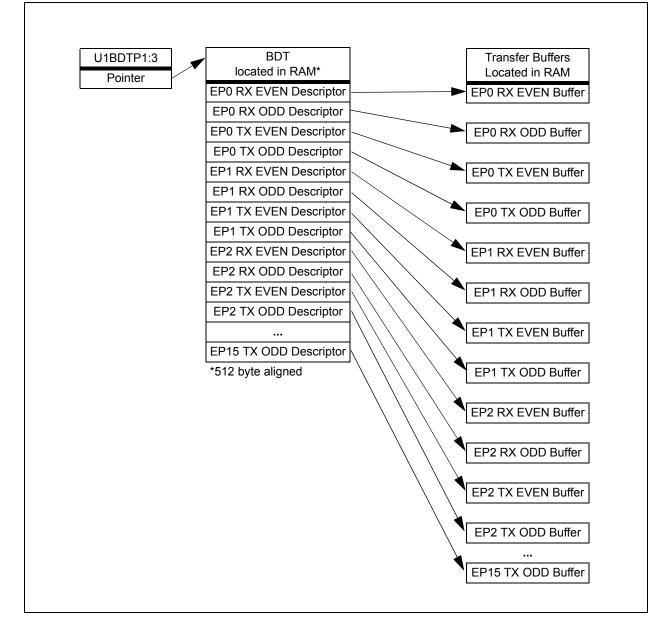

In Host mode, this field is used to report the last returned PID or a transfer status indication. The possible values returned are: 0x3 DATA0, 0xb DATA1, 0x2 ACK, 0xe STALL, 0xa NAK, 0x0 Bus Timeout, 0xf Data Error.

bit 31-0 BUFFER_ADDRESS: Buffer Address bits

Starting point address of the endpoint packet data buffer.

- **Note 1:** This bit can be programmed by either the CPU or the USB module, and it must be initialized by the user to the desired value prior to enabling the USB module.
 - 2: This bit is unchanged on an outgoing packet.

11.25.4 BUFFER DESCRIPTOR CONFIGURATION

The UOWN, DTSEN and BSTALL bits in each BDT entry control the data transfer for the associated buffer and endpoint.

Setting the DTSEN bit enables the USB module to perform data toggle synchronization. When DTS is enabled: if a packet arrives with an incorrect DTS, it will be ignored, the buffer remains unchanged, and the packet will be NAK'd (Negatively Acknowledged).

Setting the BSTALL bit causes the USB to issue a STALL handshake if a token is received by the SIE that would use the BD in this location – the corresponding EPSTALL bit is set and a STALLIF interrupt is generated. When the BSTALL bit is set, the BD is not consumed by the USB module (the UOWN bit remains set and the rest of the BD values are unchanged). If a SETUP token is sent to the stalled endpoint, the module automatically clears the corresponding BSTALL bit.

The byte count represents the total number of bytes that are transmitted or received. Valid byte counts range from 0 to 1023. For all endpoint transfers, the byte count is updated by the USB module, with the actual number of bytes transmitted or received, after the transfer is completed. If the number of bytes received exceeds the corresponding byte count value written by the firmware, the overflow bit is set and the data is truncated to fit the size of the buffer (as given in the BTD).

11.26 Hardware Interface

11.26.1 POWER SUPPLY REQUIREMENTS

Power supply requirements for USB implementation vary with the type of application, and are outlined below.

Device:

Operation as a device requires a power supply for the PIC32MX and the USB transceiver, see Figure 11-6 for an overview of USB implementation as a device.

• Embedded Host:

Operation as a host requires a power supply for the PIC32MX, the USB transceiver, and a 5V nominal supply for the USB VBUS. The power supply must be able to deliver 100 mA, or up to 500 mA, depending on the requirements of the devices in the TPL. The application dictates whether the VBUS power supply can be disabled or disconnected from the bus by the PIC32MX application. Figure 11-7 presents an overview of USB implementation as a host.

• OTG Dual Role:

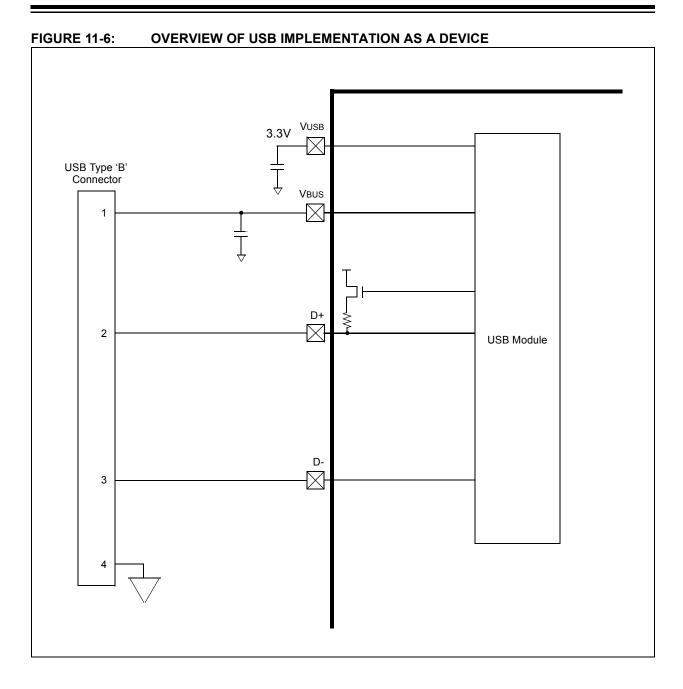

Operation as an OTG dual role requires a power supply for the PIC32MX, the USB transceiver, and a switchable 5V nominal supply for the USB VBUS. An overview of USB implementation as OTG is presented in Figure 11-8.

When acting as an A-device, power must be supplied to VBUS. The power supply must be able to deliver 8 mA, 100 mA, or up to 500 mA, depending on the requirements of the devices in the TPL.

When acting as a B-device, power must not be supplied to VBUS. VBUS pulsing can be performed by the USB module or by a capable power supply.

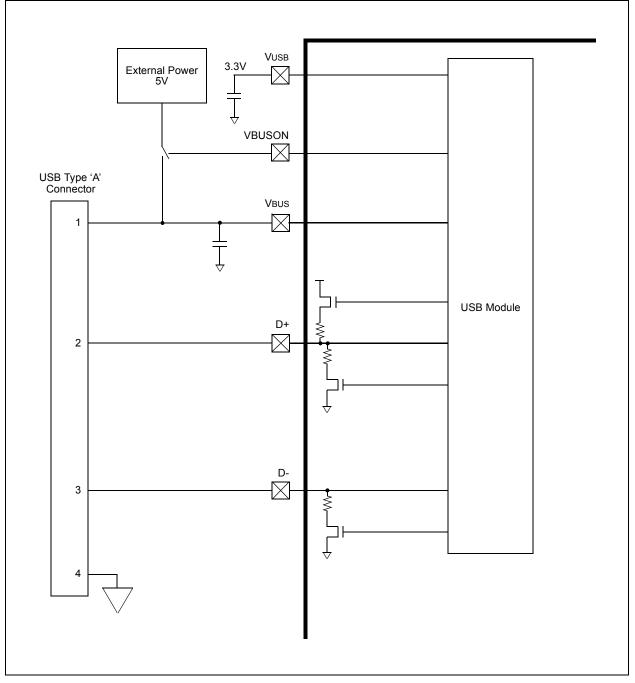

11.26.2 VBUS REGULATOR INTERFACE

The VBUSON output can be used to control an off-chip 5V VBUS regulator. The VBUSON pin is controlled by the VBUSON bit (U1OTGCON<3>). VBUSON appears in Figure 11-7 and Figure 11-8.

11.27 Module Initialization

This section describes the steps that must be taken to properly initialize the OTG USB module.

11.27.1 ENABLING THE USB HARDWARE

In order to use the USB peripheral, software must set the USBPWR bit (U1PWRC<0>) to '1'. This may be done in start-up boot sequence.

USBPWR is used to initiate the following actions:

- Start the USB clock
- · Allow the USB interrupt to be activated
- · Select USB as the owner of the necessary IO pins
- · Enable the USB transceiver
- · Enable the USB comparators

The USB module and internal registers are reset when USBPWR is cleared. Consequently, the appropriate initialization process must be performed whenever the USB module is enabled, as described in the following subsections. Otherwise, any configuration packet sent to the USB module will be stalled, by hardware, until the reset is complete.

11.27.2 INITIALIZING THE BDT

All descriptors for a given endpoint and direction must be initialized prior to enabling the endpoint (for that direction). After a Reset, all endpoints are disabled and start with the EVEN buffer for transmit and receive directions.

Transmit descriptors must be written with the UOWN bit cleared to '0' (owned by software). All other transmit descriptor setup may be performed anytime prior to setting the UOWN bit to '1'.

Receive descriptors must be fully initialized to receive data. This means that memory must be reserved for received packet data. The pointer to that memory (physical address), and the size reserved in bytes, must be written to the descriptor. The receive descriptor UOWN bit should be initialized to '1' (owned by hardware). The DTS and STALL bits should also be configured appropriately.

If a transaction is received and the descriptor's UOWN bit is '0' (owned by software), the USB module returns a NAK handshake to the host. Usually, this causes the host to retry the transaction.

11.27.3 USB ENABLE/MODE BITS

USB mode of operation is controlled by the following enable bits: OTGEN (U1OTGCON<2>), HOSTEN (U1CON<3>), and USBEN/SOFEN (U1CON<0>).

• OTGEN:

OTGEN selects whether the PIC32MX is to act as an OTG part (OTGEN = 1) or not. OTG devices support SRP and HNP in hardware with Firmware management and have direct control over the data-line pull-up and pull-down resistors.

• HOSTEN:

HOSTEN controls whether the part is acting in the role of USB Host (HOSTEN = 1) or USB Device (HOSTEN = 0). Note that this role may change dynamically in an OTG application.

• USBEN/SOFEN:

USBEN controls the connection to USB when the USB module is not configured as a host.

If the USB module is configured as a host, SOFEN controls whether the host is active on the USB link and sends SOF tokens every 1 ms.

Note: The other USB module control registers should be properly initialized before enabling USB via these bits.

11.28 Device Operation

All communication on the USB is initiated by the host. Therefore, in Device mode, when USB is enabled USBEN = 1 (U1CON<0>), Endpoint 0 must be ready to receive control transfers. Initialization of the remaining endpoints, descriptors, and buffers can be delayed until the host selects a configuration for the device. Refer to Chapter 9 of the *"Universal Serial Bus Specification, Revision 2.0"* for more information on this subject.

The following steps are performed to respond to a USB transaction:

- 1. Software pre-initializes the appropriate BDs, and sets the UOWN bits to '1' to be ready for a transaction.
- Hardware receives a TOKEN PID (IN, OUT, SETUP) from the USB host, and checks the appropriate BD.
- 3. If the transaction will be transmitted (IN), the module reads packet data from data memory.
- 4. Hardware receives a DATA PID (DATA0/1), and sends or receives the packet data.
- 5. If a transaction is received (SETUP, OUT), the module writes packet data to data memory.

- The module issues, or waits for, a handshake PID (ACK, NAK, STALL), unless the endpoint is setup as an isochronous endpoint (EPHSHK bit UEPMx<0> is cleared).
- 7. The module updates the BD, and writes the UOWN bit to '0' (SW owned).
- 8. The module updates the U1STAT register, and sets the TRNIF interrupt.
- 9. Software reads the U1STAT register, and determines the endpoint and direction for the transaction.
- 10. Software reads the appropriate BD, completes all necessary processing, and clears the TRNIF interrupt.
- Note: For transmitted (IN) transactions (host reading data from the device), the read data must be ready when the Host begins USB signaling. Otherwise, the USB module will send a NAK handshake if UOWN is '0'.

11.28.1 RECEIVING AN IN TOKEN IN DEVICE MODE

Perform the following steps to receive an IN token in Device mode:

- 1. Attach to a USB host and enumerate as described in Chapter 9 of the USB 2.0 specification.
- 2. Populate the data buffer with the data to send to the host.
- 3. In the appropriate (EVEN or ODD) transmit buffer descriptor for the desired endpoint:
 - a) Set up the control bit field (BDnSTAT) with the correct data toggle (DATA0/1) value and the byte count of the data buffer.
 - b) Set up the address bit field (BDnADR) with the starting address of the data buffer.
 - c) Set the UOWN bit field to '1'.
- 4. When the USB module receives an IN token, it automatically transmits the data in the buffer. Upon completion, the module updates the Status bit field (BDnSTAT), clears the UOWN bit and sets the transfer complete interrupt (U1IR<TRNIF>).

11.28.2 RECEIVING AN OUT TOKEN IN DEVICE MODE

Perform the following steps to receive an OUT token in Device mode:

- 1. Attach to a USB host and enumerate as described in Chapter 9 of the USB 2.0 specification.
- 2. Create a data buffer with the amount of data you are expecting from the host.
- 3. In the appropriate (EVEN or ODD) transmit buffer descriptor for the desired endpoint:
 - a) Set up the Status bit field (BDnSTAT) with the correct data toggle (DATA0/1) value and the byte count of the data buffer.
 - b) Set up the address bit field (BDnADR) with the starting address of the data buffer.
 - c) Set the UOWN bit of the Status bit field to '1'.
- 4. When the USB module receives an OUT token, it will automatically receive the data the host sent into the buffer. Upon completion, the module updates the Status bit field (BDnSTAT), clears the UOWN bit and sets the transfer complete interrupt (U1IR<TRNIF>).

11.29 Host Mode Operation

In Host mode, only Endpoint 0 is used (all other endpoints should be disabled). Since the host initiates all transfers, the BD does not require immediate initialization. However, the BDs must be configured before a transfer is initiated – which is done by writing to the U1TOK register.

The following sections describe how to perform common Host mode tasks. In Host mode, USB transfers are invoked explicitly by the host software. The host software is responsible for initiating the setup, data, and status stages of all control transfers. The acknowledge (ACK or NAK) is generated automatically by the hardware, based on the CRC. Host software is also responsible for scheduling packets so that they do not violate USB protocol. All transfers are performed using the Endpoint 0 Control register (U1EP0) and BDs.

11.30 Configuring the SOF Threshold

The module counts down the number of bits that could be transmitted within the current USB full-speed frame. Since 12,000 bits can be transmitted during the 1 ms frame time, a counter, not visible to software, is loaded with the value '12,000' at the start of each frame. The counter decrements once for each bit time in the frame. When the counter reaches zero the next frame's SOF packet is transmitted, see Figure 11-9.

The SOF threshold register (U1SOF) is used to ensure that no new tokens are started too close to the end of a frame. This prevents a conflict with the next frame's SOF packet. When the counter reaches the threshold value of the U1SOF register (the value in the U1SOF register is in terms of bytes), no new tokens are started until after the SOF has been transmitted. Thus, the USB module attempts to ensure that the USB link is idle when the SOF token needs to be transmitted.

This implies that the value programmed into the U1SOF register must reserve enough time to insure the completion of the worst-case transaction. Typically, the worst-case transaction is an IN token followed by a maximum-sized data packet from the target, followed by the response from the host. If the host is targeting a low-speed device that is bridging through a full-speed hub, the transaction will also include the special PRE token packets.

FIGURE 11-9: ALLOCATION OF BITS FOR A FULL-SPEED FRAME

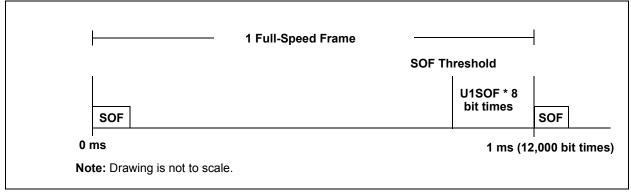

Table 11-4 and Table 11-5 show examples of calculating worst-case bit times.

- **Note 1:** While the U1SOF register value is described in terms of bytes, these examples show the result in terms of bits.
 - 2: In the second table, the IN, DATA, and HANDSHAKE packets are transmitted at low speed (8 times slower than full speed).
 - 3: These calculations do not take the possibility that the packet data needs to be bit-stuffed for NRZI encoding into account.

TABLE 11-4: EXAMPLE OF SOF THRESHOLD CALCULATION: FULL SPEE

Packet	Fields	Bits
IN	SYNC, PID, ADDR, ENDP, CRC5, EOP	35
Turnaround ⁽¹⁾		8
DATA	SYNC, PID, DATA ⁽²⁾ , CRC16, EOP	547
Turnaround		2
HANDSHAKE	SYNC, PID, EOP	19
Inter-packet		2
Total	· · · ·	613

Note 1: Inter-packet delay of 2. An additional 5.5 bit times of latency is added to represent a worst-case propagation delay through 5 hubs.

2: Using 64-bytes maximum packet size for this example calculation.

Packet	Fields	Bits	FS Bits				
PRE	SYNC, PID	16	16				
Hub setup		4	4				
IN	SYNC, PID, ADDR, ENDP, CRC5, EOP	SYNC, PID, ADDR, ENDP, CRC5, EOP 35					
Turnaround ⁽¹⁾		8	8				
DATA	SYNC, PID, DATA ⁽²⁾ , CRC16, EOP	99	792				
Turnaround		2	2				
PRE	SYNC, PID	16	16				
HANDSHAKE	SYNC, PID, EOP	19	152				
Inter-packet		2	2				
Total	·	·	1272				

TABLE 11-5: EXAMPLE OF SOF THRESHOLD CALCULATION: LOW SPEED VIA HUB

Note 1: Inter-packet delay of 2. An additional 5.5 bit times of latency is added to represent a worst-case propagation delay through 5 hubs.

2: Packets limited to 8-bytes maximum in Low-Speed mode.

Note:	Refer to Section 5.11.3 "Calculating Bus										
	Transaction Times" in the USB 2.0 spec-										
	ification for details on calculating bus										
	transaction time.										

11.31 Enabling Host Mode and Discovering a Connected Device

To enable Host mode, perform the following steps:

- Enable Host mode (U1CON<HOSTEN> = 1). This enables the D+ and D- pull-down resistors, and disables the D+ and D- pull-up resistors. To reduce noise on the bus, disable the SOF packet generation by writing the SOF Enable bit to '0' (U1CON<SOFEN> = 0).
- 2. Enable the device attach interrupt (U1IE<ATTACHIE> = 1).
- Wait for the device attach interrupt (U1IR<ATTACHIF>). This is signaled by the USB device changing the state of D+ or D- from '0' to '1' (SE0 to JSTATE). After it occurs, wait for the device power to stabilize (10 ms is minimum, 100 ms is recommended).
- Check the state of the JSTATE and SE0 bits in the control register U1CON.
 If U1CON<JSTATE> is '0', the connecting device is low speed; otherwise, the device is full speed.
- If the connecting device is low speed, set the low-speed enable bit in the address register (U1ADDR<LSPDEN>= 1), and the low-speed bit in the Endpoint 0 Control register (U1EP0<LSPD> = 1). But, if the device is full speed, clear these bits.
- Reset the USB device by sending the Reset signaling for at least 50 ms (U1CON<USBRST> = 1). After 50 ms, terminate the Reset (U1CON<USBRST> = 0).
- Enable SOF packet generation to keep the connected device from going into suspend (U1CON<SOFEN> = 1).
- 8. Wait 10 ms for the device to recover from Reset.
- 9. Perform enumeration as described in Chapter 9 of the USB 2.0 specification.

11.31.1 HOST TRANSACTIONS

When acting as a host, a transaction consists of the following:

- Software configures the appropriate BD (Endpoint n, DIR, PPBI), and sets the UOWN bit to '1' (HW owned).
- Software checks the state of TOKBUSY (U1CON<5>) to verify that any previous transaction has completed.
- 3. Software writes the address of the target device in the U1ADDR register.
- Software writes the endpoint number and the desired TOKEN PID (IN, OUT, or SETUP) to the U1TOK register.

- 5. Hardware reads the BD to determine the appropriate action, and to obtain the pointer to data memory.
- 6. Hardware issues the correct TOKEN PID (IN, OUT, SETUP) on the USB link.
- If the transaction is a transmit transaction (OUT, SETUP), the USB module reads the packet data out of data memory. Then the module follows with the desired DATA PID (DATA0/DATA1) and packet data.
- 8. If the transaction is a receive transaction (IN), the USB module waits to receive the DATA PID and packet data. Hardware writes the packet data to memory.
- Hardware issues or waits for a Handshake PID (ACK, NAK, or STALL), unless the endpoint is set up as an isochronous endpoint (EPHSHK bit U1EPx<0> is cleared).
- 10. Hardware updates the BD, and writes the UOWN bit to '0' (SW owned).
- 11. Hardware updates the U1STAT register, and sets the TRNIF (U1IR<3>) interrupt.
- 12. Hardware reads the next BD (EVEN or ODD) to see whether it is owned by the USB module. If it is, hardware begins the next transaction.
- 13. Software should read the U1STAT register, and then clear the TRNIF interrupt.

If Software does not set the UOWN bit to '1' in the appropriate BD prior to writing the U1TOK register, the module will read the descriptor and do nothing.

11.32 Completing a Control Transaction to a Connected Device

Complete all of the following steps to discover a connected device:

- 1. Set up the Endpoint Control register for bidirectional control transfers, U1EP0<4:0> = 0x0D.
- 2. Place an 8-byte of the device setup packet in the appropriate memory buffer. See Chapter 9 of the USB 2.0 specification for information on the device framework command set.
- 3. Initialize the current (EVEN or ODD) TX EP0 BD to transfer the 8 byte device framework command (for example, a GET DEVICE DESCRIPTOR command).
 - a) Set the BD status (BD0STAT) to 0x8008 UOWN bit set, byte count of 8.
 - b) Set the BD data buffer address (BD0ADR) to the starting address of the 8-byte memory buffer containing the command, if it is not already initialized.
- Set the USB address of the target device in the address register U1ADDR<6:0>. After a USB bus Reset, the device USB address will be zero. After enumeration, it must be set to another value, between 1 and 127, by the host software.
- 5. Write the token register with a SETUP command to Endpoint 0, the target device's default control pipe (U1TOK = 0xD0). This will initiate a SETUP token on the bus followed by a data packet. The device handshake will be returned in the PID field of BD0STAT after the packets complete. When the module updates BD0STAT, a transfer done interrupt will be asserted (U1IR<TRNIF>). This completes the setup stage of the setup transfer as described in Chapter 9 of the USB specification.
- 6. To initiate the data stage of the setup transaction (for example, get the data for the GET DEVICE DESCRIPTOR command), set up a buffer in memory to store the received data.
- Initialize the current (EVEN or ODD) RX or TX (RX for IN, TX for OUT) EP0 BD to transfer the data.
 - a) Set the BD status (BD0STAT) UOWN bit to '1', data toggle (DTS) to DATA1 and byte count to the length of the data buffer.
 - b) Set the BD data buffer address (BD0ADR) to the starting address of the data buffer if it is not already initialized.
- 8. Write the Token register with the appropriate IN or OUT token to Endpoint 0, the target device's default control pipe) for example, an IN token for a GET DEVICE DESCRIPTOR command (U1TOK = 0x90). This will initiate an IN token on the bus followed by a data packet from the device to the host. When the data packet com-

pletes, the BD0STAT is written and a transfer done interrupt will be asserted (U1IR<TRNIF>). For control transfers with a single packet data phase, this completes the data phase of the setup transaction. If more data needs to be transferred, return to step 8.

- 9. To initiate the status stage of the setup transaction, set up a buffer in memory to receive or send the zero length status phase data packet.
- 10. Initialize the current (EVEN or ODD) TX EP0 BD to transfer the status data.
 - a) Set the BD status (BD0STAT) to 0x8000 UOWN bit to '1', data toggle (DTS) to DATA0 and byte count to '0'.
 - b) Set the BDT buffer address field to the start address of the data buffer.
- 11. Write the Token register with the appropriate IN or OUT token to Endpoint 0, the target device's default control pipe) for example, an OUT token for a GET DEVICE DESCRIPTOR command (U1TOK = 0x10). This will initiate a token on the bus, followed by a zero length data packet from the host to the device. When the data packet completes, the BD is updated with the hand-shake from the device, and a transfer done interrupt will be asserted (U1IR<TRNIF>). This completes the status phase of the setup transaction.

Note: Some devices can only effectively respond to one transaction per frame.

11.33 Data Transfer with a Target Device

Complete all of the following steps to discover and configure a connected device.

 Write the EP0 Control register (U1EP0) to enable transmit and receive transfers as appropriate with handshaking enabled (unless isochronous transfers are to be used). If the target device is a low-speed device, also set the Low-Speed Enable bit (U1EP0<LSPD>). If you want the hardware to automatically retry indefinitely if the target device asserts a NAK on the transfer, clear the Retry Disable bit (U1EP0<RETRY-DIS>).

Note: Use of automatic indefinite retries can lead to a deadlock condition if the device never responds.

- Set up the current buffer descriptor (EVEN or ODD) in the appropriate direction to transfer the desired number of bytes.
- 3. Set the address of the target device in the address register (U1ADDR<6:0>).
- Write the Token register (U1TOK) with an IN or OUT token as appropriate for the desired endpoint. This triggers the module's transmit state machines to begin transmitting the token and the data.
- 5. Wait for the transfer done interrupt (U1IR<TRNIF>). This will indicate that the BD has been released back to the microprocessor and the transfer has completed. If the retry disable bit is set, the handshake (ACK, NAK, STALL or ERROR (0xf)) will be returned in the BD PID field. If a stall interrupt occurs, then the pending packet must be dequeued and the error condition in the target device cleared. If a detach interrupt occurs (SE0 for more than 2.5 μs), then the target has detached (U1IR<DETACHIF>).
- Once the transfer done interrupt (U1IR<TRNIF>) occurs, the BD can be examined and the next data packet queued by returning to step 2.

Note: USB speed, transceiver and pull-ups should only be configured during the module set-up phase. It is not recommended to change these settings while the module is enabled.

11.33.1 USB LINK STATES

Three possible link states are described in the following subsections:

- Reset
- · Idle and Suspend
- Resume Signalling

11.33.1.1 Reset

As a host, software is required to drive Reset signaling. It may do this by setting USBRST (U1CON<4>). As per the USB specification, the host must drive the Reset for at least 50 ms. (This does not have to be continuous Reset signaling. Refer to the USB 2.0 specification for more information.) Following Reset, the host must not initiate any downstream traffic for another 10 ms.

As a device, the USB module will assert the URSTIF (U1IR<0>) interrupt when it has detected Reset signaling for 2.5 μ s. Software must perform any Reset initialization processing at this time. This includes setting the address register to 0x00 and enabling Endpoint 0. The URSTIF interrupt will not be set again until the Reset signaling has gone away and then has been detected again for 2.5 μ s.

11.33.1.2 Idle and Suspend

The Idle state of the USB is a constant J state. When the USB has been Idle for 3 ms, a device should go into suspend state. During active operation, the USB host will send a SOF token every 1 ms, preventing a device from going into suspend state.

Once the USB link is in the suspend state, a USB host or device must drive resume signaling prior to initiating any bus activity. (The USB link may also be disconnected.)

As a USB host, software should consider the link in suspend state as soon as software clears the SOFEN (U1CON<0>).

As a USB device, hardware will set the IDLEIF (U1IR<4>) interrupt when it detects a constant Idle on the bus for 3 ms. Software should consider the link in suspend state when the IDLEIF interrupt is set.

Once a suspend condition has been detected, the software may wish to place the USB hardware in a Suspend mode by setting USUSPEND (U1PWRC<1>). The hardware Suspend mode gates the USB module's 48 MHz clock and places the USB transceiver in a Low-Power mode.

Additionally, the user may put the PIC32MX into Sleep mode while the link is suspended.

11.33.1.3 Driving Resume Signaling

If software wants to wake the USB from suspend state, it may do so by setting RESUME (U1CON<2>). This will cause the hardware to generate the proper resume signaling (including finishing with a low-speed EOP if a host).

A USB device should not drive resume signaling unless the Idle state has persisted for at least 5 ms. The USB host also must have enabled the function for remote wake-up. Software must set RESUME for 1-15 ms if a USB device, or >20 ms if a USB host, then clear it to enable remote wake-up. For more information on RESUME signaling, see Section 7.1.7.7, 11.9 and 11.4.4 in the USB 2.0 specification.

Writing RESUME will automatically clear the special hardware suspend (low-power) state.

If the part is acting as a USB host, software should, at minimum, set the SOFEN (U1CON<0>) after driving its resume signaling. Otherwise, the USB link would return right back to the suspend state. Also, software must not initiate any downstream traffic for 10 ms following the end of resume signaling.

11.33.1.4 Receiving Resume Signaling

When the USB logic detects resume signaling on the USB bus for 2.5 μ s, hardware will set the RESUMEIF (U1IR<5>) interrupt.

A device receiving resume signaling must prepare itself to receive normal USB activity. A host receiving resume signaling must immediately start driving resume signaling of its own. The special hardware suspend (lowpower) state is automatically cleared upon receiving any activity on the USB link.

Reception of any activity on the USB link (this may be due to resume signaling or a link disconnect) while the PIC32MX is in Sleep mode will cause the ACTVIF (U10TGIR<4>) interrupt to be set. This will cause wake-up from Sleep.

11.33.1.5 SRP Support

SRP support is not required by non-OTG applications. SRP may only be initiated at full speed. Refer to the On-The-Go Supplement specification for more information regarding SRP.

An OTG A-device or embedded host may decide to power-down the VBUS supply when it is not using the USB link. Software may do this by clearing VBUSON (U10TGCON<3>). When the VBUS supply is powered down, the A-device is said to have ended a USB session.

Note:	When the A-device powers down the VBUS supply, the B-device must disconnect its pull-up resistor unless signalling a desire
	to become host during HNP negotiation.
	Refer to Section 11.33.1.6 "HNP".

An OTG A-device or embedded host may repower the VBUS supply at any time to initiate a new session. An OTG B-device may also request that the OTG A-device repower the VBUS supply to initiate a new session. This is the purpose of the SRP.

Prior to requesting a new session, the B-device must first check that the previous session has definitely ended. To do this, the B-device must check that:

- 1. VBUS supply is below the session end voltage.
- 2. Both D+ and D- have been low for at least 2 ms.

The B-device will be notified of condition 1 by the SES-ENDIF (U10TGIR<2>) interrupt.

Software can use the LSTATEIF (U1OTGIR<5>) bit and the 1 ms timer to identify condition 2.

The B-device may aid in achieving condition 1 by discharging the VBUS supply through a resistor. Software may do this by setting VBUSDIS (U10TGCON<0>).

The B-device then proceeds by pulsing the D+ data line. Software should do this by setting DPPULUP (U10TGCON<7>). The data line should be held high for 5-10 ms.

After these initial conditions are met, the B-device may begin requesting the new session. It begins by pulsing the VBUS supply. Software should do this by setting VBUSCHG (U10TGCON<1>).

When an A-device detects SRP signaling (either via the ATTACHIF (U1IR<6>) interrupt or via the SESVDIF (U1OTGIR<3>) interrupt), the A-device must restore the VBUS supply by setting VBUSON (U1OTGCON<3>).

The B-device should not monitor the state of the VBUS supply while performing VBUS supply pulsing. Afterwards, if the B-device does detect that the VBUS supply has been restored (via the SESVDIF (U10TGIR<3>) interrupt), it must reconnect to the USB link by pulling up D+. The A-device must complete the SRP by enabling VBUS and driving reset signalling.

11.33.1.6 HNP

An OTG application with a micro-AB receptacle must support HNP. HNP allows an OTG B-device to temporarily become the USB host. The A-device must first enable HNP in the B-device. HNP may only be initiated at full-speed. Refer to the On-The-Go supplement for more information regarding HNP.

After being enabled for HNP by the A-device, the B-device can request to become the host any time that the USB link is in suspend state by simply indicating a disconnect. Software may accomplish this by clearing the DPPULUP bit (U10TGCON<7>).

When the A-device detects the disconnect condition (via the URSTIF (U1IR<0>) interrupt), the A-device may allow the B-device to take over as host. The A-device does this by signaling connect as a full-speed device. Software may accomplish this by disabling host operation, HOSTEN = 0 (U1CON<3>), and connecting as a device (DPPULUP = 1). If the A-device instead responds with resume signaling, the A-device will remain as host.

When the B-device detects the connect condition (via ATTACHIF (U1IR<6>), the B-device becomes host. The B-device drives Reset signaling prior to using the bus.

When the B-device has finished in its role as host, it stops all bus activity and turns on its D+ pull-up resistor by disabling host operations (HOSTEN = 0) and reconnecting as a device (DPPULUP = 1).

Then the A-device detects a suspend condition (Idle for 3 ms), the A-device turns off its D+ pull-up. Alternatively the A-device may also power-down the VBUS supply to end the session.

When the A-device detects the connect condition (via ATTACHIF), the A-device resumes host operation, and drives Reset signaling.

11.33.2 CLOCK REQUIREMENTS

For proper USB operation, the USB module must be clocked with a 48 MHz clock. This clock source is used to generate the timing for USB transfers; it is the clock source for the SIE. The control registers are clocked at the same speed as the CPU (refer to Figure 11-1).

The USB module clock is derived from the Primary Oscillator (POSC) for USB operation. A USB PLL and input prescalers are provided to allow 48 MHz clock generation from a wide variety of input frequencies. The USB PLL allows the CPU and the USB module to operate at different frequencies while both use the POSC as a clock source. To prevent buffer overruns and timing issues, the CPU core must be clocked at a minimum of 16 MHz.

The USB module can also use the on-board Fast RC oscillator (FRC) as a clock source. When using this clock source, the USB module will not meet the USB timing requirements. The FRC clock source is intended to allow the USB module to detect a USB wake-up and report it to the interrupt controller when operating in low-power modes. The USB module must be running from the Primary oscillator before beginning USB transmissions.

11.34 Interrupts

The USB module uses interrupts to signal USB events such as a change in status, data received and buffer empty events, to the CPU. Software must be able to respond to these interrupts in a timely manner.

11.35 Interrupt Control

Each interrupt source in the USB module has an interrupt flag bit and a corresponding enable bit. In addition, the UERRIF bit (U1IR<1>) is a logical OR of all the enabled error flags and is read-only. The UERRIF bit can be used to poll the USB module for events while in an Interrupt Service Routine (ISR).

11.36 USB Module Interrupt Request Generation

The USB module can generate interrupt requests from a variety of events. To interface these interrupts to the CPU, the USB interrupts are combined such that any enabled USB interrupt will cause a generic USB interrupt (if the USB interrupt is enabled) to the interrupt controller, see Figure 11-11. The USB ISR must then determine which USB event(s) caused the CPU interrupt and service them appropriately. There are two layers of interrupt registers in the USB module. The top level of bits consists of overall USB status interrupts in the U10TGIR and U1IR registers. The U10TGIR and U1IR bits are individually enabled through the corresponding bits in the U1OTGIE and U1IE registers. In addition, the USB Error Condition bit (UERRIF) passes through any interrupt conditions in the U1EIR register enabled via the U1EIE register bits.

11.37 Interrupt Timing

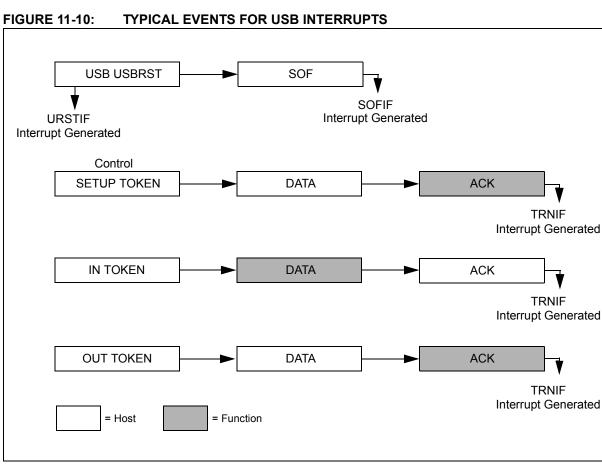

Interrupts for transfers are generated at the end of the transfer. Figure 11-10 shows some typical event sequences that can generate a USB interrupt and when that interrupt is generated. There is no mechanism by which software can manually set an interrupt bit.

The values in the Interrupt Enable registers (U1IE, U1EIE, U1OTGIE) only affect the propagation of an interrupt condition to the CPU's interrupt controller. Even though an interrupt is not enabled, interrupt flag bits can still be polled and serviced.

11.38 Interrupt Servicing

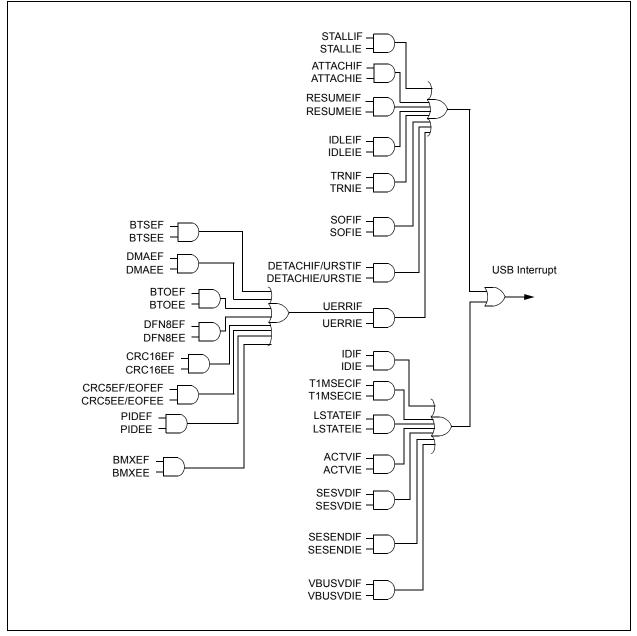

Once an interrupt bit has been set by the USB module (in U1IR, U1EIR or U1OTGIR), it must be cleared by software by writing a '1' to the appropriate bit position to clear the interrupt. The USB Interrupt, USBIF (IFS1<25>), must be cleared before the end of the ISR.

12.0 I/O PORTS

Note:	This data sheet summarizes the features of									
	the PIC32MX3XX/4XX family of devices. It									
	is not intended to be a comprehensive refer-									
	ence source. Refer to the "PIC32MX Family									
	Reference Manual" (DS61132) for a									
	detailed description of this peripheral.									

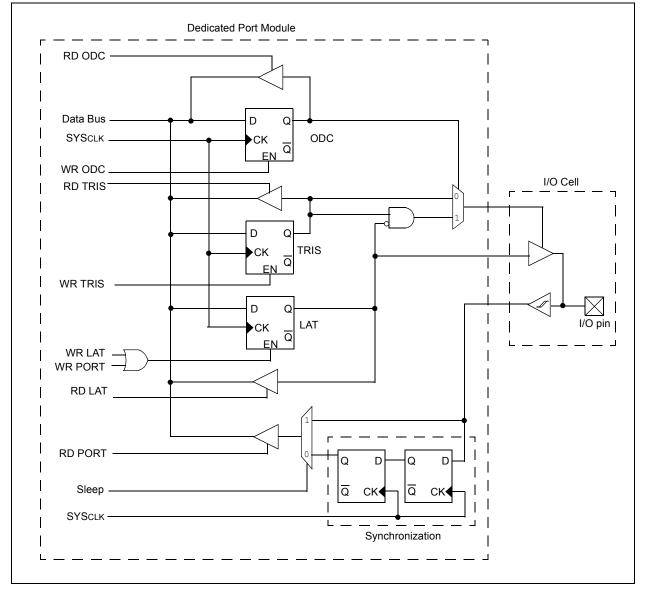

The general purpose I/O pins can be considered the simplest of peripherals. They allow the PIC[®] MCU to monitor and control other devices. To add flexibility and functionality, some pins are multiplexed with alternate function(s). These functions depend on which peripheral features are on the device. In general, when a peripheral is functioning, that pin may not be used as a general purpose I/O pin.

Following are some of the key features of this module:

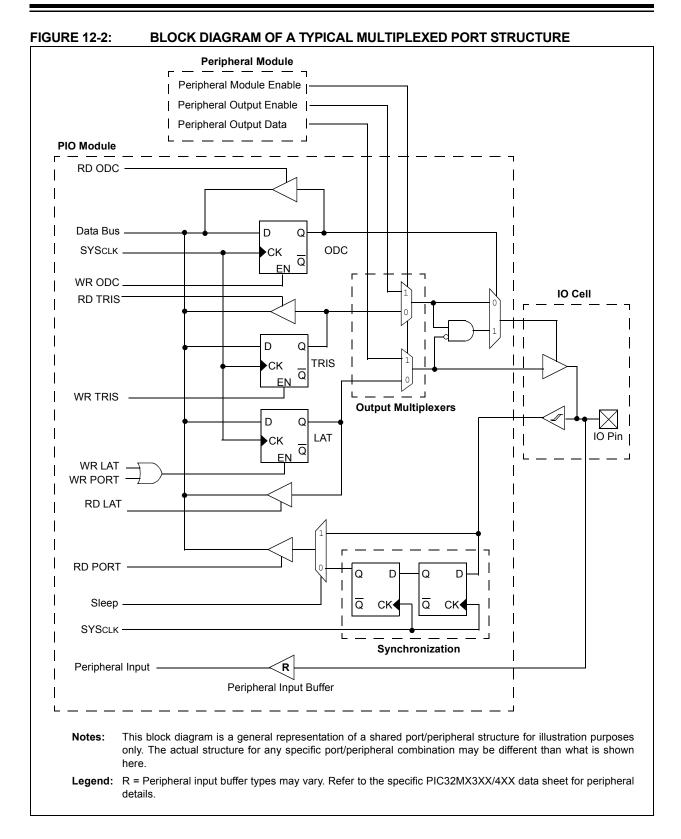

- Individual output pin open-drain enable/disable
- · Individual input pin weak pull-up enable/disable
- Monitor selective inputs and generate interrupt when change in pin state is detected
- Operation during CPU Sleep and Idle modes
- Fast bit manipulation using CLR, SET and INV registers

Figure 12-1 shows a block diagram of a typical I/O port, whereas Figure 12-2 shows a block diagram of a typical multiplexed I/O port.

TABLE 12-1: PORTA SFR SUMMARY

Note: TRISA, PORTA, LATA and ODCA registers are not implemented on 64-pin devices, and read as '0'.

Note: JTAG program/debug port is multiplexed with port pins RA0, RA1, RA4 and RA5 on 100-pin devices. At power-on-reset, these pins are controlled by the JTAG port. To use these pins for general purpose I/O, the user's application code must clear JTAGEN (DDPCON<3>) bit = 0. To use these pins for JTAG program/debug, the user's application code must maintain JTA-GEN bit = 1.

REGISTER 12-7: CNPUE: INPUT CHANGE NOTIFICATION PULL-UP ENABLE⁽¹⁾

bit 31-22 **Reserved:** Maintain as '0'; ignore read

- bit 21-0 CNPUE<21:0>: CNPUE Register bits
 - If a port pin is configured as an input (corresponding TRISx bit = 1).
 - 1 = Port pin pull-up enabled
 - 0 = Port pin pull-up disabled

If a port pin is configured as an output, it is recommended to disable the corresponding CNPUEx bit.

Note 1: Depending on the device, certain register bits or the entire register may not be implemented. Refer to Table 12.1 for specific register and bit assignments.

12.2 Parallel I/O (PIO) Ports

All port pins have three registers (TRIS, LAT, and PORT) that are directly associated with their operation.

TRIS is a data direction or tri-state control register that determines whether a digital pin is an input or an output. Setting a TRISx register bit = 1 configures the corresponding I/O pin as an input; setting a TRISx register bit = 0 configures the corresponding I/O pin as an output. All port I/O pins are defined as inputs after a device Reset. Certain I/O pins are shared with analog peripherals and default to analog inputs after a device Reset.

PORT is a register used to read the current state of the signal applied to the port I/O pins. Writing to a PORTx register performs a write to the port's latch, LATx register, latching the data to the port's I/O pins.

LAT is a register used to write data to the port I/O pins. The LATx latch register holds the data written to either the LATx or PORTx registers. Reading the LATx latch register reads the last value written to the corresponding port or latch register.

Not all port I/O pins are implemented on some devices, therefore, the corresponding PORTx, LATx and TRISx register bits will read as zeros. See **Section 12.1 "Port Registers"**.

12.2.1 CLR, SET AND INV REGISTERS

Every I/O module register has a corresponding CLR (clear), SET (set) and INV (invert) register designed to provide fast atomic bit manipulations. As the name of the register implies, a value written to a SET, CLR or INV register effectively performs the implied operation, but only on the corresponding base register and only bits specified as '1' are modified. Bits specified as '0' are not modified.

Reading SET, CLR and INV registers returns undefined values. To see the affects of a write operation to a SET, CLR or INV register, the base register must be read.

To set PORTC bit 0, write to the LATSET register:

LATCSET = 0x0001;

To clear PORTC bit 0, write to the LATCLR register:

LATCCLR = 0x0001;

To toggle PORTC bit 0, write to the LATINV register:

LATCINV = 0x0001;

Note: Using a PORTxINV register to toggle a bit is recommended because the operation is performed in hardware atomically, using fewer instructions as compared to the traditional read-modify-write method shown below:

PORTC ^= 0x0001;

12.2.2 DIGITAL INPUTS

Pins are configured as digital inputs by setting the corresponding TRIS register bits = 1. When configured as inputs, they are either TTL buffers or Schmitt Triggers. Several digital pins share functionality with analog inputs and default to the analog inputs at POR. Setting the corresponding bit in the ADP1CFG register = 1 enables the pin as a digital pin.

Digital only pins are capable of input voltages up to 5.5V. Any pin that shares digital and analog functionality is limited to voltages up to VDD + 0.3V.

TABLE 12-10:	MAXIMUM INPUT PIN
	VOLTAGES

Input Pin Mode(s)	Vıн (max)	
Digital Only	VIH = 5.5v	
Digital + Analog	VIH = VDD + 0.03v	
Analog	VIH = VDD + 0.03v	

Note: Refer to Section 30.0 "Electrical Characteristics" regarding the VIH specification.

Note:	Analog levels on any pin that is defined as a digital input (including the ANx pins) may
	cause the input buffer to consume current that exceeds the device specifications.

12.2.3 ANALOG INPUTS

Certain pins can be configured as analog inputs used by the ADC and Comparator modules. Setting the corresponding bits in the ADP1CFG register = 0 enables the pin as an analog input pin and must have the corresponding TRIS bit set = 1 (input). If the TRIS bit is cleared = 0 (output), the digital output level (VOH or VOL) will be converted. Any time a port I/O pin is configured as analog, its digital input is disabled and the corresponding PORTx register bit will read '0'.

12.2.4 DIGITAL OUTPUTS

Pins are configured as digital outputs by setting the corresponding TRIS register bits = 0. When configured as digital outputs, these pins are CMOS drivers or can be configured as open drain outputs by setting the corresponding bits in the ODCx Open-Drain Configuration register.

Digital output pin voltage is limited to VDD.

12.2.5 ANALOG OUTPUTS

Certain pins can be configured as analog outputs, such as the CVREF output voltage used by the comparator module. Configuring the Comparator Reference module to provide this output will present the analog output voltage on the pin, independent of the TRIS register setting for the corresponding pin.

12.2.6 OPEN-DRAIN CONFIGURATION

In addition to the PORT, LAT and TRIS registers for data control, each port pin configured as a digital output can also select between an active drive output and open-drain output. This is controlled by the Open-Drain Control register, ODCx, associated with each port. From POR, when an IO pin is configured as a digital output, its output is active drive by default. Setting a bit in the ODCx register = 1 configures the corresponding pin as an open-drain output.

The open-drain feature allows the generation of outputs higher than VDD, e.g., 5V, on any desired digital-only pins by using external pull-up resistors. The maximum open-drain voltage allowed is the same as the maximum VIH specification, typically 5.5v.

12.2.7 PERIPHERAL MULTIPLEXING

In many cases, I/O pins are multiplexed with more than one peripheral. A parallel I/O port pin that is multiplexed with a peripheral is, in general, subordinate to the peripheral.

When a peripheral is enabled and actively driving the multiplexed pin, the use of the pin as a general purpose output pin is disabled. The I/O pin may be read, but the output driver for the parallel port bit will be disabled. If, however, a peripheral is enabled, but the peripheral is not actively driving a pin, that pin may be driven by a port.

The peripheral's output buffer data and control signals are provided to a pair of multiplexers. The multiplexers select whether the peripheral or the associated port has ownership of the output data and control signals of the I/O pin. The logic also prevents "loop through", in which a port's digital output can drive the input of a peripheral that shares the same pin. Figure 12-2 shows how ports are shared with other peripherals and the associated I/O pin to which they are connected.

In general, the dominant output control of a multiplexed I/O pin can be determined by the order of the peripheral output names assigned to a pin (read from left to right). Multiplexed peripheral inputs have no priority.

For example, a pin labeled "U1TX/RF3", indicates the UART1 Transmit output, if enabled, has a higher precedence over PORTF and therefore overrides the output control of this pin.

Note: JTAG program/debug port is multiplexed with PORTA pins RA0, RA1, RA4 and RA5 on 100-pin devices; PORTB pins RB10, RB11, RB12 and RB13 on 64-pin devices. At power-on-reset, these pins are controlled by the JTAG port. To use these pins as general purpose I/O pins, the user's application code must clear JTAGEN (DDPCON<3>) bit = 0. To maintain these pins for JTAG program/debug, the user's application code must maintain JTAGEN bit = 1.

12.2.8 SOFTWARE INPUT PIN CONTROL

Some peripheral inputs assigned to an I/O pin may not take control of the I/O pin output driver. If the I/O pin associated with the peripheral is configured as an output, using the appropriate TRIS control bit, the user can manually affect the state of the peripheral's input pin through its corresponding LAT register. This behavior can be useful in some situations, especially for testing purposes, when no external signal is connected to the input pin.

In general, the following peripherals allow their input pins to be controlled manually through the LAT registers:

- External Interrupt pins
- · Timer Clock Input pins
- · Input Capture pins
- PWM Fault pins

Most serial communication peripherals, when enabled, take full control of the I/O pin so that the input pins associated with the peripheral cannot be affected through the corresponding PORT registers. These peripherals include the following modules:

- SPI
- I²C[™]
- UART

12.2.9 INPUT CHANGE NOTIFICATION

Certain PIC32MX3XX/4XX I/O port pins provide Input Change notification that can generate interrupt requests to the processor in response to a Change-Of-State (COS) on those selected input pins. The initial state of any enabled Change Notice (CN) pin must be established by reading the corresponding PORT register. This feature is capable of detecting input COS even in Sleep mode, when the clocks are disabled. Depending on the device pin count, there are up to 22 external signals (CN0 through CN21) that may be selected (enabled) for generating an interrupt request on a COS.

The following control registers are associated with the change notice module:

- CNCON
- CNEN
- CNPUE

The CNCON control register ON bit enables or disables the CN module and its ability to generate interrupts or respond to mismatch conditions.

The CNEN (change notice enable) register control bits enable each CN input. Setting any of these bits enables a CN for the corresponding pins.

The CNPUE (change notice pull-up enable) register control bits enable a weak pull-up to a corresponding CN input pin. The pull-ups act as a current source that is connected to the pin, and eliminate the need for external resistors when push button or keypad devices are connected.

Note:	Pull-up resistors on change notification						
	pins should always be disabled whenever						
	the port pin is configured as a digital						
	output.

12.2.10 CHANGE NOTICE INTERRUPTS

The Change Notice module is enabled as a source of interrupts via the respective CN interrupt enable bits:

- CNIE (IEC1<0>)
- CNIF (IFS1<0>)

The interrupt priority level bits and interrupt subpriority level bits must also be configured:

- CNIP<2:0> (IPC6<20:18>)
- CNIS<1:0> (IPC6<17:16>)

To enable CN interrupts, the ON bit (CNCON<15>) must = 1, one or more CN input pins must be enabled and the Change Notice Interrupt Enable bit, CNIE, must = 1.

To prevent possible spurious interrupts when configuring change notice interrupts, the following steps are recommended:

- 1. Disable CPU interrupts.
- Set desired CN I/O pin as input by setting corresponding TRISx register bits = 1.
 Note: If the I/O pin is shared with an analog peripheral, it may be necessary to set the corresponding AD1PCFG bit = 1 to ensure that the I/O pin is a digital input.
- 3. Enable change notice module ON (CNCON<15>) = 1.
- 4. Enable individual CN input pin(s); enable optional pull-up(s).
- 5. Read corresponding PORT registers to clear mismatch condition on CN input pins.
- 6. Configure the CN interrupt priority, CNIP<2:0>, and subpriority CNIS<1:0>.
- 7. Clear CN interrupt flag, CNIF = 0.
- 8. Enable CN interrupt enable, CNIE = 1.
- 9. Enable CPU interrupts.

The port must be read first to clear the mismatch condition, then the CN interrupt flag, CNIF (IFS1<0>), can be cleared in software. Failing to read the port before attempting to clear the CNIF bit may not allow the CNIF bit to be cleared.

In addition to enabling the CN interrupt, an Interrupt Service Routine (ISR), is required. Example 12-1 and Example 12-2 show a partial code example of an ISR.

Note: It is the user's responsibility to clear the corresponding interrupt flag bit before returning from an ISR.

EXAMPLE 12-1: CN CONFIGURATION AND INTERRUPT INITIALIZATION EXAMPLE CODE

```
The following code example illustrates a Change Notice
   interrupt configuration for pins CN1(PORTC), CN4(PORTB) and CN18(PORTF).
* /
   unsigned int value;
   /* NOTE: disable vector interrupts prior to configuration */
                         // Enable Change Notice module
   CNCON = 0 \times 8000;
                         // Enable CN1, CN4 and CN18 pins
   CNEN= 0x00040012;
   CNPUE= 0x00040012; // Enable weak pull ups for CN1, CN4 and CN18 pins
   /* read port(s) to clear mismatch on change notice pins */
   value = PORTB;
   value = PORTC;
   value = PORTF;
   IPS6SET = 0x00140000; // Set priority level=5
   IPS6SET = 0x00030000; // Set subpriority level=3
                          // Could have also done this in single
                          // operation by assigning IPS6SET = 0x00170000
   TFS1CLR = 0 \times 0001;
                         // Clear the interrupt flag status bit
   IEC1SET = 0 \times 0001;
                         // Enable Change Notice interrupts
   /* re-enable vector interrupts after configuration */
```

EXAMPLE 12-2: CN ISR EXAMPLE CODE

```
/*
   The following code example demonstrates a simple interrupt service
   routine for CN interrupts. The user's code at this vector should perform
   any application specific operations and must read the CN corresponding
   PORT registers to clear the mismatch conditions.
   Finally, the CN interrupt status flag must be cleared before exiting.
*/
void __ISR(_CHANGE_NOTICE_VECTOR, ipl3) CN_Interrupt_ISR(void)
{
   unsigned int value;
   value = PORTB
                          // Read PORTB to clear CN4 mismatch condition
   value = PORTC
                          // Read PORTC to clear CN1, CN0 mismatch condition
   ... perform application specific operations in response to the interrupt
   IFS1CLR = 0 \times 0001;
                          // Be sure to clear the CN interrupt status
                          // flag before exiting the service routine.
}
```

Note: The CN ISR code example shows MPLAB® C32 C compiler-specific syntax. Refer to your compiler manual regarding support for ISRs.

13.0 TIMER1

Note: This data sheet summarizes the features of the PIC32MX3XX/4XX family of devices. It is not intended to be a comprehensive reference source. Refer to the *"PIC32MX Family Reference Manual"* (DS61132) for a detailed description of this peripheral.

This family of PIC32MX3XX/4XX devices features one synchronous/asynchronous 16-bit timer that can operate as a free-running interval timer for various timing applications and counting external events. This timer can also be used with the Low-Power Secondary Oscillator, SOSC, for real-time clock applications. The following modes are supported:

- Synchronous Internal Timer
- Synchronous Internal Gated Timer
- Synchronous External Timer
- · Asynchronous External Timer

TABLE 13-1: TIMER1 FEATURES

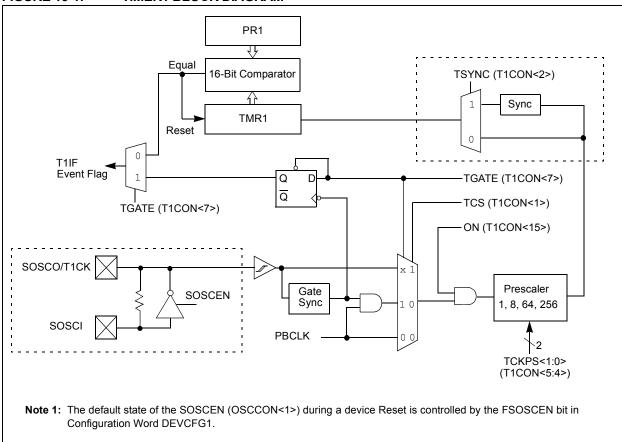

13.1 Additional Supported Features

- Selectable clock prescaler
- Timer operation during CPU Idle and Sleep mode
- Fast bit manipulation using CLR, SET and INV registers
- Asynchronous mode can be used with the Low-Power Secondary Oscillator to function as a Real-Time Clock (RTC).

Timer	Low-Power Oscillator	Asynchronous External Clock	16-Bit Synchronous Timer/Counter	32-Bit Synchronous Timer/Counter	Gated Timer	Special Event Trigger
Timer 1	Yes	Yes	Yes	No	Yes	No

bit 2	TSYNC: Timer External Clock Input Synchronization Selection bit					
	When TCS = 1:					
	1 = External clock input is synchronized					
	0 = External clock input is not synchronized					
	<u>When TCS = 0:</u>					
	This bit is ignored and read '0'.					
bit 1	TCS: Timer Clock Source Select bit					
	1 = External clock from T1CKI pin					
	0 = Internal peripheral clock					
bit 0	Reserved: Maintain as '0'; ignore read					

13.3 Modes of Operation

The 16-bit Timer1 peripheral can operate as a synchronous timer using internal or external clock sources, or as a gated timer using internal clock source and external clock pin, or as an asynchronous timer using an external asynchronous clock source, such as the low-power secondary oscillator. Each mode is easily configured and described in the following sections.

13.3.1 CONSIDERATIONS FOR ALL TIMER 1 MODES

- Timer1 module is disabled and powered off when the ON bit (T1CON<15>) = 0, thus providing maximum power savings. All other TxCON bits remain unchanged.
- Updates to the T1CON register should only be performed when the timer module is disabled, ON bit (T1CON<15>) = 0.
- Timer1 continues operating when the CPU goes into Idle mode if the "Stop In Idle mode" control bit is disabled, SIDL (TxCON<13>) bit = 0. If enabled, SIDL = 1, the timer module stops operation while the CPU is in Idle mode.
- Setting or clearing the ON bit (T1CON<15>) and any other bits in T1CON in the same instruction may cause undefined behavior. The user is advised to program the T1CON register with the desired settings with one instruction, and then set the ON bit in a subsequent instruction.

13.3.2 SYNCHRONOUS INTERNAL TIMER

In this mode, the timer clock source is the internal PBCLK (Peripheral Bus Clock), TCS (TxCON<1>) = 0. Clock synchronization is not required, therefore the Timer1 Synchronization bit, TSYNC (T1CON<2>), is ignored. The TMR1 Count register increments on every PBCLK clock cycle when the timer clock prescale <TCKPS> is 1:1.

Timer1 generates a timer match event after the TMR1 Count register matches the PR1 Period register value (mid-clock cycle on the falling edge), then resets to 0x0000 on the next PBCLK clock cycle. See **Section 13.5 "Timer Interrupts**" regarding timer events and interrupts.

For clock prescale = N (other than 1:1), the timer operates at a clock rate = PBCLK/N and the TMRx Count register increments on every Nth PBCLK clock. For further details regarding the timer prescaler, refer to **Section 13.4.2 "Timer Clock Prescaler**".

The following steps should be performed to properly configure the Timer1 peripheral for Timer mode operation.

- 1. Clear ON control bit (T1CON<15>) = 0 to disable timer.
- 2. Configure TCKPS control bits (T1CON<5:4) to select desired timer clock prescale.
- 3. Set TCS control bit (T1CON<1>) = 0 to select the internal PBCLK clock source.
- 4. Clear TMR1 register.
- 5. Load PR1 register with desired 16-bit match value.
- 6. If timer interrupts are to be used, refer to **Section 13.5 "Timer Interrupts"** for interrupt configuration steps.
- 7. Set ON control bit = 1 to enable Timer.

EXAMPLE 13-1: SYNCHRONOUS INTERNAL TIMER INITIALIZATION

T1CON = 0x0 //	Stop and Init Timer
TMR1 = 0x0; //	Clear timer register
PR1 = 0xFFFF; //	Load period register
T1CONSET = 0x8000;//	Start Timer

13.3.3 SYNCHRONOUS EXTERNAL TIMER

In this mode, the timer clock source is an external clock source or pulse applied to the T1CK pin, TCS (T1CON<1>) = 1. To provide synchronization, Timer1 synchronization bit TSYNC (T1CON<2>) must be set (= 1). The 16-bit TMR1 Count register increments on every synchronized rising edge of an external clock when the timer clock prescale <TCKPS> is 1:1.

Timer1 generates a timer match event after the TMR1 Count register matches the PR1 Period register value (mid-clock cycle on the falling edge), then resets to 0x0000 on the next synchronized external clock cycle. The timer continues to increment and repeat the period match until the timer is disabled. For further details regarding timer events and interrupts, see **Section 13.5 "Timer Interrupts"**.

For clock prescale = N (other than 1:1), the timer operates at a clock rate = (external clock/N), therefore, the TMRx Count register increments on every Nth external synchronized clock cycle. For further details regarding timer prescaler, refer to **Section 13.4.2 "Timer Clock Prescaler**".

13.3.3.1 Considerations

- When using an external clock source, regardless of the Timer1 prescale value, 2-3 external clock cycles are required, after the ON bit = 1, before the TMR1 register begins incrementing.
- Timer1 will not operate from a synchronized external clock source while the CPU is in SLEEP mode, since the synchronizing PB clock is disabled during Sleep mode.

The following steps should be performed to properly configure the Timer1 peripheral for Synchronous Counter mode operation.

- 1. Clear control bit, ON (T1CON<15>) = 0, to disable Timer1.
- 2. Select the desired timer prescaler using bits, TCKPS<1:0> (T1CON<5:4).
- 3. Set control bit, TCS (T1CON<1>) = 1, to select an external clock source.
- 4. Set control bit, TSYNC (T1CON<2>) = 1, to enable synchronization.
- 5. Clear Timer register TMR1.
- Load Period register PR1 with desired 16-bit match value.
- If timer interrupts are used, refer to Section 13.5 "Timer Interrupts" for interrupt configuration steps.
- 8. Set control bit, ON (T1CON<15>) = 1, to enable Timer1.

EXAMPLE 13-2: SYNCHRONOUS

EXTERNAL TIMER

T1CON = 0x0; T1CON = 0x0036	<pre>// Stop Timer and reset // Set prescaler=1:256, // external clock, // synchronous mode</pre>
TMR1 = 0x0; PR1 = 0x3FFF;	<pre>// Clear timer register // Load period register</pre>
T1CONSET = 0x8000;	// Start Timer

13.3.4 ASYNCHRONOUS EXTERNAL TIMER

In this mode, the timer clock source is an external clock source or pulse applied to the T1CK pin, TCS (T1CON<1>) = 1. Clock synchronization is not required, therefore, the Timer1 clock synchronization bit should be cleared, TSYNC (T1CON<2>) = 0. The 16-bit TMR1 Count register increments on every rising edge of an external clock when the timer clock prescale <TCKPS> is 1:1.

Timer1 generates a timer match event after the TMR1 Count register matches the PR1 register value (midclock cycle on the falling edge), then resets to 0x0000 on the next external clock cycle. The timer continues to increment and repeat the period match until the timer is disabled. For further details regarding timer events and interrupts, see **Section 13.5 "Timer Interrupts"**.

For clock prescale = N (other than 1:1), the timer operates at a clock rate = (external clock/N), therefore, the TMR1 Count register increments on every Nth external clock cycle. For further details regarding the timer prescaler, refer to **Section 13.4.2** "**Timer Clock Prescaler**".

13.3.4.1 Considerations

- Regardless of the Timer1 prescale setting, 2-3 external clocks are required after the ON bit = 1, before the TMR1 register begins incrementing.
- Timer1 can operate while the CPU is in Sleep mode.
- The Timer1 interrupt can be used to wake the CPU from Sleep mode.
- Typical use is with the Secondary Low-Power Oscillator, SOSC and RTCC Real-Time Clock Calendar peripheral.

Note: The SOSC oscillator may be used by the CPU as a low-power clock source. Timer 1 does not have exclusive usage to this oscillator. Refer to the "*PIC32MX Family Reference Manual*" (DS61132) regarding the operation of the Secondary Low-Power Oscillator.

13.4 Reading and Writing TMR1 Register

Due to the asynchronous nature of Timer1 operating in Asynchronous Clock mode, reading and writing to the TMR1 Count register requires synchronization between the asynchronous clock source and the internal PBCLK (Peripheral Bus Clock). Timer1 features a Timer Write Disable (TWDIS) control bit (T1CON<12>) and a TWIP (TImer Write in Progress) Status bit (T1CON<11>). These bits provide the user with 2 options for safely writing to the TMR1 Count register while Timer1 is enabled. These bits have no affect in Synchronous Clock modes.

- Option 1 Legacy Timer1 Write mode, TWDIS bit = 0. To determine when it is safe to write to the TMR1 Count register, it is recommended to poll the TWIP bit. When TWIP = 0, it is safe to perform the next write operation to the TMR1 Count register. When TWIP = 1, the previous write operation to the TMR1 Count register is still being synchronized and any additional write operations should wait until TWIP = 0.
- Option 2 New synchronized Timer1 Write mode, TWDIS bit = 1. A write to the TMR1 Count register can be performed at any time. However, if the previous write operation to the TMR1 Count register is still being synchronized, any additional write operations are ignored.

Writing to the TMR1 Count register requires 2 to 3 asynchronous external clock cycles for the value to be synchronized into the TMR1 Count register.

Reading from the TMR1 Count register requires 2 PBCLK cycle delays between the current unsynchronized value in the TMR1 Count register and the synchronized value returned by the read operation. In other words, the value read is always 2 PBCLK cycles behind the actual value in the TMR1 Count register.

The following steps should be performed to properly configure the Timer1 peripheral for Asynchronous Counter mode operation.

- 1. Clear control bit, ON (T1CON<15>) = 0, to disable Timer1.
- 2. Select the desired timer prescaler using bits, TCKPS<1:0> (T1CON<5:4).
- 3. Set control bit, TCS (T1CON<1>) = 1, to select an external clock source.
- 4. Set control bit, TSYNC (T1CON<2>) = 0, to disable synchronization.
- 5. Clear Timer Register, TMR1.
- 6. Load Period Register, PR1, with desired 16-bit match value.
- 7. If timer interrupts are used, refer to **13.5 "Timer Interrupts**" for interrupt configuration steps.
- Set control bit, ON (T1CON<15>) = 1, to enable Timer1.

EXAMPLE 13-3: ASYNCHRONOUS

EXTERNAL TIMER

T1CON = 0x0; T1CON = 0x0012;	//	Stop Time and reset Set prescaler at 1:8, external clock source,
TMR1 = 0x0; PR1 = 0x7FFF;	 	asynchronous mode Clear timer register Load period register
T1CONSET = 0x8000;		1 5

13.4.1 Synchronous Internal Gated Timer

In this mode, the timer clock source can only be the internal PBCLK (Peripheral Bus Cock), TCS (T1CON<1>) = 0. The T1CK pin provides the gating mechanism to enable and disable the timer counting, TGATE (T1CON<7>) = 1. Clock synchronization is not required, therefore Timer1 synchronization bit, TSYNC (T1CON<2>), is ignored. The 16-bit TMR1 Count register is enabled on the rising edge of the T1CK pin and increments on every internal PBCLK cycle when the timer clock prescale <TCKPS> is 1:1.

The timer increments until the TMR1 Count register matches the PR1 register value. The TMR1 Count register resets to 0x0000 on the next PBCLK clock cycle. A timer match event is not generated. The timer continues to increment and repeat the period match until the falling edge of the T1CK pin or the timer is disabled. On the falling edge of the gate signal, a timer gate event is generated and the TMR1 Count register stops counting, but is not reset to 0x0000. The TMR1 Count register must be reset in software. For further details regarding timer events and interrupts, see **Section 13.5 "Timer Interrupts"**.

For clock prescale = N (other than 1:1), the timer operates at a clock rate = (PBCLK/N); therefore, the TMR1 Count register increments on every Nth PBCLK clock cycle. For further details regarding timer prescaler, refer to **Section 13.4.2 "Timer Clock Prescaler"**.

The following steps should be performed to properly configure the Timer1 peripheral for Gated Timer mode operation:

- 1. Clear control bit, ON (T1CON<15>) = 0, to disable Timer1.
- 2. Select the desired timer prescaler using bits, TCKPS<1:0> (T1CON<5:4>).
- 3. Set control bit, TCS (T1CON<1>) = 0, to select the internal clock source.
- 4. Set control bit TGATE (T1CON<6>) = 1.
- 5. Clear Timer register, TMR1.
- 6. Load Period register, PR1, with desired 16-bit match value.
- If timer interrupts are used, refer to Section 13.5 "Timer Interrupts" for interrupt configuration steps.
- 8. Set control bit ON, (T1CON<15>) = 1, to enable Timer1.

EXAMPLE 13-4: SYNCHRONOUS INTERNAL GATED TIMER INITIALIZATION

T1CON = 0x0060;	 	Stop Timer and reset Enable gated mode, prescaler at 1:64, internal clock source
		Clear timer register Load period register
$T1CONSET = 0 \times 8000;$	//	Start Timer

13.4.2 TIMER CLOCK PRESCALER

Timer clock prescale bits, TCKPS<1:0> (T1CON<5:4>), are used to divide the timer clock source, permitting the TMR register to increment on every 1, 8, 64, or 256 (PBCLK or external) clock cycles. For example, if the clock prescale is 1:8, then the timer increments on every 8th timer clock cycle.

Associated with the clock prescale selection bits is a prescale counter. This prescale counter is cleared when any of the following conditions occur:

- · Any device Reset, except a Power-on Reset
- The timer is disabled

• A write to the TMR register

- **Note:** When the timer clock source is external and the timer clock prescale = N (other than 1:1), 2 to 3 external clock cycles are required to reset and synchronize the prescaler.
- When the timer clock source is external and the timer clock prescale = N (other than 1:1), 2 to 3 external clock cycles are required, after the timer ON bit is set = 1, before the TMR1 Count register increments.
- After a timer match event (TMR1 = PR1) and depending on the timer clock prescale setting N (other than 1:1), the timer will require N/2 additional (PBCLK or external) clock cycles before the TMR1 Counter register reset to 0x0000. Reading the TMR1 Count register just after the timer match event, but before the TMR1 Count register is rest, will return the timer match value.

13.5 Timer Interrupts

Timer1 can generate an interrupt on a period match event or a gate event, caused by the falling edge of the external gate signal.

Timer1 sets the interrupt flag bit, T1IF (IFS0<4>), whenever a Timer1 event is generated. Refer to a specific Timer mode for details regarding event conditions. When a Timer1 event is generated, the interrupt flag bit is set within 1 PBCLK + 2 SYSCLK cycles. If Timer1 Interrupt Enable bit is set, T1IE (IEC0<4>) = 1, an interrupt is generated.

The Timer1 module is enabled as a source of interrupts through its respective interrupt enable bit, T1IE (IEC0<4>). The Timer1 Interrupt Flag, T1IF (IFS0<4>), must be cleared in software.

The interrupt priority level bits and interrupt subpriority level bits must be also be configured:

- T1IP<2:0> (IPC1<4:2>)
- T1IS<1:0> (IPC1<1:0)

Setting Timer1 interrupt priority level = 0 effectively disables the timer's ability to generate an interrupt.

In addition to enabling the Timer1 interrupt, an Interrupt Service Routine, ISR, is generally required. Below is a partial code example of an ISR.

Note: It is the user's responsibility to clear the corresponding interrupt flag bit before returning from an ISR.

EXAMPLE 13-5: TIMER INTERRUPT AND PRIORITIES

```
T1CON = 0 \times 0
                         // Stop the Timer and Reset Control register
                         // Set prescaler at 1:1, internal clock source
                         // Clear timer register
TMR1 = 0 \times 0:
PR1 = 0xFFFF;
                         // Load period register
                       // Set priority level=3
IPC1SET = 0 \times 000C;
IPC1SET = 0 \times 0001;
                        // Set subpriority level=1
                         // Could have also done this in single
                         // operation by assigning IPC1SET = 0x000D
IFSOCLR = 0 \times 0010;
                        // Clear Timer interrupt status flag
                        // Enable Timer interrupts
TECOSET = 0 \times 0010;
T1CONSET = 0 \times 8000;
                        // Start Timer
```

EXAMPLE 13-6: TIMER ISR

```
void __ISR(TIMER_1_VECTOR, IPL3) T1_Interrupt_ISR(void)
{
    ... perform application specific operations in response to the interrupt
    IFSOCLR = 0x0010; // Be sure to clear the Timer 1 interrupt status
}
```

Note: The timer ISR code example shows MPLAB[®] C32 C Compiler specific syntax. Refer to your compiler manual regarding support for ISRs.

13.6 I/O Pin Configuration

Table 13-4 provides a summary of I/O pin resources associated with Timer1. The table shows the settings required to make each I/O pin work with a specific timer module.

TABLE 13-4: I/O PIN CONFIGURATION FOR USE WITH THE TIMER MODULE

		Required Settings for Module Pin Control					
I/O Pin Name	Required	Module Enable ⁽²⁾	Bit Field ⁽²⁾	TRIS	Pin Type	Buffer Type	Description
T1CK	Yes ⁽¹⁾	ON	TCS, TGATE	Input	Ι	ST	Timer1 External Clock/Gate Input

CMOS = CMOS compatible input or output ST = Schmitt Trigger input with CMOS levels I = Input O = Output

Note 1: This pin is only required for Gated Timer or External Synchronous Clock modes. Otherwise, this pin can be used for general purpose I/O and requires the user to set the corresponding TRIS control register bits.

2: This bit is located in the T1CON register.

PIC32MX3XX/4XX

NOTES:

14.0 TIMERS 2, 3, 4, 5

Note:	This data sheet summarizes the features of									
	the PIC32MX3XX/4XX family of devices. It									
	is not intended to be a comprehensive refer-									
	ence source. Refer to the "PIC32MX Family									
	Reference Manual" (DS61132) for a									
	detailed description of this peripheral.									

This family of PIC32MX3XX/4XX devices feature four synchronous 16-bit timers (default) that can operate as a free-running interval timer for various timing applications and counting external events. The following modes are supported:

- Synchronous Internal 16-Bit Timer
- Synchronous Internal 16-Bit Gated Timer
- Synchronous External 16-Bit Timer

Two 32-bit synchronous timers are available by combining Timer2 with Timer3 and Timer4 with Timer5. The 32-bit timers can operate in three modes:

- · Synchronous Internal 32-Bit Timer
- Synchronous Internal 32-Bit Gated Timer
- Synchronous External 32-Bit Timer

Note:	Throughout this chapter, references to
	registers TxCON, TMRx, and PRx use 'x'
	to represent Timer2 through 5 in 16-bit
	modes. In 32-bit modes, 'x' represents
	Timer2 or 4; 'y' represents Timer3 or 5.

TABLE 14-1:	TIMER FEATURES

14.1 Additional Supported Features

- Selectable clock prescaler
- · Timers operational during CPU IDLE
- Time base for input capture and output compare modules (Timer2 and Timer3 only)
- ADC event trigger (Timer3 only)
- Fast bit manipulation using CLR, SET and INV registers

Table 14-1 highlights the available features of these timers.

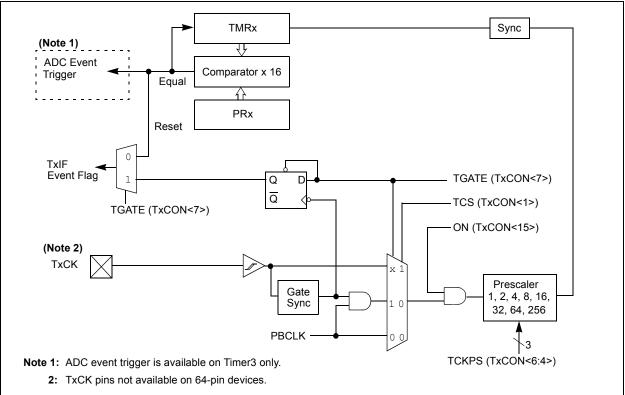

Timers	Low-Power Oscillator	Asynchronous External Clock	16-Bit Synchronous Timer	32-Bit Synchronous Timer ⁽¹⁾	Gated Timer	Special Event Trigger
2, 4	No	No	Yes	Yes	Yes	No
3, 5	No	No	Yes	Yes	Yes	Yes ⁽²⁾

Note 1: 32-bit mode requires combining timers 2 and 3 or timers 4 and 5.

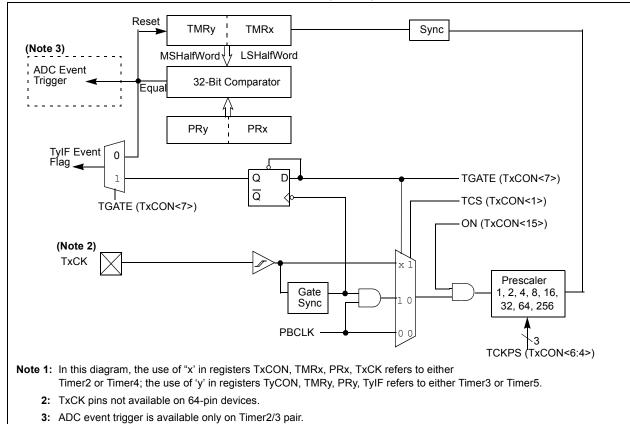

2: ADC event trigger supported by Timer3 only.

- bit 1 **TCS:** Timer Clock Source Select bit 1 = External clock from TxCK pin
 - 0 = Internal peripheral clock
- bit 0 Reserved: Maintain as '0'; ignore read

14.3 Modes of Operation

The 16-bit (default) and 32-bit mode timer peripherals can operate as synchronous timer/counters using internal or external clock sources, or as synchronous gated timers using an internal clock source and external clock/gate pins. Each mode is easily configured and described in the following sections.

14.3.1 CONSIDERATIONS FOR ALL TIMER MODES

- A timer module is disabled and powered off when the ON bit (TxCON<15>) = 0, thus providing maximum power savings. All other TxCON bits remain unchanged.
- Updates to the TxCON register should only be performed when the timer module is disabled, ON bit (TxCON<15>) = 0.
- A timer continues operating when the CPU goes into Idle mode if the "Stop In Idle mode" control bit is disabled, SIDL (TxCON<13>) bit = 0. If enabled, SIDL = 1, the timer module stops operation while the CPU is in Idle mode.
- Setting or clearing the ON bit (TxCON<15>) and any other bits in the TxCON register during a single instruction may cause undefined behavior. The user is advised to program the TxCON register with the desired settings with one instruction, and then set the ON bit in a subsequent instruction.

14.3.2 SYNCHRONOUS INTERNAL 16-BIT TIMER

In this mode, the timer clock source is the internal PBCLK (Peripheral Bus Clock), TCS (TxCON<1>) = 0. The 16-bit TMRx Count register increments on every internal PBCLK cycle when the timer clock prescale <TCKPS> is 1:1.

The timer generates a timer match event after the TMRx Count register matches the PRx Period register value, then resets to 0x0000 on the next PBCLK clock cycle. The timer continues to increment and repeat the period match until the timer is disabled. For further details regarding timer events and interrupts, see **Section 14.4 Timer Interrupts**.

For clock prescale = N (other than 1:1), the timer operates at a clock rate = (PBCLK/N); therefore, the TMRx Count register increments on every Nth PBCLK clock cycle. For further details regarding timer prescaler, refer to **Section 14.3.9 Timer Clock Prescaler**. The following steps should be performed to properly configure the 16-bit Timer peripherals for Timer mode operation:

- 1. Clear ON control bit, (TxCON<15>) = 0, to disable timer.
- 2. Configure TCKPS control bits, (TxCON<6:4), to select desired timer clock prescale.
- 3. Set TCS control bit, (TxCON<1>) = 0, to select the internal PBCLK clock source.
- 4. Clear TMRx register.
- 5. Load PRx register with desired 16-bit match value.
- 6. If timer interrupts are to be used, refer to **Section 14.4 Timer Interrupts** for interrupt configuration steps.
- 7. Set ON control bit = 1 to enable Timer.

EXAMPLE 14-1: SYNCHRONOUS INTERNAL 16-BIT TIMER INITIALIZATION

$T2CON = 0 \times 0;$	//Stop and Init Timer
$TMR2 = 0 \times 0;$	//Clear timer register
<pre>PR2 = 0xFFFF;</pre>	//Load period register
T2CONSET = 0x8000	; // Start Timer

14.3.3 SYNCHRONOUS EXTERNAL 16-BIT TIMER

In this mode, the timer clock source is an external clock source or pulse applied to the TxCK pin, TCS (TxCON<1>) = 1. The 16-bit TMRx Count register increments on every rising edge of an external clock when the timer clock prescale <TCKPS> is 1:1.

Note: TxCK pins not available on 64-pin devices.

The timer generates a timer match event after the TMRx Count register matches the PRx register value, then resets to 0x0000 on the next external clock cycle. The timer continues to increment and repeat the period match until the timer is disabled. For further details regarding timer events and interrupts, see **Section 14.4 Timer Interrupts**.

For clock prescale = N (other than 1:1), the timer operates at a clock rate = (external clock/N); therefore, the TMRx Count register increments on every Nth external clock cycle. For further details regarding the timer prescaler, refer to **Section 14.3.9 Timer Clock Prescaler**. The following steps should be performed to properly configure the timer peripheral for Synchronous Counter mode operation:

- 1. Clear control bit, ON (TxCON<15>) = 0, to disable timer.
- 2. Select the desired timer prescaler using bits, TCKPS<2:0> (TxCON<6:4).
- Set control bit, TCS (TxCON<1>) = 1, to select an external clock source.
- 4. Clear Timer register, TMRx.
- 5. Load Period register, PRx, with desired 16-bit match value.
- 6. If timer interrupts are used, refer to **Section 14.4 Timer Interrupts** for interrupt configuration steps.
- 7. Set control bit, ON (TxCON<15>) = 1, to enable timer.

EXAMPLE 14-2: SYNCHRONOUS EXTERNAL 16-BIT TIMER INITIALIZATION

$T3CON = 0 \times 0;$	//Stop and Init Timer
T3CONSET = 0×0072 ;	//Prescaler=1:256, //external clock
$TMR3 = 0 \times 0;$	//Clear timer register
PR3 = 0x3FFF;	//Load period register
T3CONSET = 0x8000;	//Start Timer

14.3.4 SYNCHRONOUS INTERNAL 16-BIT GATED TIMER

In this mode, the timer clock source can only be the internal PBCLK (Peripheral Bus Clock), TCS (TxCON<1>) = 0. The TxCK pin provides the gating mechanism to enable and disable the timer counting, TGATE (TxCON<7>) = 1. The 16-bit TMRx Count register is enabled on the rising edge of the TxCK pin and increments on every internal PBCLK cycle when the timer clock prescale <TCKPS> is 1:1.

Note: TxCK pins not available on 64-pin devices.

The timer increments until the TMRx Count register matches the PRx register value. The TMRx Count register resets to 0x0000 on the next PBCLK clock cycle. A timer match event is not generated. The timer continues to increment and repeat the period match until the falling edge of the TxCK pin or the timer is disabled. On the falling edge of the gate signal, a timer gate event is generated and the TMRx Count register stops counting, but is not reset to 0x0000. The TMRx Count register must be reset in software. For further details regarding timer events and interrupts, see **Section 14.4 Timer Interrupts**. For clock prescale = N (other than 1:1), the timer operates at a clock rate = (PBCLK/N); therefore, the TMRx Count register increments on every Nth PBCLK clock cycle. For further details regarding timer prescaler, refer to **Section 14.3.9 Timer Clock Prescaler**.

The following steps should be performed to properly configure the timer peripheral for Gated Timer mode operation:

- 1. Clear control bit, ON (TxCON<15>) = 0, to disable Timer.
- 2. Select the desired timer prescaler using bits, TCKPS<2:0> (TxCON<6:4>).
- 3. Set control bit, TCS (TxCON<1>) = 0, to select the internal clock source.
- 4. Set control bit, TGATE (TxCON<7>) = 1.
- 5. Clear Timer register, TMRx.
- 6. Load Period register, PRx, with desired 16-bit match value.
- 7. If timer interrupts are to be used, refer to **Section 14.4 Timer Interrupts** for interrupt configuration steps.
- 8. Set control bit, ON (TxCON<15>) = 1, to enable timer.

EXAMPLE 14-3: SYNCHRONOUS INTERNAL 16-BIT GATED TIMER INITIALIZATION

$T4CON = 0 \times 0;$	//Stop and Init Timer
$T4CON = 0 \times 00E0;$	<pre>//Enable gated mode, //prescaler=1:64, //internal clock</pre>
TMR4 = 0;	//Clear timer register
PR4 = 0xFFFF;	//Load period register
$T4CONSET = 0 \times 8000$;//Start Timer

14.3.5 SYNCHRONOUS INTERNAL 32-BIT TIMER

In this mode, T32 (TxCON<3>) = 1 and the timer clock source is the internal PBCLK (Peripheral Bus Clock), TCS (TxCON<1>) = 0. The 32-bit TMRxy Count register increments on every internal PBCLK cycle when the timer clock prescale <TCKPS> is 1:1.

The timer generates a timer match event after the TMRxy Count register matches the PRxy Period register value, then resets to 0x00000000 on the next PBCLK clock cycle. The timer continues to increment and repeat the period match until the timer is disabled. For further details regarding timer events and interrupts, see Section 14.4 Timer Interrupts.

© 2008 Microchip Technology Inc.

For clock prescale = N (other than 1:1), the timer operates at a clock rate = (PBCLK/N); therefore, the TMRxy Count register increments on every Nth PBCLK clock cycle. For further details regarding the timer prescaler, refer to **Section 14.3.9 Timer Clock Prescaler**.

14.3.6 CONSIDERATIONS

- 32-bit timer pairs can be created using Timer2 with Timer3, or Timer4 with Timer5.
- With Timer2 or Timer4 enabled, setting the T32 bit (T2CON<3> or T4CON<3>) = 1 automatically enables the corresponding Timer3 or Timer5 module. For this reason, it is not necessary to manually enable Timer3 or Timer5.
- T2CON and T4CON control registers are used for configuring the 32-bit timer operations; Writes to T3CON and T5CON are ignored.
- T2CK and T4CK input pins are utilized for the 32bit gated timer or external synchronous counter operations; T3CK and T5CK are ignored.
- 32-bit timer interrupts use Timer3 or Timer5 interrupt enable bits and interrupt flag bits; Timer2 and Timer4 interrupt enable and interrupt flag bits are ignored.
- Load TMRxy pair by writing the 32-bit value to TMRx.
- Load PRxy pair by writing the 32-bit value to PRx.

The following steps should be performed to properly configure the 32-bit timer peripherals for Timer mode operation.

- 1. Clear control bit, ON (TxCON<15>) = 0, to disable timer.
- 2. Set control bit, T32 (TxCON<3>).
- 3. Select the desired timer prescaler using bits TCKPS<2:0> (TxCON<6:4>).
- 4. Set control bit, TCS (TxCON<1>) = 0, to select the internal clock source.
- 5. Clear Timer register, TMRxy.
- 6. Load Period register, PRxy, with desired 32-bit match value.
- 7. If timer interrupts are used, refer to **Section 14.4 Timer Interrupts** for interrupt configuration steps.
- 8. Set control bit, ON (TxCON<15>) = 1, to enable timer.

EXAMPLE 14-4: SYNCHRONOUS INTERNAL 32-BIT TIMER INITIALIZATION

	<pre>//Stop Timer4 and clear //Stop Timer5 and clear // Enable 32-bit mode, // prescaler at 1:8, // internal clock</pre>
$TMR4 = 0 \times 0;$	<pre>// Clear TMR4 and TMR5 // Same as TMR4 = 0x0</pre>
<pre>PR4 = 0xFFFFFFF;</pre>	<pre>// Load PR4 and PR5 // with 32-bit value</pre>
T4CONSET = 0x8000;	<pre>// Same as PR4=0xFFFFFFF // Start Timer</pre>

14.3.7 SYNCHRONOUS EXTERNAL 32-BIT TIMER

In this mode, T32 (TxCON<3>) = 1 and the timer clock source is an external clock source or pulse applied to the TxCK pin, TCS (TxCON<1>) = 1. The 32-bit TMRxy Count register increments on every synchronized rising edge of an external clock when the timer clock prescale <TCKPS> is 1:1.

Note: TxCK pins not available on 64-pin devices.

The timer generates a timer match event after the TMRxy Count register matches the PRxy register value, then resets to 0x00000000 on the next external clock cycle. The timer continues to increment and repeat the period match until the timer is disabled. For further details regarding timer events and interrupts, see **Section 14.4 Timer Interrupts**.

For clock prescale = N (other than 1:1), the timer operates at a clock rate = (external clock/N); therefore, the TMRxy Count register increments on every Nth external clock cycle. For further details regarding timer prescaler, refer to **Section 14.3.9 Timer Clock Prescaler**.

The following steps should be performed to properly configure the 32-bit timer peripheral for Synchronous Counter mode operation:

- Clear control bit, ON (TxCON<15>) = 0, to disable Timer.
- 2. Set control bit, T32 (TxCON<3>).
- 3. Select the desired timer prescaler using bits TCKPS<2:0> (TxCON<6:4>).
- 4. Set control bit, TCS (TxCON<1>) = 1, to select an external clock source.
- 5. Clear Timer register, TMRx.
- 6. Load Period register, PRx, with desired 32-bit match value.
- 7. If timer interrupts are used, refer to **Section 14.4 Timer Interrupts** for interrupt configuration steps.
- 8. Set control bit, ON (TxCON<15>) = 1, to enable timer.

EXAMPLE 14-5: SYNCHRONOUS EXTERNAL 32-BIT TIMER INITIALIZATION

T2CON = 0x0; //Stop Timer2 and clear
T3CON = 0x0; //Stop Timer3 and clear
T2CONSET = 0x006A //32-bit mode,
//external clock,
//prescale=1:64
TMR2 = $0x0$; // Clear TMR2 and TMR3
$// \text{Same as TMR2} = 0 \times 0$
PR2 = 0xFFFFFFFF; // Load PR2 and PR3
<pre>// Same as PR2=0xFFFFFFF</pre>
T2CONSET = 0x8000; // Start timer

14.3.8 SYNCHRONOUS INTERNAL 32-BIT GATED TIMER

In this mode, the timer clock source is the internal PBCLK (Peripheral Bus Clock), TCS (TxCON<1>) = 0. The TxCK pin provides the gating mechanism to enable and disable the timer counting, TGATE (TxCON<7>) = 1. The 32-bit TMRxy Count register is enabled on the rising edge of the TxCK pin and increments on every internal PBCLK cycle when the timer clock prescale <TCKPS> is 1:1.

Note: TxCK pins not available on 64-pin devices.

The timer increments until the TMRxy Count register matches the PRxy register value. The TMRxy Count register resets to 0x0000000 on the next PBCLK clock cycle. A timer match event is not generated. The timer continues to increment and repeat the period match until the falling edge of the TxCK pin or the timer is disabled. On the falling edge of the gate signal, a timer gate event is generated and the TMRxy Count register stops counting, but is not reset to 0x00000000. The TMRxy Count register must be reset in software. For further details regarding timer events and interrupts, see Section 14.4 Timer Interrupts.

For clock prescale = N (other than 1:1), the timer operates at a clock rate = (PBCLK/N); therefore, the TMRxy Count register increments on every Nth timer clock cycle. For further details regarding timer prescaler, refer to **Section 14.3.9 Timer Clock Prescaler**.

The following steps should be performed to properly configure the timer peripheral for Gated Timer mode operation:

- Clear control bit, ON (TxCON<15>) = 0, to disable timer.
- 2. Set control bit, T32 (TxCON<3>).
- 3. Select the desired timer prescaler using bits TCKPS<2:0> (TxCON<6:4>).
- 4. Set control bit, TCS (TxCON<1>) = 0, to select the internal clock source.
- 5. Set control bit, TGATE (TxCON<7>) = 1.
- 6. Clear Timer register, TMRx.

- 7. Load Period register, PRx, with desired 32-bit match value.
- 8. Set control bit, ON (TxCON<15>) = 1, to enable timer.

EXAMPLE 14-6: SYNCHRONOUS INTERNAL 32-BIT GATED TIMER INITIALIZATION

$T4CON = 0 \times 0;$	//Stop Timer4 and clear
$T5CON = 0 \times 0;$	//Stop Timer5 and clear
$T4CONSET = 0 \times 00C8;$	//32-bit mode,
	//gate enable,
	//internal clock,
	//1:16 prescale
$TMR4 = 0 \times 0;$	//Clear TMR4 and TMR5
	//Same as TMR4 = 0x0
<pre>PR4 = 0xFFFFFFFF;</pre>	//Load PR4 and PR5 regs
	//Same as PR4 =0xFFFFFFFF
$T4CONSET = 0 \times 8000;$	//Start 32-bit timer

14.3.9 TIMER CLOCK PRESCALER

Timer clock prescale bits, TCKPS<1:0> (TxCON<6:4>), are used to divide the timer clock source permitting the TMR register to increment on every 1, 2, 4, 8, 16, 32, 64, or 256 (PBCLK or external) clock cycles. For example, if the clock prescale is 1:8, then the timer increments on every 8th timer clock cycle.

14.3.10 CONSIDERATIONS

Associated with the clock prescale selection bits is a prescale counter. The timer prescale counter is cleared when any of the following conditions occur:

- 1. Any device Reset, except a Power-on Reset.
- 2. The timer is disabled.
- 3. Any write to the TMR register.

Note:	When the timer clock source is external and
	the timer clock prescale = N (other than
	1:1), 2 to 3 external clock cycles are
	required to reset and synchronize the
	prescaler.

- When the timer clock source is external and the timer clock prescale = N (other than 1:1), 2 to 3 external clock cycles are required, after the timer ON bit is set = 1, before the TMRx Count register increments.
- After a timer match event (TMRx = PRx) and depending on the timer clock prescale setting N (other than 1:1), the timer will require N additional (PBCLK or external) clock cycles before the TMRx Counter register resets to 0x0000. Reading the TMRx Count register just after the timer match event, but before the TMRx Count register is reset, will return the timer match value.

14.4 Timer Interrupts

A timer can generate an interrupt on a period match event or a gate event, caused by the falling edge of the external gate signal.

A timer sets its corresponding interrupt flag bit, TxIF, whenever the timer event is generated. Refer to a specific timer mode for details regarding these event conditions. When a timer event is generated, the interrupt flag bit is set within 1 PBCLK + 2 SYSCLK cycles. If the timer interrupt enable bit is set, TxIE = 1, an interrupt is generated.

The timer module is enabled as a source of interrupts via the respective Timer Interrupt Enable bit, TxIE (IECx<n>). The Timer Interrupt Flag, TxIF (IFSx<n>), must be cleared in software.

The interrupt priority level bits and interrupt subpriority level bits must be also be configured:

- TxIP<2:0> (IPCx<4:2>)
- TxIS<1:0> (IPCx<1:0)

Setting the timer's interrupt priority level = 0 effectively disables the timer's ability to generate an interrupt.

In addition to enabling the timer interrupt, an Interrupt Service Routine, ISR, is required. Example 14-7 through Example 14-9 show a partial code example of an ISR.

EXAMPLE 14-7: 16-BIT TIMER INTERRUPT AND PRIORITIES

T2CON = 0x0;	<pre>// Stop Timer and clear control register, // prescaler at 1:1,internal clock source</pre>
<pre>TMR2 = 0x0; PR2 = 0xFFFF;</pre>	// Clear timer register // Load period register
	<pre>// Set priority level=3 // Set subpriority level=1 // Could have also done this in single // operation by assigning IPC2SET = 0x000000D</pre>
	// Clear Timer interrupt status flag // Enable Timer interrupts
T2CONSET = 0x8000;	// Start Timer

EXAMPLE 14-8: 32-BIT TIMER INTERRUPT AND PRIORITIES

$T4CON = 0 \times 0;$	
$T5CON = 0 \times 0;$	// Stop 16-bit Timer5 and clear control register
$T4CONSET = 0 \times 0038;$	<pre>// Enable 32-bit mode, prescaler at 1:8,</pre>
	// internal clock source
$TMR4 = 0 \times 0;$	// Clear contents of the TMR4 and TMR5
	// registers in one 32-bit load operation
<pre>PR4 = 0xFFFFFFFF;</pre>	// Load PR4 and PR5 registers with 32-bit value
	// 0xFFFFFFFF in one 32-bit load operation
IPC5SET = 0x0000004;	<pre>// Set priority level=1 and</pre>
IPC5SET = 0x0000001;	// Set subpriority level=1
	// Could have also done this in single
	<pre>// operation by assigning IPC5SET = 0x00000005</pre>
$IFSOCLR = 0 \times 10000000;$	// Clear the Timer5 interrupt status flag
IECOSET = 0x1000000;	// Enable Timer5 interrupts
$T4CONSET = 0 \times 8000;$	// Start Timer

EXAMPLE 14-9: **TIMER ISR**

```
void ISR(TIMER 2 VECTOR, ipl3) T2 Interrupt ISR(void)
   ... perform application specific operations in response to the interrupt
   IFSOCLR = 0x00000100; // Be sure to clear the Timer2 interrupt status
```

The timer ISR code example shows MPLAB[®] C32 Compiler specific syntax. Refer to your compiler manual Note: regarding support for ISRs.

14.4.1 I/O Pin Configuration

The table below provides a summary of I/O pin resources associated with the timer modules. The table shows the settings required to make an I/O pin available for a specific Timer module.

		-	Settings for I Pin Control	Module				
I/O Pin Name	Required	Module Enable ⁽²⁾			Pin Type	Buffer Type	Description	
T2CK	Yes ⁽¹⁾	ON	TCS, TGATE	Input	Ι	ST	Timer2 External Clock/Gate Input	
ТЗСК	Yes ¹⁾	ON	TCS, TGATE	Input	Ι	ST	Timer3 External Clock/Gate Input	
T4CK	Yes ⁽¹⁾	ON	TCS, TGATE	Input	I	ST	Timer4 External Clock/Gate Input	
T5CK	Yes ⁽¹⁾	ON	TCS, TGATE	Input	I	ST	Timer5 External Clock/Gate Input	

TABLE 14-2: I/O PIN CONFIGURATION FOR USE WITH TIMER MODULES

Legend:

CMOS = CMOS compatible input or output I = Input O = Output

ST = Schmitt Trigger input with CMOS levels

- Note 1: These pins are only required for modes using gated timer or external clock inputs. Otherwise, these pins can be used for general purpose I/O and require the user to set the corresponding TRIS register bits. TxCK pins not available on 64-pin devices.
 - 2: These bits are located in the TxCON register.

PIC32MX3XX/4XX

NOTES:

15.0 INPUT CAPTURE

Note:	This data sheet summarizes the features of
	the PIC32MX3XX/4XX family of devices. It
	is not intended to be a comprehensive refer-
	ence source. Refer to the "PIC32MX Family
	Reference Manual" (DS61132) for a
	detailed description of this peripheral.

The input capture module is useful in applications requiring frequency (period) and pulse measurement. The PIC32MX3XX/4XX devices support up to five input capture channels.

The input capture module captures the 16-bit or 32-bit value of the selected Time Base registers when an event occurs at the ICx pin. The events that cause a capture event are listed below in three categories:

- 1. Simple Capture Event modes
 - Capture timer value on every falling edge of input at ICx pin
 - Capture timer value on every rising edge of input at ICx pin
- 2. Capture timer value on every edge (rising and falling)

- 3. Capture timer value on every edge (rising and falling), specified edge first.
- 4. Prescaler Capture Event modes
- Capture timer value on every 4th rising edge of input at ICx pin
- Capture timer value on every 16th rising edge of input at ICx pin

Each input capture channel can select between one of two 16-bit timers (Timer2 or Timer3) for the time base, or two 16-bit timers (Timer2 and Timer3) together to form a 32-bit timer. The selected timer can use either an internal or external clock.

Other operational features include:

- Device wake-up from capture pin during CPU Sleep and Idle modes
- Interrupt on input capture event
- 4-word FIFO buffer for capture values
- Interrupt optionally generated after 1, 2, 3 or 4 buffer locations are filled
- Input capture can also be used to provide additional sources of external interrupts

REGISTER 15-2: ICxBUF: INPUT CAPTURE x BUFFER REGISTER

bit 31-0 ICxBUF<31:0>: Buffer Register bits Value of the current captured input timer count

15.1 Timer Selection

The input capture module can select between one of two 16-bit timers for the time base, or two 16-bit timers together to form a 32-bit timer. Setting ICTMR (ICxCON<7>) to '0' selects the Timer3 for capture. Setting ICTMR (ICxCON<7>) to 1 selects the Timer2 for capture.

An input capture channel configured to support 32-bit capture, may use a 32-bit timer resource for capture. By setting ICC32 (ICxCON<8>) to '1', a 32-bit timer resource is captured. The 32-bit timer resource is routed into the module using the existing 16-bit timer inputs.

The timers clock can be setup using the internal peripheral clock source, or using a synchronized external clock source applied at the TxCK pin.

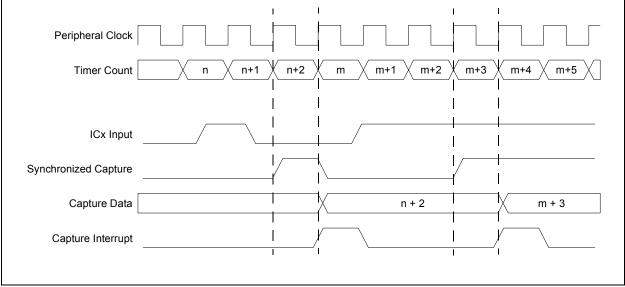

15.2 Simple Capture Event Modes

These modes are specified by setting the ICM (ICxCON<2:0>) bits to '010', '011', or '110'. Setting ICM = '011' configures the module to capture the timer value on any rising edge of the capture input. ICM = '010' configures the module to capture the timer on any falling edge of the capture input. Setting ICM = '110' configures the channel to capture the timer on every transition of the capture input, beginning with the edge specified by ICFEDGE (ICxCON<9>). In Simple Capture Event mode, the prescaler is not used. See Figure 15-2 for simplified timing diagrams of a simple capture event.

Note: Since the capture input must be synchronized to the peripheral clock, the module captures the timer count value, which is valid 2-3 peripheral clock cycles (TPB) after the capture event.

An input capture interrupt event is generated after one, two, three or four timer count captures, as configured by ICI (ICxCON<6:5>).

FIGURE 15-2: SIMPLE CAPTURE EVENT TIMING DIAGRAM CAPTURE EVERY RISING EDGE

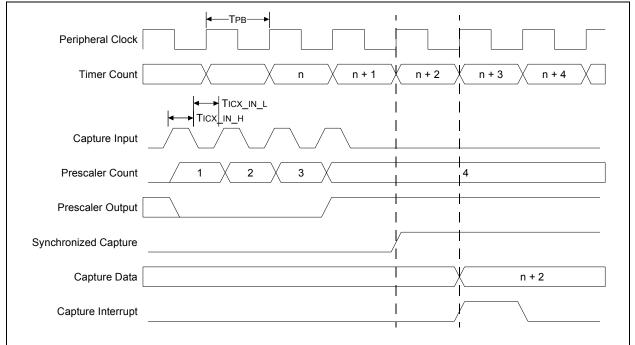

15.3 Prescaled Capture Event Modes

In Prescaled Capture Event mode, the input capture module triggers a capture event on either every fourth or every sixteenth rising edge. These modes are selected by setting the ICM (ICxCON<2:0>) bits to '100' or '101', respectively.

Note: Since the capture input must be synchronized to the peripheral clock, the timer count value is captured, which is valid 2-3 peripheral clock periods after the capture event. Note: It is recommended that the user disable (i.e., clear ON bit, ICxCON<15>) the capture module before switching to Prescaler Capture Event mode. Simply switching to Prescaler Capture Event mode from another active mode does not reset the prescaler and may cause an inadvertent capture event.

Figure 15-3 depicts a capture event when the input capture module is in Prescaler Capture Event mode.

FIGURE 15-3: PRESCALER CAPTURE EVENT TIMING DIAGRAM

15.4 Edge Detect (Hall Sensor) Mode

In Edge Detect mode, the input capture module captures a timer count value on every edge of the capture input. Edge Detect mode is selected by setting the ICM bit to '001'. In this mode, the capture prescaler is not used and the capture overflow bit, ICOV (ICxCON<4>) is not updated. In this mode, the Interrupt Control bits (ICI, ICxCON<6:5>) are ignored and an interrupt event is generated for every timer count capture

15.5 Interrupt Only Mode

When the Input Capture module is set for Interrupt Only mode (ICM = '111') and the device is in Sleep or Idle mode, the capture input functions as an interrupt pin. Any rising edge on the capture input triggers an interrupt. No timer values are captured and the FIFO buffer is not updated. When the device leaves Sleep or Idle mode, the interrupt signal is deasserted.

In this mode, since no timer values are captured, the Timer Select bit ICTMR (ICxCON<7>) is ignored and there is no need to configure the timer source. A wakeup interrupt is generated on the first rising edge, therefore the Interrupt Control bits ICI (ICxCON<6:5>) are also ignored. The prescaler is not used in this mode.

EXAMPLE 15-1: INPUT CAPTURE EXAMPLE CODE

```
/*
The following code segment initialized the timer and setup the input capture
module.
*/
     . . .
    //Initialize timer 2
    T2CON = 0x0 // Stop and Init Timer
TMR2 = 0x0; // Clear timer register
PR2 = 0x7000; // Load period register
    T2CONSET = 0x8000;// Start Timer
    // Init IC1 module
    IC1CON = 0x8081;//Enable Module, use timer 2,
                      //Capture mode 1 (capture every edge)
     . . .
    //Read the capture data if available
    int cap data;
     while( IC1CONbits.ICBNE ) // while data available in capture FIFO
     {
        cap_data = IC1BUF;
         ... //process data
     }
     . . .
```

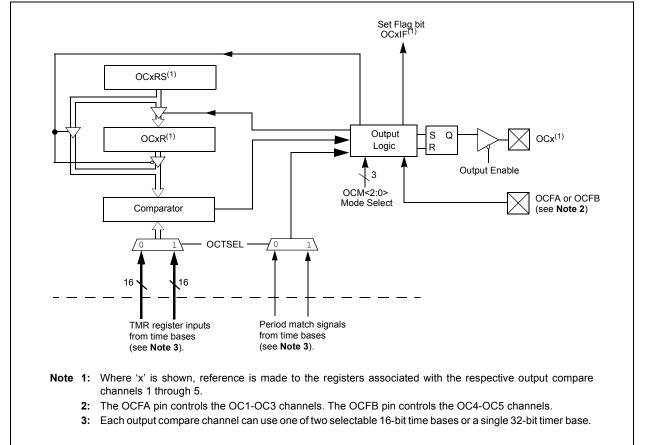

16.0 OUTPUT COMPARE

Note:	This data sheet summarizes the features of
	the PIC32MX3XX/4XX family of devices. It
	is not intended to be a comprehensive refer-
	ence source. Refer to the "PIC32MX Family
	Reference Manual" (DS61132) for a
	detailed description of this peripheral.

The Output Compare module (OCMP) is used to generate a single pulse or a train of pulses in response to selected time base events. For all modes of operation, the OCMP module compares the values stored in the OCxR and/or the OCxRS registers to the value in the selected timer. When a match occurs, the OCMP module generates an event based on the selected mode of operation. The following are some of the key features:

- · Multiple output compare modules in a device
- Programmable interrupt generation on compare event
- Single and Dual Compare modes
- Single and continuous output pulse generation
- Pulse-Width Modulation (PWM) mode
- Hardware-based PWM Fault detection and automatic output disable
- Programmable selection of 16-bit or 32-bit time bases.
- Can operate from either of two available 16-bit time bases or a single 32-bit time base.

16.1 Setup for Single Output Change

There are three modes of operation that change the state of the output pin; these modes can be referred to as drive high, drive low and toggle. The configuration for these modes is identical, the mode is selected by the OCM bits. For this example, Tx will represent Timer2.

Drive High: When the OCM control bits (OCxCON<2:0>) are set to '001', the selected output compare channel initializes the OCx pin to the low state and drives the output pin high when a compare event occurs.

Drive Low: When the OCM control bits (OCxCON<2:0>) are set to '010', the selected output compare channel initializes the OCx pin to the high state and drives the output pin low when a compare event occurs.

Toggle: When the OCM control bits (OCxCON<2:0>) are set to '011', the selected output compare channel OCx pin is not initialized. The OCx pin is driven to the opposite state when a compare event occurs.

To generate a output change signal, the following steps are required (these steps assume the timer source is initially turned off, but this is not a requirement for the module operation):

- Determine the timer clock cycle time. Take into account the frequency of the external clock to the timer source (if one is used) and the timer prescaler settings.
- 2. Calculate time to the rising edge of the output pulse relative to the timer start value (0000h).
- 3. Determine if the output compare module will be used in 16 or 32-bit mode based on the previous calculations.
- Configure the timer to be used as the time base for 16 or 32-bit mode by writing to the T32 bit (TxCON<T32>).
- Configure the output compare channel for 16 or 32-bit operation by writing to the OC32 bit (OCxCON<5>).
- 6. Write the value computed in step 2 above into the Compare register, OCxR.
- 7. Set Timer Period register, PRx, to the value equal to or greater than the value in OCxRS, the Secondary Compare register.
- Set the OCM bits to the desired mode of operation and the OCTSEL (OCxCON<3>) bit to the desired timer source. The OCx pin state will now be driven low.
- 9. Set the ON (TxCON<15>) bit to '1' which enables the compare time base to count.
- 10. Upon the first match between TMRx and OCxR, the OCx pin will be driven high.

- 11. When the incrementing timer, TMRx, matches the Secondary Compare register, OCxRS, the second and trailing edge (high-to-low) of the pulse is driven onto the OCx pin. No additional pulses are driven onto the OCx pin and it remains at low. As a result of the second compare match event, the OCxIF interrupt flag bit is set, which will result in an interrupt if it is enabled, by setting the OCxIE bit. For further information on peripheral interrupts, refer to **Section 8.0** "Interrupts".
- 12. To initiate another single pulse output, change the Timer and Compare register settings, if needed, and then issue a write to set the OCM bits to the desired mode of operation. Disabling and reenabling of the timer and clearing the Timer register are not required, but may be advantageous for defining a pulse from a known event time boundary.

16.2 Setup for Single Output Pulse Generation

When the OCM control bits (OCxCON<2:0>) are set to '100', the selected output compare channel initializes the OCx pin to the low state and generates a single output pulse.

To generate a single output pulse, the following steps are required (these steps assume the timer source is initially turned off, but this is not a requirement for the module operation): For this example Tx will represent Timer2.

- Determine the timer clock cycle time. Take into account the frequency of the external clock to the timer source (if one is used) and the timer prescaler settings.
- 2. Calculate time to the rising edge of the output pulse relative to the timer start value (0000h).
- 3. Calculate the time to the falling edge of the pulse based on the desired pulse width and the time to the rising edge of the pulse.
- 4. Determine if the output compare module will be used in 16 or 32-bit mode based on the previous calculations.
- 5. Configure the timer to be used as the time base for 16 or 32-bit mode by writing to the T32 bit (TxCON<T32>).
- Configure the output compare channel for 16 or 32-bit operation by writing to the OC32 bit (OCxCON<5>).
- 7. Write the values computed in steps 2 and 3 above into the Compare register, OCxR, and the Secondary Compare register, OCxRS, respectively.
- 8. Set Timer Period register, PRx, to the value equal to or greater than the value in the OCxRS, the Secondary Compare register.

- Set the OCM bits to '100' and the OCTSEL (OCxCON<3>) bit to the desired timer source. The OCx pin state will now be driven low.
- 10. Set the ON (TxCON<15>) bit to '1' which enables the compare time base to count.
- 11. Upon the first match between TMRx and OCxR, the OCx pin will be driven high.
- 12. When the incrementing timer matches the Secondary Compare register, OCxRS, the second and trailing edge (high-to-low) of the pulse is driven onto the OCx pin. No additional pulses are driven onto the OCx pin and it remains at low. As a result of the second compare match event, the OCxIF interrupt flag bit is set, which will result in an interrupt if it is enabled, by setting the OCxIE bit. For further information on peripheral interrupts, refer to Section 8.0 "Interrupts".
- 13. To initiate another single pulse output, change the Timer and Compare register settings, if needed, and then issue a write to set the OCM bits to '100'. Disabling and re-enabling of the timer and clearing the TMRx register are not required, but may be advantageous for defining a pulse from a known event time boundary.

EXAMPLE 16-1: EXAMPLE CODE

```
The following code example will set the Output Compare 1 module
// for interrupts on the single pulse event and select Timer 2
// as the clock source for the compare time base.
   T2CON = 0 \times 0010;
                                   // Configure Timer 2 for a prescaler of 2
   OC1CON = 0 \times 0000;
                                  // Turn off OC1 while doing setup.
   OC1CON = 0 \times 0004;
                                   // Configure for single pulse mode
                                  // Initialize primary Compare Register
   OC1R = 0x3000;
   OC1RS = 0x3003;
                                  // Initialize secondary Compare Register
                                  // Set period (PR2 is now 32-bits wide)
   PR2 = 0x3003;
                                  // configure int
                                  // Clear the OC1 interrupt flag
   TFOCLR = 0 \times 00000080;
                                  // Enable OC1 interrupt
   IEOSET = 0 \times 00000080;
   IPC1SET = 0 \times 0030000;
                                  // Set OC1 interrupt subpriority to 3,
                                   // the highest level
                                   // Set subpriority to 3, maximum
   IPC1SET = 0 \times 00000003;
   T2CONSET = 0 \times 8000;
                                   // Enable timer2
   OC1CONSET = 0 \times 8000;
                                   // Enable the OC1 module
   // Example code for Output Compare 1 ISR:
#pragma interrupt OC1IntHandler ipl4 vector 6
void CmpIntHandler(void)
{
   // insert user code here
   IFSOCLR = 0x00000080; // Clear the OC1 interrupt flag
}
```

16.3 Setup for Continuous Output Pulse Generation

When the OCM control bits (OCxCON<2:0>) are set to '101', the selected output compare channel initializes the OCx pin to the low state and generates output pulses on each and every compare match event.

For the user to configure the module for the generation of a continuous stream of output pulses, the following steps are required (these steps assume the timer source is initially turned off, but this is not a requirement for the module operation). For this example, Tx will represent Timer2.

- Determine the timer clock cycle time. Take into account the frequency of the external clock to the timer source (if one is used) and the timer prescaler settings.
- 2. Calculate time to the rising edge of the output pulse relative to the TMRx start value (0000h).
- 3. Calculate the time to the falling edge of the pulse based on the desired pulse width and the time to the rising edge of the pulse.
- 4. Determine if the output compare module will be used in 16 or 32-bit mode based on the previous calculations.
- 5. Configure the timer to be used as the time base for 16 or 32-bit mode by writing to the T32 bit (TxCON<T32>).
- Configure the output compare channel for 16 or 32-bit operation by writing to the OC32 bit (OCxCON<5>).
- 7. Write the values computed in step 2 and 3 above into the Compare register, OCxR, and the Secondary Compare register, OCxRS, respectively.
- 8. Set Timer Period register, PRx, to the value equal to or greater than the value in OCxRS, the Secondary Compare register.
- 9. Set the OCM bits to '101' and the OCTSEL bit to the desired timer source. The OCx pin state will now be driven low.
- 10. Enable the compare time base by setting the ON (TxCON<15>) bit to '1'.
- 11. Upon the first match between TMRx and OCxR, the OCx pin will be driven high.
- 12. When the compare time base, TMRy, matches the Secondary Compare register, OCxRS, the second and trailing edge (high-to-low) of the pulse is driven onto the OCx pin.
- 13. As a result of the second compare match event, the OCxIF interrupt flag bit set.
- 14. When the compare time base and the value in its respective Period register match, the TMRx register resets to 0x0000 and resumes counting.
- 15. Steps 8 through 11 are repeated and a continuous stream of pulses is generated, indefinitely. The OCxIF flag is set on each OCxRS-TMRx compare match event.

16.4 Pulse-Width Modulation Mode

There are two modes of PWM operation for this device: PWM and PWM with Fault input. The configuration of both modes is identical with the exception of the value written to the OCM bits to select the desired mode.

The following steps should be taken when configuring the output compare module for PWM operation:

- 1. Calculate the PWM period.
- 2. Calculate the PWM duty cycle.
- 3. Determine if the Output Compare module will be used in 16 or 32-bit mode based on the previous calculations.
- Configure the timer to be used as the time base for 16 or 32-bit mode by writing to the T32 bit (TxCON<T32>).
- Configure the output compare channel for 16 or 32-bit operation by writing to the OC32 bit (OCxCON<5>).
- 6. Set the PWM period by writing to the selected Timer Period register (PR).
- 7. Set the PWM duty cycle by writing to the OCxRS register.
- 8. Write the OCxR register with the initial duty cycle.
- 9. Enable interrupts, if required, for the timer and output compare modules. The output compare interrupt is required for PWM Fault pin utilization.
- Configure the output compare module for one of two PWM operation modes by writing to the Output Compare mode bits OCM<2:0> (OCxCON<2:0>).
- 11. Set the TMRx prescale value and enable the time base by setting ON (TxCON<15>) = 1.

Note: The OCxR register should be initialized before the output compare module is first enabled. The OCxR register becomes a read-only Duty Cycle register when the module is operated in the PWM modes. The value held in OCxR will become the PWM duty cycle for the first PWM period. The contents of the Duty Cycle Buffer register, OCxRS, will not be transferred into OCxR until a time base period match occurs.

16.4.1 PWM PERIOD

The PWM period is specified by writing to PR, the Timer Period register. The PWM period can be calculated using Equation 16-1.

EQUATION 16-1: CALCULATING THE PWM PERIOD

PWM Period = $[(PR+1) \cdot TPB \cdot (TMR Prescale Value)]$

PWM Frequency = 1/[PWM Period]

Note: A PRy value of N will produce a PWM period of N + 1 time base count cycles. For example, a value of 7 written into the PRy register will yield a period consisting of 8 time base cycles.

16.4.2 PWM DUTY CYCLE

The PWM duty cycle is specified by writing to the OCxRS register. The OCxRS register can be written to at any time, but the duty cycle value is not latched into OCxR until a match between the PR and timer occurs (i.e., the period is complete). This provides a double buffer for the PWM duty cycle and is essential for glitchless PWM operation. In the PWM mode, OCxR is a read-only register.

Some important boundary parameters of the PWM duty cycle include:

- If the Duty Cycle register, OCxR, is loaded with 0000h, the OCx pin will remain low (0% duty cycle).
- If OCxR is greater than PR (Timer Period register), the pin will remain high (100% duty cycle).
- If OCxR is equal to PR, the OCx pin will be low for one time base count value and high for all other count values.

See Example 16-2 for PWM mode timing details. Table 16-2 shows example PWM frequencies and resolutions for a device peripheral bus operating at 10 MHz.

EQUATION 16-2: CALCULATION FOR MAXIMUM PWM RESOLUTION

Maximum PWM Resolution (bits) =
$$\frac{\log_{10} \left(\frac{\text{FPB}}{\text{FPWM} \cdot \text{TMRy} \cdot \text{Prescaler}} \right)}{\log_{10}(2)} \text{bits}$$

EXAMPLE 16-2: PWM PERIOD AND DUTY CYCLE CALCULATION

Desired PWM frequency is 52.08 kHz, FPB = 10 MHz Timer 2 prescale setting: 1:1 $1/52.08 \text{ kHz} = (PR2 + 1) \cdot FBP \cdot (Timer2 \text{ prescale value})$ $19.20 \ \mu \text{s} = (PR2 + 1) \cdot 0.1 \ \mu \text{s} \cdot (1)$ PR2 = 191

Find the maximum resolution of the duty cycle that can be used with a 52.08 kHz PWM frequency and a 10 MHz peripheral bus clock rate.

Note: If the PR value exceeds 16 bits the module must be used in 32-bit mode to maintain the calculated PWM resolution. If reduced resolution is acceptable the Timer prescaler may be increased and the calculation repeated until the result is a 16-bit value. Increasing the Timer prescaler to allow operation in 16-bit mode may result in reduced PWM resolution.

EXAMPLE 16-3: PWM MODE PULSE SETUP AND INTERRUPT SERVICING (32-BIT MODE)

```
// The following code example will set the Output Compare 1 module
// for PWM mode with FAULT pin disabled, a 50% duty cycle and a
// PWM frequency of 52.08 kHz at FPB = 40 MHz. Timer2 is selected as
// the clock for the PWM time base and Output Compare 1 interrupts
// are enabled.
   OC1CON = 0 \times 0000;
                              // Turn off OC1 while doing setup.
   OC1R = 0 \times 00600000;
                             // Initialize primary Compare Register
   OC1RS = 0x00600000;
                             // Initialize secondary Compare Register
   OC1CON = 0 \times 0006;
                             // Configure for PWM mode, Fault pin Disabled
   PR2 = 0 \times 00600000;
                             // Set period
                              // configure int
   IFS0 &= ~0x0000080;
                             // Clear the OC1 interrupt flag
   IEC0 |= 0x0000080;
                             // Enable OC1 interrupt
   IPC1 |= 0x001C0000;
                              // Set OC1 interrupt priority to 7,
                              // the highest level
   IPC1 |= 0x0000003;
                             // Set subpriority to 3, maximum
   T2CON |= 0x8000;
                            // Enable timer2
   OC1CON |= 0x8000;
                            // turn on OC1 module
// Example code for Output Compare 1 ISR:
#pragma interupt OC1IntHandler ipl4 vector 36
void OC1IntHandler(void)
{
               // insert user code here
                  IFSOCLR = 0x00000080; // Clear the interrupt flag
}
```

16.5 Output Compare Register I/O Pin Control

When the output compare module is enabled, the I/O pin direction is controlled by the compare module. The compare module returns the I/O pin control back to the appropriate pin LAT and TRIS control bits when it is disabled.

When the PWM with Fault Protection Input mode is enabled, the OCFx Fault pin must be configured as an input by setting the respective TRIS SFR bit. The OCFx Fault input pin is not automatically configured as an input when PWM with Fault Input mode is selected.

Pin Name	Module Control	Controlling Bit Field	Required TRIS bit Setting	Pin Type	Buffer Type	Description
OC1	ON ⁽²⁾	OCM<2:0> ^(1,3)		D, O		Output Compare/PWM Channel 1
OC2	ON ⁽²⁾	OCM<2:0> ^(1,3)	—	D, O	_	Output Compare/PWM Channel 2
OC3	ON ⁽²⁾	OCM<2:0> ^(1,3)	—	D, O		Output Compare/PWM Channel 3
OC4	ON ⁽²⁾	OCM<2:0> ^(1,3)	—	D, O		Output Compare/PWM Channel 4
OC5	ON ⁽²⁾	OCM<2:0> ^(1,3)	—	D, O	_	Output Compare/PWM Channel 5
OCFA	ON ⁽²⁾	OCM<2:0> ^(1,3)	Input	D, I	ST	PWM Fault Protection A Input (For Channels 1-3) ⁽⁴⁾
OCFB	ON ⁽²⁾	OCM<2:0> ^(1,3)	Input	D, I	ST	PWM Fault Protection B Input (For Channels 4 -5) ⁽⁴⁾

TABLE 16-8:PINS ASSOCIATED WITH OUTPUT COMPARE MODULES 1-5

Legend: ST = Schmitt Trigger input with CMOS levels, I = Input, O = Output, A = Analog, D = Digital

Note 1: All pins are subject to device pin priority control.

2: ON (OCxCON<15>) = 1. When the module is turned off, pins controlled by the module are released.

3: Mode select bits OCM<2:0> (CMxCON<2:0>).

4: Use of PWM Fault input is optional and is controlled by the OCM bits.

NOTES:

17.0 SERIAL PERIPHERAL INTERFACE (SPI)

Note:	This data sheet summarizes the features of
	the PIC32MX3XX/4XX family of devices. It
	is not intended to be a comprehensive refer-
	ence source. Refer to the "PIC32MX Family
	Reference Manual" (DS61132) for a
	detailed description of this peripheral.

The Serial Peripheral Interface (SPI) module is a synchronous serial interface useful for communicating with external peripherals and other microcontroller devices. These peripheral devices may be Serial EEPROMs, shift registers, display drivers, A/D converters, etc. The PIC32MX3XX/4XX SPI module is compatible with Motorola[®] SPI and SIOP interfaces.

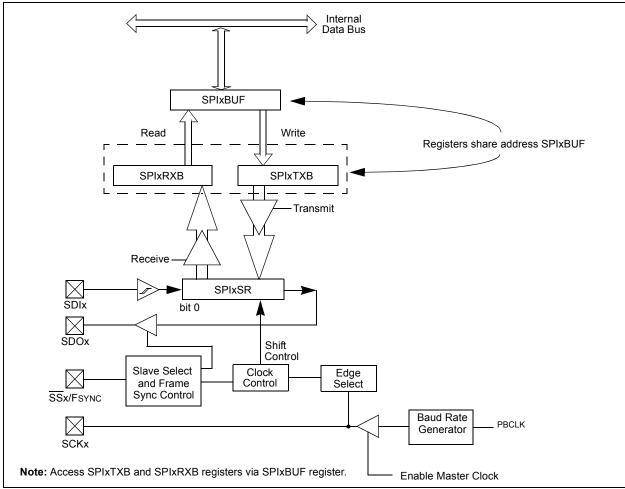

TABLE 17-1: SPI FEATURES

Following are some of the key features of this module:

- Master and Slave Modes Support
- Four Different Clock Formats
- Framed SPI Protocol Support
- User Configurable 8-Bit, 16-Bit and 32-Bit Data Width
- Separate SPI Data Registers for Receive and Transmit
- Programmable Interrupt Event on every 8-Bit, 16-Bit and 32-Bit Data Transfer
- Operation during CPU Sleep and Idle Mode
- Fast Bit Manipulation using CLR, SET and INV Registers

Available SPI Modes	SPI Master	SPI Slave	Frame Master	Frame Slave	8-Bit, 16-Bit and 32-Bit Modes	Selectable Clock Pulses and Edges	Selectable Frame Sync Pulses and Edges	Slave Select Pulse
Normal Mode	Yes	Yes	_		Yes	Yes	_	Yes
Framed Mode	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No

17.2 Master and Slave Modes

The PIC32MX3XX/4XX SPI module operates in normal Master or Slave modes and offers the following additional modes:

- · Framed Master
- Framed Slave
- 8, 16, 32-Bit Data Width Transfers
- Slave Select (Slave mode only)

Below is a typical system Master – Slave connection diagram.

17.2.1 8, 16, 32-BIT OPERATION

The PIC32MX3XX/4XX SPI module allows three types of data widths when transmitting and receiving data over an SPI bus. The selection of data width determines the minimum length of SPI data.

Two control bits, MODE32 and MODE16 (SPIxCON<11:10>), define the mode of operation. To change the mode of operation on the fly, the SPI module must be idle, i.e., not performing any transactions. If the SPI module is switched off (SPIxCON<15> = 0), the new mode will be available when the module is again switched on.

The number of clock pulses at the SCKx pin are dependent on the selected mode of operation. For 8-Bit mode, 8 clocks; for 16-Bit mode, 16 clocks; and for 32-Bit mode, 32 clocks are required.

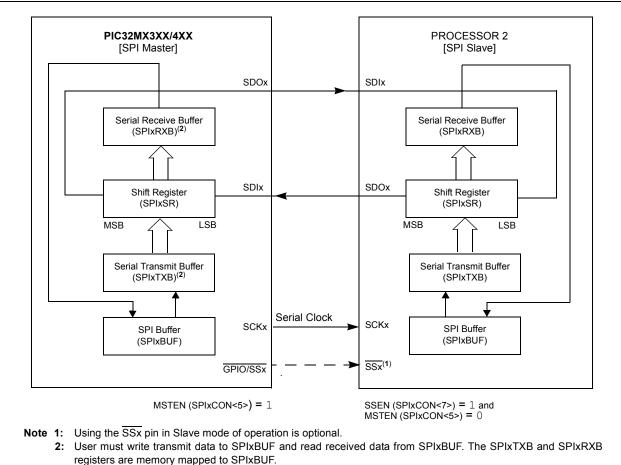

FIGURE 17-2: SPI MASTER/SLAVE CONNECTION

17.2.2 MASTER MODE

In Master mode, data from the SPIxBUF register is transmitted synchronously on the SDO (output) pin while synchronous data is received from the slave device on the SDI (input) pin. In this mode, the Master controls the synchronous data transfer with the SCK clock pin by generating 8, 16 or 32 clock pulses, depending on the selected data size.

17.2.2.1 Master Mode Operations

In Master mode the SCK and SDO pins are outputs and the SDI pin is an input. Setting the control bit, DISSDO (SPIxCON<12>), disables transmission at the SDO pin if Receive Only mode of operation is desired. Refer to Table 17-7.

The SDI (input) must be configured to properly sample the data received from the slave device by configuring the sample bit, SMP (SPIxCON<9>).

In Master mode, the SCK clock edge and polarity must be configured properly for the master and slave device to correctly transfer data synchronously. Refer to the timing diagram shown in Figure 17-3 to determine the appropriate settings.

In Master mode, the data transfers can be 8, 16, or 32 bits and are configured using control bits, MODE<32,16> (SPIxCON<11:10>). Refer to **Section 17.2.1 "8, 16, 32-Bit Operation"**.

In Master mode, the system clock is divided and then used as the serial clock. The division is based on the settings in the SPIxBRG register. Refer to Section 17.2.5 "SPI Master Mode Clock Frequency".

17.2.2.2 Master SPIxCON Configuration

The following bits must be configured as shown for the Master mode of operation when configuring the SPIxCON register:

- Enable Master Mode MSTEN (SPIxCON<5>) = 1.
- Disable Framed SPI support FRMEN (SPIxCON<31>) = 0

The remaining bits are shown with example configurations and may be configured as desired:

- Enable module control of SDO pin DISSDO (SPIxCON<12>) = 0
- Configure SCK clock polarity to idle high CKP (SPIxCON<6>) = 1
- Configure SCK clock edge transition from Idle to active – CKE (SPIxCON<8>) = 0
- Select 16-bit data width MODE<32,16> (SPIxCON<11:10>) = 01
- Sample data input at middle SMP (SPIxCON<9>) = 0
- Enable SPI module when CPU idle SIDL (SPIxCON<13>) = 0

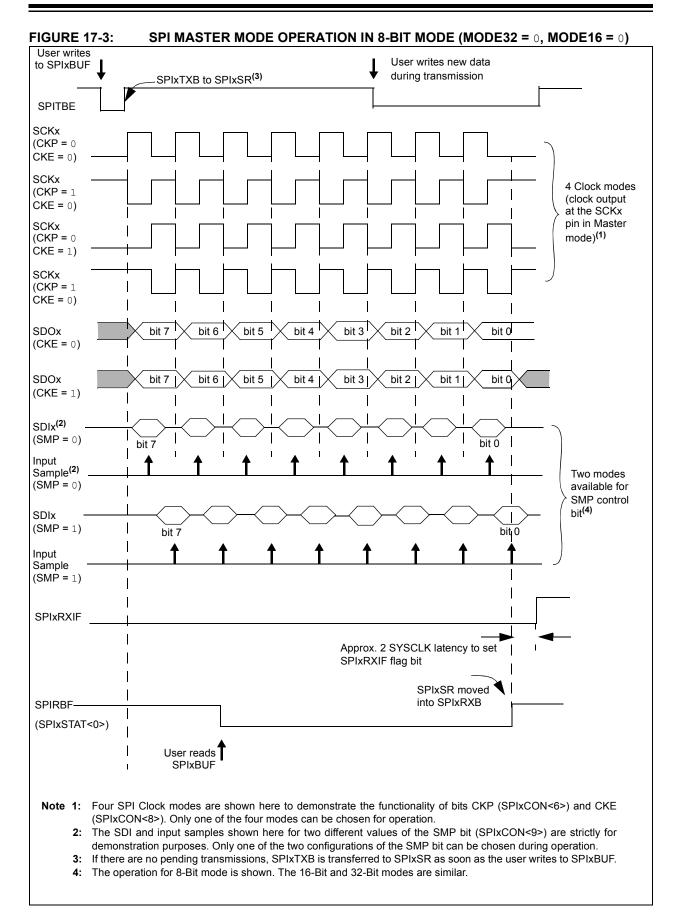

17.2.2.3 Master Mode Initialization

The following steps should be performed to setup the SPI module for the Master mode of operation:

- 1. If interrupts are used, disable the SPI interrupts in the respective IEC0/1 register.
- 2. Stop and reset the SPI module by clearing the ON bit.
- 3. Clear the receive buffer.
- 4. If interrupts are used, the following additional steps are performed:
 - Clear the SPIx interrupt flags/events in the respective IFS0/1 register.
 - Set the SPIx interrupt enable bits in the respective IEC0/1 register.
 - Write the SPIx interrupt priority and subpriority bits in the respective IPC5/7 register.
- 5. Write the Baud Rate register, SPIxBRG.
- 6. Clear the SPIROV bit (SPIxSTAT<6>).
- 7. Write the selected configuration settings to the SPIxCON register.
- Enable SPI operation by setting the ON bit (SPIxCON<15>).
- 9. Write the data to be transmitted to the SPIxBUF register. Transmission (and reception) will start as soon as data is written to the SPIxBUF register.

Note 1: When using the Slave Select mode, the SSx or another <u>GPIO</u> pin is used to control the slave's SSx input. The pin must be controlled in software.

- The user must turn off the SPI device prior to changing the CKE or CKP bits. Otherwise, the behavior of the device is not ensured.
- **3:** The SPI device must be turned off prior to changing the mode from Slave to Master.
- 4: The SPIxSR register cannot be written to directly by the user. All writes to the SPIxSR register are performed through the SPIxBUF register.

EXAMPLE 17-1: INITIALIZATION FOR 16-BIT SPI MASTER MODE

```
/*
   The following code example will initialize the SPI1 in master mode.
   It assumes that none of the SPI1 input pins are shared with an analog input.
   If so, the AD1PCFG and corresponding TRIS registers have to be properly configured.
*/
   int rData;
   IEC0CLR=0x03800000;
                                  // disable all interrupts
   SPI1CON = 0;
                                  // Stops and resets the SPI1.
                                 // clears the receive buffer
   rData=SPI1BUF;
   IFS0CLR=0x03800000;
                                 // clear any existing event
   IPC5CLR=0x1f000000;
                                 // clear the priority
   IPC5SET=0x0d000000;
                                  // Set IPL=3, subpriority 1
                                  // Enable Rx, Tx and Error interrupts
   IEC0SET=0x03800000;
   SPI1BRG=0x1;
                                  // use {\rm F}_{\rm PB}/4 clock frequency
                                 // clear the Overflow
   SPI1STATCLR=0x40;
   SPI1CON=0x8220;
                                  // SPI ON, 8 bits transfer, SMP=1, Master Mode
                                  \ensuremath{{//}} from now on, the device is ready to transmit and receive
                                      data
   SPI1BUF='A';
                                  // transmit an A character
```

17.2.3 SLAVE MODE

In Slave mode, data from the SPIxBUF register is transmitted synchronously on the SDO (output) pin while synchronous data is received from the Master device on the SDI (input) pin. In this mode, the Master device controls the synchronous data transfer with the SCK clock pin by generating 8, 16 or 32 clock pulses, depending on the selected data size.

17.2.3.1 Slave Mode Operations

The SDO pin is an output and the SPI pin is an input. Setting the control bit, DISSDO (SPIxCON<12>), disables transmission at the SDO pin if Receive Only mode of operation is desired.

Refer to Table 17-7.

The SDI (input) must be configured to properly sample the data received from the slave device by configuring the sample bit, SMP (SPIxCON<9>).

Refer to timing diagram shown in Figure 17-4 to determine the appropriate settings.

Data transfers can be 8, 16, or 32 bits and are configured using control bits. MODE<32,16> (SPIxCON<11:10>).

Refer to Section 17.2.1 "8, 16, 32-Bit Operation" for details.

Slave Select Synchronization: The SSx pin allows a Synchronous Slave mode. If the SSEN (SPIxCON<7>) bit is set, transmission and reception is enabled in Slave mode only if the SSx pin is driven to a low state. If the SSEN bit is not set, the SSx pin does not affect the module operation in Slave mode.

17.2.3.2 Slave SPIxCON Configuration

The following bits must be configured as shown for the Slave mode of operation when configuring the SPIxCON register:

- Enable Slave Mode MSTEN (SPIxCON<5>) = 0.
- Disable Framed SPI support FRMEN (SPIxCON<31>) = 0

The remaining bits are shown with example configurations and may be configured as desired:

- Enable module control of SDO pin DISSDO (SPIxCON<12>) = 0
- Configure SCK clock polarity to Idle high CKP (SPIxCON<6>) = 1
- Configure SCK clock edge transition from Idle to active – CKE (SPIxCON<8>) = 0
- Disable Slave Select Pin SSEN (SPIxCON<7>) = 0
- Select 16-bit data width MODE<32,16> (SPIxCON<11:10>) = 01
- Sample data input at middle SMP (SPIxCON<9>) = 0

 Enable SPI module when CPU Idle – SIDL (SPIxCON<13>) = 0

17.2.3.3 Slave Mode Initialization

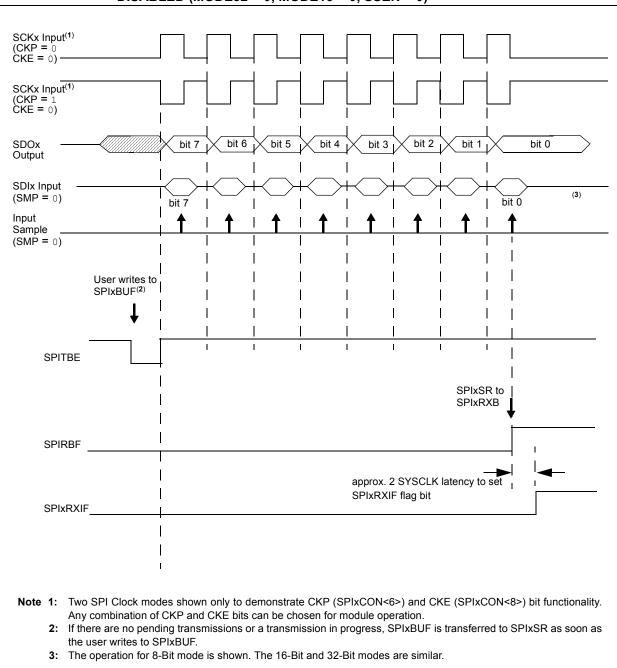

The following steps are used to set up the SPI module for the Slave mode of operation:

- 1. If interrupts are used, disable the SPI interrupts in the respective IEC0/1 register.
- 2. Stop and reset the SPI module by clearing the ON bit.
- 3. Clear the receive buffer.
- 1. If using interrupts, the following additional steps are performed:
 - Clear the SPIx interrupt flags/events in the respective IFS0/1 register.
 - Set the SPIx interrupt enable bits in the respective IEC0/1 register.
 - Write the SPIx interrupt priority and subpriority bits in the respective IPC5/7 register.
- 2. Clear the SPIROV bit (SPIxSTAT<6>).
- Write the selected configuration settings to the SPIxCON register with MSTEN (<SPIxCON<5>) = 0.
- Enable SPI operation by setting the ON bit (SPIxCON<15>).
- 5. Transmission (and reception) will start as soon as the master provides the serial clock.

Note 1: The user must turn off the SPI device prior to changing the CKE or CKP bits. Otherwise, the behavior of the device is not ensured.

- 2: The SPI device must be turned off prior to changing the mode from Master to Slave.
- The SPIxSR register cannot be written into directly by the user. All writes to the SPIxSR register are performed through the SPIxBUF register.

EXAMPLE 17-2: FOR 16-BIT SPI SLAVE MODE INITIALIZATION

```
The following code example will initialize the SPI1 in slave mode with SSEN.
   It assumes that the SPI1 SS input pin on RB2 is shared with the AN2 analog input.
   It thus properly configures the corresponding AD1PCFG and TRIS registers bits.
*/
   int
          rData:
   IEC0CLR=0x03800000;
                                     // disable all interrupts
   SPI1CON = 0;
                                     // Stops and resets the SPI1.
   TRISBSET = 0x4;
                                    // Set RB2 as a digital input
   AD1PCFGSET = 0 \times 4;
                                    // Analog input pin in digital mode
                                    // clears the receive buffer
   rData=SPI1BUF;
   IFS0CLR=0x03800000;
                                     // clear any existing event
                                     // clear the priority
   IPC5CLR=0x1f000000;
                                     // Set IPL=3, subpriority 1
   IPC5SET=0x0d000000;
   IEC0SET=0x03800000;
                                     // Enable Rx, Tx and Error interrupts
   SPI1STATCLR=0x40;
                                     // clear the Overflow
                                     // SPI ON, 8 bits transfer, Slave Mode
   SPI1CON=0x8000;
                                     // from now on, the device is ready to receive and
                                         transmit data
```

17.2.4 FRAMED SPI MODES

The module supports a very basic framed SPI protocol while operating in either Master or Slave modes. The following features are provided in the SPI module to support Framed SPI modes:

- The control bit, FRMEN (SPIxCON<31>), enables Framed SPI mode and causes the SSx pin to be used as a frame synchronization pulse input or output pin. The state of the SSEN (SPIxCON<7>) is ignored.
- The control bit, FRMSYNC (SPIxCON<30>), determines whether the SSx pin is an input or an output (i.e., whether the module receives or generates the frame synchronization pulse).
- The FRMPOL (SPIxCON<29>) determines the frame synchronization pulse polarity for a single SPI clock cycle.

The following framed SPI modes are supported by the SPI module:

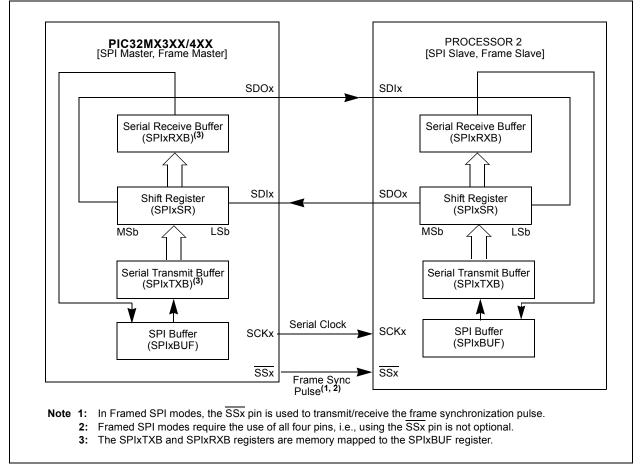

- Frame Master mode: The SPI module generates the frame synchronization pulse and provides this pulse to other devices at the SSx pin.
- Frame Slave mode: The SPI module uses a frame synchronization pulse received at the SSx pin.

The Framed SPI modes are supported in conjunction with the Master and Slave modes. Thus, the following framed SPI configurations are available:

- SPI Master mode and Frame Master mode
- · SPI Master mode and Frame Slave mode
- · SPI Slave mode and Frame Master mode
- · SPI Slave mode and Frame Slave mode

These four modes determine whether or not the SPI module generates the serial clock and the frame synchronization pulse.

© 2008 Microchip Technology Inc.

17.2.4.1 SPI Master Mode and Frame Master Mode Operations

This Framed SPI mode is enabled by setting bits MSTEN (SPIxCON<5>) and FRMEN (SPIxCON<31>) to '1', and bit FRMSYNC (SPIxCON<30>) to '0'. In this mode, the serial clock will be output continuously at the SCKx pin, regardless of whether the module is transmitting. When SPIxBUF is written, the SSx pin will be driven active, high or low depending on bit FRMPOL (SPIxCON<29>), on the next transmit edge of the SCKx clock. The SSx pin will be active for one SCKx clock cycle. The module will start transmitting data on the same or on the next transmit edge of the SCKx, depending on the SPIFE (SPIxCON<17>) setting, as shown in Figure 17-6. A connection diagram indicating signal directions for this operating mode is shown in Figure 17-5.

The SCK, SDO and SSx pins are outputs, the SDI pin is an input. Setting the control bit, DISSDO (SPIxCON<12>), disables transmission at the SDO pin if Receive Only mode of operation is desired.

Refer to Table 17-7.

The SDI (input) must be configured to properly sample the data received from the slave device by configuring the sample bit, SMP (SPIxCON<9>).

In Master mode, the SCK clock edge and polarity must be configured properly for the master and slave device to correctly transfer data synchronously.

Refer to timing diagram shown in Figure 17-3 to determine the appropriate settings.

17.2.4.2 Master SPIxCON Configuration

The following bits must be configured as shown for the Master mode of operation when configuring the SPIxCON register:

- Enable Master Mode MSTEN (SPIxCON<5>) = 1
- Enable Framed SPI support FRMEN (SPIxCON<31>) = 1
- Select SSx pin as Frame Master (output) FRMSYNC(SPIxCON<30>) = 0

The remaining bits are shown with example configurations and may be configured as desired:

- Enable module control of SDO pin SDO (SPIxCON<12>) = 0
- Configure SCK clock polarity to Idle high CKP (SPIxCON<6>) = 1
- Configure SCK clock edge transition from Idle to active – CKE (SPIxCON<8>) = 0
- Select SSx active-low pin polarity FRMPOL (SPIxCON<29>) = 0
- Select 16-bit data width MODE<32,16> (SPIxCON<11:10>) = 01

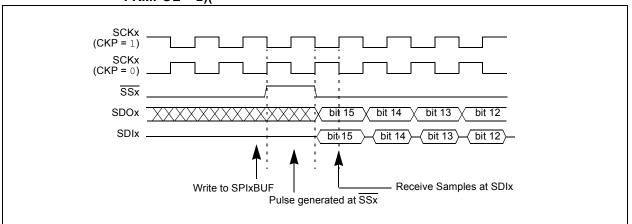

- Sample data input at middle SMP (SPIxCON<9>) = 0
- Enable SPI module when CPU Idle SIDL (SPIxCON<13>) = 0

17.2.4.3 Framed Master Mode Initialization

The following steps are used to set up the SPI module for the Master mode of operation:

- 1. If interrupts are used, disable the SPI interrupts in the respective IEC0/1 register.
- 2. Stop and reset the SPI module by clearing the ON bit.
- 3. Clear the receive buffer.
- 4. If using interrupts, the following additional steps are performed:
 - Clear the SPIx interrupt flags/events in the respective IFS0/1 register.
 - Set the SPIx interrupt enable bits in the respective IEC0/1 register.
 - Write the SPIx interrupt priority and subpriority bits in the respective IPC5/7 register.
- 5. Clear the SPIROV bit (SPIxSTAT<6>).
- 6. Write the selected configuration settings to the SPIxCON register.
- Enable SPI operation by setting the ON bit (SPIxCON<15>).
 - Note 1: The user must turn off the SPI device prior to changing the CKE or CKP bits. Otherwise, the behavior of the device is not ensured.
 - 2: The SPIxSR register cannot be written into directly by the user. All writes to the SPIxSR register are performed through the SPIxBUF register.

FIGURE 17-6: SPI MASTER, FRAME MASTER MODE32 = 0, MODE16 = 1, SPIFE = 0, FRMPOL = 1)(

17.2.4.4 SPI Master Mode and Frame Slave Mode Operations

This Framed SPI mode is enabled by setting bits MSTEN (SPIxCON<5>), FRMEN (SPIxCON<31>), and FRMSYNC (SPIxCON<30>) to '1'. The SSx pin is an input, and it is sampled on the sample edge of the SPI clock. When it is sampled active, high, or low depending on bit FRMPOL (SPIxCON<29>), data will be transmitted on the subsequent transmit edge of the SPI clock, as shown in Figure 17-7. The interrupt flag SPIxIF is set when the transmission is complete. The user must make sure that the correct data is loaded into the SPIxBUF for transmission before the signal is received at the SSx pin. A connection diagram indicating signal directions for this operating mode is shown in Figure 17-8.

The SCK and SDO pins are outputs, the SDI and \overline{SSx} pins are inputs. Setting the control bit, DISSDO (SPIxCON<12>), disables transmission at the SDO pin if Receive Only mode of operation is desired.

Refer to Table 17-7.

The SDI pin must be configured to properly sample the data received from the slave device by configuring the sample bit, SMP (SPIxCON<9>).

In Master mode, the SCK clock edge and polarity must be configured properly for the master and slave device to correctly transfer data synchronously.

Refer to timing diagram shown in Figure 17-3 to determine the appropriate settings.

17.2.4.5 Master SPIxCON Configuration

The following bits must be configured as shown for the Master mode of operation when configuring the SPIxCON register:

- Enable Master Mode MSTEN (SPIxCON<5>) = 1
- Enable Framed SPI support –
 FRMEN (SPIxCON<31>) = 1
- Select SSx pin as Frame Slave (input) FRMSYNC (SPIxCON<30>) = 1

The remaining bits are shown with example configurations and may be configured as desired:

- Enable module control of SDO pin DISSDO (SPIxCON<12>) = 0
- Configure SCK clock polarity to Idle high CKP (SPIxCON<6>) = 1
- Configure SCK clock edge transition from Idle to active – CKE (SPIxCON<8>) = 0
- Select SSx active low pin polarity FRMPOL (SPIxCON<29>) = 0
- Select 16-bit data width MODE<32,16> (SPIxCON<11:10>) = 01
- Sample data input at middle SMP (SPIxCON<9>) = 0

 Enable SPI module when CPU Idle – SIDL (SPIxCON<13>) = 0

17.2.4.6 Framed Slave Mode Initialization

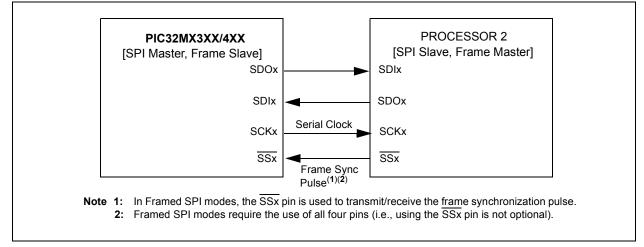

The following steps are used to set up the SPI module for the Slave mode of operation:

- 1. If interrupts are used, disable the SPI interrupts in the respective IEC0/1 register.
- 2. Stop and reset the SPI module by clearing the ON bit.
- 3. Clear the receive buffer.
- 4. If using interrupts, the following additional steps are performed:
 - Clear the SPIx interrupt flags/events in the respective IFS0/1 register.
 - Set the SPIx interrupt enable bits in the respective IEC0/1 register.
 - Write the SPIx interrupt priority and subpriority bits in the respective IPC5/7 register.
- 5. Clear the SPIROV bit (SPIxSTAT<6>).
- 6. Write the selected configuration settings to the SPIxCON register.
- Enable SPI operation by setting the ON bit (SPIxCON<15>).
 - Note 1: The user must turn off the SPI device prior to changing the CKE or CKP bits. Otherwise, the behavior of the device is not ensured.
 - 2: The SPIxSR register cannot be written into directly by the user. All writes to the SPIxSR register are performed through the SPIxBUF register.
 - **3:** Receiving a frame sync pulse will start a transmission, regardless of whether or not data was written to SPIxBUF. If a write was not performed, zeros will be transmitted.

FIGURE 17-7: SPI MASTER, FRAME SLAVE MODE32 = 0, MODE16 = 1, SPIFE = 0, FRMPOL = 1)(

17.2.4.7 SPI Slave Mode and Frame Master Mode

This Framed SPI mode is enabled by setting bit MSTEN (SPIxCON<5>) to '0', bit FRMEN (SPIxCON<31>) to '1' and bit FRMSYNC (SPIxCON<30>) to '0'. The input SPI clock will be continuous in Slave mode. The SSx pin will be an output when bit FRMSYNC is low. Therefore, when SPIBUF is written, the module will drive the SSx pin active, high or low depending on bit FRMPOL (SPIxCON<29>), on the next transmit edge of the SPI clock. The SSx pin will be driven active for one SPI clock cycle. Data transmission will start on the next SPI clock transmit edge. A connection diagram indicating signal directions for this operating mode is shown in Figure 17-9.

The SDO and \overline{SSx} pins are outputs and the SCK and SDI pins are inputs. Setting the control bit, DISSDO (SPIxCON<12>), disables transmission at the SDO pin if Receive Only mode of operation is desired.

Refer to Table 17-7.

The SDI pin must be configured to properly sample the data received from the slave device by configuring the sample bit, SMP (SPIxCON<9>).

Refer to timing diagram shown in Figure 17-6 to determine the appropriate settings.

17.2.4.8 Slave SPIxCON Configuration

The following bits must be configured as shown for the Slave mode of operation when configuring the SPIxCON register:

- Enable Slave Mode MSTEN (SPIxCON<5>) = 1
- Enable Framed SPI support FRMEN (SPIxCON<31>) = 1
- Select SSx pin as Frame Master (output) FRMSYNC(SPIxCON<30>) = 0

The remaining bits are shown with example configurations and may be configured as desired:

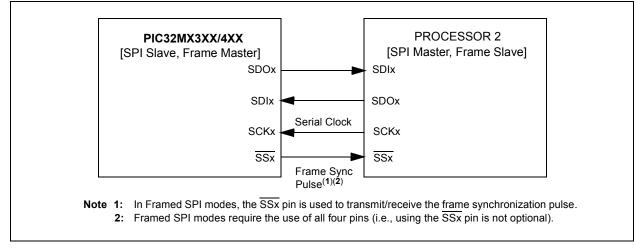

- Enable module control of SDO pin DISSDO (SPIxCON<12>) = 0
- Configure SCK clock polarity to Idle high CKP (SPIxCON<6>) = 1
- Configure SCK clock edge transition from Idle to active – CKE (SPIxCON<8>) = 0
- Select SSx active low pin polarity FRMPOL (SPIxCON<29>) = 0
- Select 16-bit data width MODE<32,16> (SPIxCON<11:10>) = 01
- Sample data input at middle SMP (SPIxCON<9>) = 0
- Enable SPI module when CPU Idle SIDL (SPIxCON<13>) = 0

17.2.4.9 Framed Master Mode Initialization

The following steps are used to set up the SPI module for the Slave mode of operation:

- 1. If interrupts are used, disable the SPI interrupts in the respective IEC0/1 register.
- 2. Stop and reset the SPI module by clearing the ON bit.
- 3. Clear the receive buffer.
- 4. If using interrupts, the following additional steps are performed:
 - Clear the SPIx interrupt flags/events in the respective IFS0/1 register.
 - Set the SPIx interrupt enable bits in the respective IEC0/1 register.
 - Write the SPIx interrupt priority and subpriority bits in the respective IPC5/7 register.
- 5. Clear the SPIROV bit (SPIxSTAT<6>).
- 6. Write the selected configuration settings to the SPIxCON register.
- Enable SPI operation by setting the ON bit (SPIxCON<15>).
- 8. Transmission (and reception) will start as soon as the master provides the serial clock.
 - Note 1: The user must turn off the SPI device prior to changing the CKE or CKP bits. Otherwise, the behavior of the device is not ensured.
 - 2: The SPIxSR register cannot be written into directly by the user. All writes to the SPIxSR register are performed through the SPIxBUF register.

17.2.4.10 SPI Slave Mode and Frame Slave Mode

This Framed SPI mode is enabled by setting bits MSTEN (SPIxCON<5>) to '0', FRMEN (SPIxCON<31>) to '1', FRMSYNC and (SPIxCON<30>) to '1'. Therefore, both the SCKx and SSx pins will be inputs. The SSx pin will be sampled on the sample edge of the SPI clock. When SSx is sampled active, high or low depending on bit, FRMPOL (SPIxCON<29>), data will be transmitted on the next transmit edge of SCKx. A connection diagram indicating signal directions for this operating mode is shown in Figure 17-10.

The SDO pins is an output and the SCK, SDI and \overline{SSx} pins are inputs. Setting the control bit, DISSDO (SPIxCON<12>), disables transmission at the SDO pin if Receive Only mode of operation is desired.

Refer to Table 17-7.

The SDI pin must be configured to properly sample the data received from the slave device by configuring the sample bit, SMP (SPIxCON<9>).

Refer to timing diagram shown in Figure 17-7 to determine the appropriate settings.

17.2.4.11 Slave SPIxCON Configuration

The following bits must be configured as shown for the Slave mode of operation when configuring the SPIxCON register:

- Enable Slave Mode MSTEN (SPIxCON<5>) = 0
- Enable Framed SPI support –
 FRMEN (SPIxCON<31>) = 1
- Select SSx pin as Frame Slave (input) FRMSYNC(SPIxCON<30>) = 1

The remaining bits are shown with example configurations and may be configured as desired:

- Enable module control of SDO pin DISSDO (SPIxCON<12>) = 0
- Configure SCK clock polarity to Idle high CKP (SPIxCON<6>) = 1
- Configure SCK clock edge transition from Idle to active – CKE (SPIxCON<8>) = 0
- Select SSx active-low pin polarity FRMPOL (SPIxCON<29>) = 0
- Select 16-bit data width MODE<32,16> (SPIxCON<11:10>) = '01'
- Sample data input at middle SMP (SPIxCON<9>) = 0
- Enable SPI module when CPU Idle SIDL (SPIxCON<13>) = 0

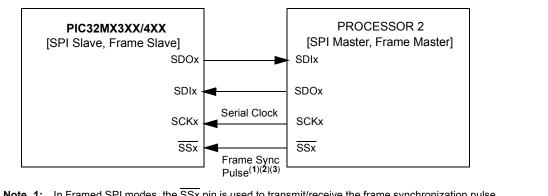

17.2.4.12 Framed Slave Mode Initialization

The following steps are used to set up the SPI module for the Slave mode of operation:

- 1. If interrupts are used, disable the SPI interrupts in the respective IEC0/1 register.
- Stop and reset the SPI module by clearing the 2. ON bit.
- 3. Clear the receive buffer.
- 4. If using interrupts, the following additional steps are performed:
 - · Clear the SPIx interrupt flags/events in the respective IFS0/1 register.
 - · Set the SPIx interrupt enable bits in the respective IEC0/1 register.
 - · Write the SPIx interrupt priority and subpriority bits in the respective IPC5/7 register.
- 5. Clear the SPIROV bit (SPIxSTAT<6>).
- 6. Write the selected configuration settings to the SPIxCON register.

- Enable SPI operation by setting the ON bit 7 (SPIxCON<15>).
- 8. Transmission (and reception) will start as soon as the master provides the serial clock.
 - Note 1: The user must turn off the SPI device prior to changing the CKE or CKP bits. Otherwise, the behavior of the device is not ensured.
 - 2: The SPIxSR register cannot be written into directly by the user. All writes to the SPIxSR register are performed through the SPIxBUF register.
 - 3: Receiving a frame sync pulse will start a transmission, regardless of whether or not data was written to SPIxBUF. If a write was not performed, zeros will be transmitted.

FIGURE 17-10: SPI SLAVE, FRAME SLAVE CONNECTION DIAGRAM

Note 1: In Framed SPI modes, the SSx pin is used to transmit/receive the frame synchronization pulse.

2: Framed SPI modes require the use of all four pins (i.e., using the SSx pin is not optional).

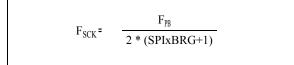

3: Slave Select is not available when using Frame mode as a slave device.

17.2.5 SPI MASTER MODE CLOCK FREQUENCY

In Master mode, the SPI module clock source is the peripheral bus clock (PBCLK) and the SCK clock baud rate is derived from the PBCLK clock and the SPIxBRG register.

Equation 17-1 defines the SCKx clock frequency as a function of the SPIxBRG register settings.

EQUATION 17-1: SPI CLOCK FREQUENCY

Note that the maximum possible baud rate is $F_{PB}/2$ (SPIXBRG = 0) and the minimum possible baud rate is $F_{PB}/1024$.

Sample SPI clock frequencies are shown in the table Table 17-6.

Note: The SCKx signal clock is not free running for nonframed SPI modes. It will only run for 8, 16 or 32 pulses when the SPIxBUF is loaded with data. It will however, be continuous for Framed modes.

SPIxBRG setting	0	15	31	63	85	127
F _{PB} = 50 MHz	25.00 MHz	1.56 MHz	781.25 KHz	390.63 KHz	290.7 KHz	195.31 KHz
F _{PB} = 40 MHz	20.00 MHz	1.25 MHz	625.00 KHz	312.50 KHz	232.56 KHz	156.25 KHz
F _{PB} = 25 MHz	12.50 MHz	781.25 KHz	390.63 KHz	195.31 KHz	145.35 KHz	97.66 KHz
F _{PB} = 20 MHz	10.00 MHz	625.00 KHz	312.50 KHz	156.25 KHz	116.28 KHz	78.13 KHz
F _{PB} = 10 MHZ	5.00 MHz	312.50 KHz	156.25 KHz	78.13 KHz	58.14 KHz	39.06 KHz

TABLE 17-6: SAMPLE SCKX FREQUENCIES

17.2.6 SPI Error Handling

When a new data word has been shifted into shift register SPIxSR and the previous contents of receive register SPIxRXB have not been read by the user software, the SPIROV bit (SPIxSTAT<6>) will be set. The module will not transfer the received data from SPIxSR to the SPIxRXB. Further data reception is disabled until the SPIROV bit is cleared. The SPIROV bit is not cleared automatically by the module and must be cleared by the user software.

17.3 SPI Interrupts

The SPI module has the ability to generate interrupts reflecting the events that occur during the data communication. The following types of interrupts can be generated:

- Receive data available interrupts, signalled by SPI1RXIF (IFS0<25>), SPI2RXIF (IFS1<7>). This event occurs when there is new data assembled in the SPIxBUF receive buffer.
- Transmit buffer empty interrupts, signalled by SPI1TXIF (IFS0<24>), SPI2TXIF (IFS1<6>). This event occurs when there is space available in the SPIxBUF transmit buffer and new data can be written.
- Receive buffer overflow interrupts, signalled by SPI1EIF (IFS0<23>), SPI2EIF(IFS1<5>).
 This event occurs when there is an overflow condition for the SPIxBUF receive buffer, i.e., new receive data assembled but the previous one is not read.

An SPI device is enabled as a source of interrupts via the respective SPI interrupt enable bits:

- SPI1RXIE (IEC0<25>) and SPI2RXIE (IEC1<7>)
- SPI1TXIE (IEC0<24>) and SPI2TXIE (IEC1<6>)
- SPI1EIE (IEC0<23>) and SPI2EIE (IEC1<5>)

The interrupt priority level bits and interrupt subpriority level bits must be also be configured:

- SPI1IP (IPC5<28:26>), SPI1IS (IPC5<25:24>)
- SPI2IP (IPC7<28:26>), SPI2IS (IPC7<25:24>)

In addition to enabling the SPI interrupts, an Interrupt Service Routine, ISR, is required. Example 17-3 is a partial code example of an ISR.

Note: It is the user's responsibility to clear the corresponding interrupt flag bit before returning from an ISR.

EXAMPLE 17-3: SPI INITIALIZATION WITH INTERRUPTS ENABLED

```
The following code example illustrates an SPI1 interrupt configuration.
   When the SPI1 interrupt is generated, the cpu will jump to the vector assigned to SPI1
   interrupt.
   It assumes that none of the SPI1 input pins are shared with an analog input.
   If so, the AD1PCFG and corresponding TRIS registers have to be properly configured.

```

EXAMPLE 17-4: SPI1 ISR

17.4 I/O Pin Control

Enabling the SPI modules will configure the I/O pin direction as defined by the SPI control bits (see Table 17-7). The port TRIS and LATCH registers will be overridden.

TADLE 17-7:	"OT IN	CONFIGURATIO			_

TABLE 17-7: I/O PIN CONFIGURATION FOR USE WITH SPI MODULES

Legend: CMOS = CMOS compatible input or output; ST = Schmitt Trigger input with CMOS levels; I = Input; O = Output; X = Don't Care

- 2: The Slave Select pins are only required when a select signal to the slave device is needed. Otherwise, these pins can be used for general purpose I/O and require the user to set the corresponding TRIS control register bits.
- 3: These bits are contained in the SPIxCON register.
- **4:** The setting of the TRIS bit is irrelevant.
- **5:** If the input pin is shared with an analog input, then the AD1PCFG and the corresponding TRIS register have to be properly set to configure this input as digital.

Note 1: The SDO pins are only required when SPI data output is needed. Otherwise, these pins can be used for general purpose I/O and require the user to set the corresponding TRIS control register bits.

18.0 INTER-INTEGRATED CIRCUIT (I²C™)

Note:	This data sheet summarizes the features of
	the PIC32MX3XX/4XX family of devices. It
	is not intended to be a comprehensive refer-
	ence source. Refer to the "PIC32MX Family
	Reference Manual" (DS61132) for a
	detailed description of this peripheral.

The Inter-Integrated Circuit (I^2C) module provides complete hardware support for both Slave and Multi-Master modes of the I^2C serial communication standard. Figure 18-1 shows the I^2C module block diagram.

The PIC32MX3XX/4XX devices have up to two I^2C interface modules, denoted as I2C1 and I2C2. Each I^2C module has a 2-pin interface: the SCLx pin is clock and the SDAx pin is data.

Each I^2C module 'I2Cx' (x = 1 or 2) offers the following key features:

- I²C Interface Supporting both Master and Slave Operation.
- I²C Slave Mode Supports 7 and 10-Bit Address.
- I²C Master Mode Supports 7 and 10-Bit Address.
- I²C Port allows Bidirectional Transfers between Master and Slaves.
- Serial Clock Synchronization for I²C Port can be used as a Handshake Mechanism to Suspend and Resume Serial Transfer (SCLREL control).
- I²C Supports Multi-master Operation; Detects Bus Collision and Arbitrates Accordingly.
- Provides Support for Address Bit Masking.

18.1 Operating Modes

The hardware fully implements all the master and slave functions of the I^2C Standard and Fast mode specifications, as well as 7 and 10-bit addressing.

The I^2C module can operate either as a slave or a master on an I^2C bus.

The following types of I^2C operation are supported:

- I²C Slave Operation with 7 or 10-Bit Address
- I²C Master Operation with 7 or 10-Bit Address

For details about the communication sequence in each of these modes, please refer to the "*PIC32MX3XX/4XX Reference Manual*" (DS61132).

18.2 I²C Registers

The I2CxCON register allows control of the module's operation. The I2CxCON register is readable and writable. I2CxSTAT register contains status flags indicating the module's state during operation.

I2CxRCV is the receive register. When the incoming data is shifted completely, it is moved to the I2CxRCV register. I2CxTRN is the transmit register to which bytes are written during a transmit operation.

The I2CxADD register holds the slave address. A Status bit, ADD10, indicates 10-Bit Addressing mode. The I2CxBRG acts as the Baud Rate Generator (BRG) reload value.

In receive operations, I2CxRSR and I2CxRCV together form a double-buffered receiver. When I2CxRSR receives a complete byte, it is transferred to I2CxRCV and an interrupt pulse is generated. The I2CxRSR shift register is not directly accessable to the programmer.

18.3 I²C Interrupts

The I²C module generates three interrupt signals: Slave Interrupt (I2CxSIF), Master Interrupt (I2CxMIF) and Bus Collision Interrupt (I2CxBIF).

18.4 Baud Rate Generator

In I²C Master mode, the reload value for the Baud Rate Generator (BRG) resides in the I2CxBRG register. When the BRG is loaded with this value, the BRG counts down to '0' and stops until another reload has taken place. If clock arbitration is taking place, for instance, the BRG is reloaded when the SCLx pin is sampled high.

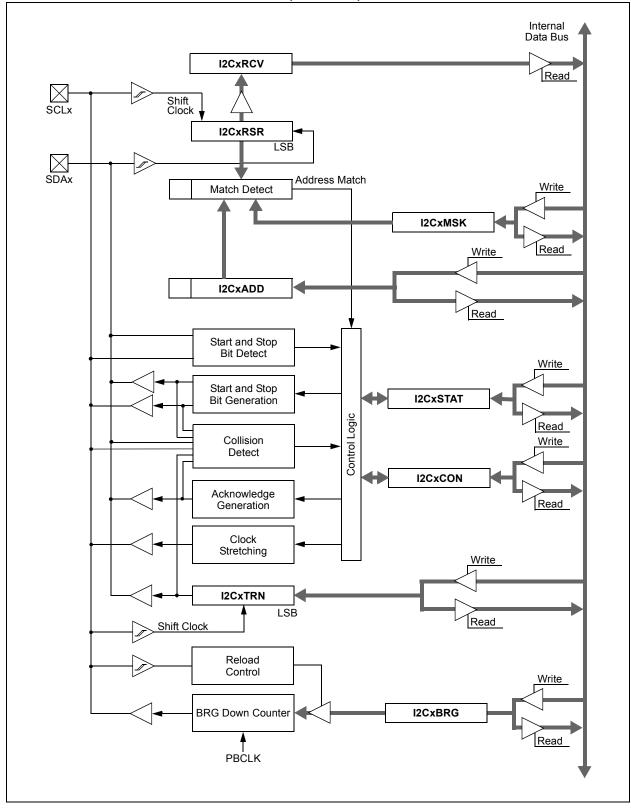

As per the I²C standard, FSCL may be 100 kHz or 400 kHz. However, the user can specify any baud rate up to 1 MHz. I2CxBRG values of '0' or '1' are illegal.

EQUATION 18-1: SERIAL CLOCK RATE

PBCLK is the peripheral clock speed. FSCL is the desired $\mathsf{I}^2\mathsf{C}$ bus speed.

FIGURE 18-1: I^2C^{TM} BLOCK DIAGRAM (x = 1 OR 2)

18.5 I²C Module Addresses

The I2CxADD register contains the Slave mode addresses. The register is a 10-bit register.

If the A10M bit (I2CxCON<10>) is '0', the address is interpreted by the module as a 7-bit address. When an address is received, it is compared to the 7 Least Significant bits of the I2CxADD register.

If the A10M bit is '1', the address is assumed to be a 10-bit address. When the first address byte is received, it will be compared with the binary value, '11110 A9 A8 R/W = 0 (where A9 and A8 are Most Significant bits of the 10-bit address stored in I2CxADD). If that value matches, the next address byte will be compared with the Least Significant 8 bits of I2CxADD, as specified in the 10-bit addressing protocol.

TABLE 18-1: 7-BIT I²C™ SLAVE ADDRESSES SUPPORTED BY PIC32MX3XX/4XX

0x00	General call address or Start byte
0x01-0x03	Reserved
0x04-0x07	Hs mode Master codes
0x08-0x77	Valid 7-bit addresses
0x78-0x7b	10-bit address upper byte
0x7c-0x7f	Reserved

18.6 Slave Address Masking

The I2CxMSK register (Register 18-4) designates address bit positions as "don't care" (= 1) for both 7-bit and 10-Bit Addressing modes. Setting a particular bit location (= 1) in the I2CxMSK register, causes the slave module to respond, whether the corresponding address bit value is a '0' or '1'. For example, when I2CxMSK is set to '00110000', the slave module will detect both addresses, '0000000' and '00100000'.

18.7 Strict Addressing Support

The control bit, STRICT, enables the module to support the strict addressing. It enables the module to enforce all reserved addresses if they fall within the reserved address table. If the user wants to enforce the reserved address space, the STRICT (I2CxCON<11>) bit must be set to '1'. Once the bit is set, the device will not acknowledge reserved addresses, regardless of the address mask settings.

18.8 General Call Address Support

The general call address is used to address all devices. When this address is used, all devices should, in theory, respond with an Acknowledgement.

The general call address is one of eight addresses reserved for specific purposes by the I^2C protocol. It consists of all '0's with R/W = 0.

The general call address is recognized when the General Call Enable (GCEN) bit is set (I2CxCON<7> = 1). When the interrupt is serviced, the source for the interrupt can be checked by reading the contents of the I2CxRCV to determine if the address was device-specific or a general call address. Upon detection of general call address, GCSTAT (I2CxSTAT<9>) bit is set. This method is available in both 7-Bit and 10-Bit Addressing modes.

18.9 Automatic Clock Stretch

In Slave modes, the module can synchronize buffer reads and writes to the master device by clock stretching.

18.9.1 TRANSMIT CLOCK STRETCHING

Both 10-Bit and 7-Bit Transmit modes implement clock stretching by asserting the SCLREL bit after the falling edge of the ninth clock, if the TBF bit is cleared, indicating the buffer is empty.

In Slave Transmit modes, clock stretching is always performed, irrespective of the STREN bit. The user's ISR must set the SCLREL bit before transmission is allowed to continue. By holding the SCLx line low, the user has time to service the ISR and load the contents of the I2CxTRN before the master device can initiate another transmit sequence.

18.9.2 RECEIVE CLOCK STRETCHING

The STREN bit in the I2CxCON register can be used to enable clock stretching in Slave Receive mode. When the STREN bit is set, the SCLx pin will be held low at the end of each data receive sequence.

The user's ISR must set the SCLREL bit before reception is allowed to continue. By holding the SCLx line low, the user has time to service the ISR and read the contents of the I2CxRCV before the master device can initiate another receive sequence. This will prevent buffer overruns from occurring.

18.10 Software Controlled Clock Stretching (STREN = 1)

When the STREN bit is '1', the SCLREL bit may be cleared by software to allow software to control the clock stretching.

If the STREN bit is '0', a software write to the SCLREL bit will be disregarded and have no effect on the SCLREL bit.

18.11 Slope Control

The I^2C standard requires slope control on the SDAx and SCLx signals for Fast mode (400 kHz). The control bit, DISSLW, enables the user to disable slew rate control if desired. It is necessary to disable the slew rate control for 1 MHz mode.

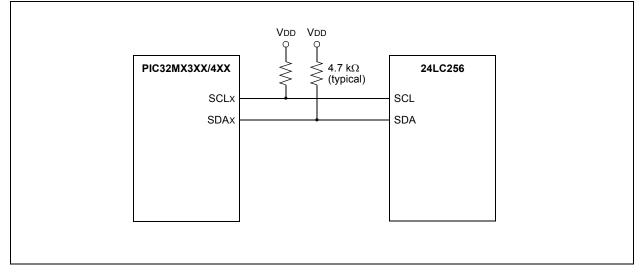

18.12 Clock Arbitration

Clock arbitration occurs when the master deasserts the SCLx pin (SCLx allowed to go high by external pull-up resistors) during any receive, transmit or Restart/Stop condition. When the SCLx pin is allowed to float high, the Baud Rate Generator (BRG) is suspended from counting until the SCLx pin is actually sampled high. When the SCLx pin is sampled high, the Baud Rate Generator is reloaded with the contents of I2CxBRG and begins counting. This ensures that the SCLx high time will always be at least one BRG rollover count in the event that the clock is held low by an external device.

18.13 Multi-Master Communication, Bus Collision and Bus Arbitration

Multi-Master mode support is achieved by bus arbitration. When the master outputs address/data bits onto the SDAx pin, arbitration takes place when the master outputs a '1' on SDAx by letting SDAx float high while another master asserts a '0'. When the SCLx pin floats high, data should be stable. If the expected data on SDAx is a '1' and the data sampled on the SDAx pin = 0, then a bus collision has taken place. The master will set the I^2C master events interrupt flag and reset the master portion of the I^2C port to its Idle state.

NOTES:

19.0 UNIVERSAL ASYNCHRONOUS RECEIVER TRANSMITTER (UART)

Note:	This data sheet summarizes the features of
	the PIC32MX3XX/4XX family of devices. It
	is not intended to be a comprehensive refer-
	ence source. Refer to the "PIC32MX Family
	Reference Manual" (DS61132) for a
	detailed description of this peripheral.

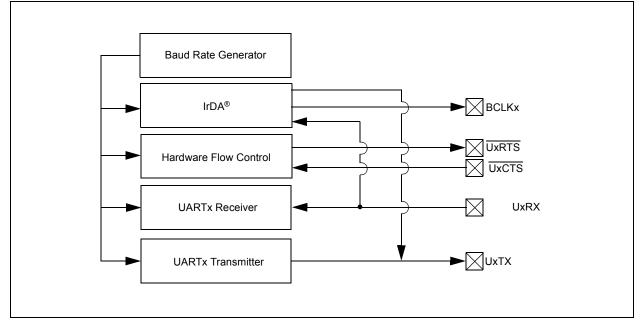

The Universal Asynchronous Receiver Transmitter (UART) module is one of the serial I/O modules available in PIC32MX3XX/4XX family devices. The UART is a full-duplex, asynchronous communication channel that communicates with peripheral devices and personal computers through protocols such as RS-232, RS-485, LIN 1.2 and IrDA[®]. The module also supports the hardware flow control option, with UxCTS and UxRTS pins, and also includes the IrDA encoder and decoder.

The primary features of the UART module are:

- Full-duplex, 8-bit or 9-bit data transmission
- Even, odd or no parity options (for 8-bit data)
- One or two Stop bits
- · Hardware auto-baud feature
- · Hardware flow control option
- Fully integrated Baud Rate Generator (BRG) with 16-bit prescaler
- Baud rates ranging from 47.7 bps to 3.125 Mbps at 50 MHz
- 4-level-deep First-In-First-Out (FIFO) Transmit Data Buffer
- 4-level-deep FIFO Receive Data Buffer
- · Parity, framing and buffer overrun error detection
- Support for interrupt only on address detect (9th bit = 1)
- · Separate transmit and receive interrupts
- Loopback mode for diagnostic support
- · LIN 1.2 protocol support
- IrDA encoder and decoder with 16x baud clock output for external IrDA encoder/decoder support

Figure 19-1 shows a simplified block diagram of the UART.

19.2 **UART Baud Rate Generator (BRG)**

The UART module includes a dedicated 16-bit Baud Rate Generator. The BRGx register controls the period of a free-running 16-bit timer. Equation 19-1 shows the formula for computation of the baud rate with **BRGH =** 0.

EQUATION 19-1: UART BAUD RATE WITH **BRGH** = $0^{(1)}$

$$Baud Rate = \frac{F_{PB}}{16 \cdot (UxBRG + 1)}$$
$$UxBRG = \frac{F_{PB}}{16 \cdot Baud Rate} - 1$$

Note 1: FPB denotes the peripheral bus clock frequency.

Example 19-1 shows the calculation of the baud rate error for the following conditions:

- FPB = 4 MHz
- Desired Baud Rate = 9600

The maximum possible baud rate with BRGH = 0 is Fpb/16.

The minimum possible baud rate is FPB/(16 * 65536).

Equation 19-2 shows the formula for computation of the baud rate with BRGH = 1.

EQUATION 19-2: **UART BAUD RATE WITH** BRGH = $1^{(1)}$

$$Baud Rate = \frac{FPB}{4 \cdot (UxBRG + 1)}$$
$$UxBRG = \frac{FPB}{4 \cdot PB} - 1$$

Note 1: FPB denotes the instruction cycle clock frequency.

4 • Baud Rate

The maximum possible baud rate with BRGH = 1 is FPB/4 for UxBRG = 0, and the minimum possible baud rate is FPB/(4 * 65536).

Writing a new value to the UxBRG register causes the baud rate counter to be cleared. This ensures that the BRG does not wait for a timer overflow before it generates the new baud rate.

EXAMPLE 19-1: **BAUD RATE ERROR CALCULATION (BRGH = 0)**

```
Desired Baud Rate
                     =
                         Fpb/(16 (UxBRG + 1))
Solving for UxBRG value:
   UxBRG
                         ( (Fpb/Desired Baud Rate)/16) - 1
                    =
   UxBRG
                     = ((4000000/9600)/16) - 1
   UxBRG
                    = [25.042] = 25
Calculated Baud Rate = 4000000/(16 (25 + 1))
                    = 9615
                        (Calculated Baud Rate - Desired Baud Rate)
Error
          Desired Baud Rate
                    =
                        (9615 - 9600)/9600
                     = 0.16%
```

19.3 Transmitting in 8-Bit Data Mode

- 1. Set up the UART:
 - a) Write appropriate values for data, parity and Stop bits.
 - b) Write appropriate baud rate value to the UxBRG register.
 - c) Set up transmit and receive interrupt enable and priority bits.
- 2. Enable the UART.
- 3. Set the UTXEN bit (causes a transmit interrupt).
- 4. Write data byte to UxTXREG word. The value will be immediately transferred to the Transmit Shift Register (TSR), and the serial bit stream will start shifting out with next rising edge of the baud clock.
- Alternately, the data byte may be transferred while UTXEN = 0, and then the user may set UTXEN. This will cause the serial bit stream to begin immediately because the baud clock will start from a cleared state.
- 6. A transmit interrupt will be generated as per interrupt control bit, UTXISEL<1:0>.

EXAMPLE 19-2: EXAMPLE 8-BIT DATA MODE

```
/* The following code example demonstrates configuring
    UART1 for 8-bit Data Transmit mode.
*/
U1ERG = #BaudRate;// Set Uart baud rate.
U1MODESET= 0x8000;// Enable Uart for 8-bit Data, no Parity, and 1 Stop bit
U1STASET= 0x1400;// Enable Transmitter and Receiver
```

19.4 Transmitting in 9-Bit Data Mode

- 1. Set up the UART (as described in Section 19.3).
- 2. Enable the UART.
- 3. Set the UTXEN bit (causes a transmit interrupt).
- 4. Write UxTXREG as a 16-bit value only.
- 5. A write to UxTXREG triggers the transfer of the 9-bit data to the TSR. Serial bit stream will start shifting out with the first rising edge of the baud clock.
- A transmit interrupt will be generated as per the setting of control bit, UTXISEL<1:0>.

EXAMPLE 19-3: EXAMPLE 9-BIT DATA MODE

```
/* The following code example demonstrates configuring
    UART1 for 9-bit Data Transmit mode.
*/
U1BRG = #BaudRate;// Set Uart baud rate.
U1MODESET= 0x8006;// Enable Uart for 8-bit Data, no Parity, and 1 Stop bit
U1STASET= 0x1211420;// Enable Address Detect, Set Address = 0x21, Enable Transmitter and
Receiver
```

19.5 Auto-Baud Support

The UART will begin an automatic baud rate measurement sequence whenever a Start bit is received when the Auto-Baud Rate Detect is enabled (ABAUD = 1). This feature is active only while the auto-wake-up is disabled (WAKE = 0). In addition, LPBACK must equal '0' for the auto-baud operation. Following the Start bit, the auto-baud expects to receive an ASCII 'U' (0x55) in order to calculate the proper bit rate. On the 5th UxRX pin rising edge, an accumulated BRG counter value totaling the proper BRG period is transferred to the UxBRG register. The ABAUD bit is automatically cleared.

19.6 Break and Sync Transmit Sequence

The following sequence is performed to send a message frame header that is composed of a Break character, followed by an auto-baud Sync byte. This sequence is typical of a LIN bus master:

- 1. Configure the UART for the desired mode.
- 2. Set UTXEN and UTXBRK to set up the Break character.
- 3. Load the UxTXREG with a dummy character to initiate transmission (value is ignored).
- 4. Write '0x55' to UxTXREG to load the Sync character into the transmit FIFO.

After the Break has been sent, the UTXBRK bit is reset by hardware. The Sync character now transmits.

19.7 Receiving in 8-Bit or 9-Bit Data Mode

- 1. Set up the UART (as described in Section 19.3).
- 2. Enable the UART.
- 3. A receive interrupt will be generated when one or more data characters have been received as per interrupt control bit, URXISEL<1:0>.
- 4. Read the OERR bit to determine if an overrun error has occurred. The OERR bit must be reset in software.
- 5. Read UxRXREG.

The act of reading the UxRXREG character will move the next character to the top of the receive FIFO, including a new set of PERR and FERR values.

19.8 Operation of UxCTS and UxRTS Control Pins

UARTx Clear to Send (UxCTS) and Request to Send (UxRTS) are the two hardware controlled pins that are associated with the UART module. These two pins allow the UART to operate in Simplex and Flow Control mode. They are implemented to control the transmission and reception between the Data Terminal Equipment (DTE). The UEN<1:0> bits in the UxMODE register configure these pins.

19.9 Infrared Support

The UART module provides two types of infrared UART support:

- IrDA clock output to support external IrDA encoder and decoder device (legacy module support)
- Full implementation of the IrDA encoder and decoder

19.10 External IrDA Support – IrDA Clock Output

To support external IrDA encoder and decoder devices, the BCLKx pin (same as the UxRTS pin) can be configured to generate the 16x baud clock. With UEN<1:0> = 11, the BCLKx pin will output the 16x baud clock (if the UART module is enabled). It can be used to support the IrDA codec chip.

19.11 Built-in IrDA Encoder and Decoder

The UART has full implementation of the IrDA encoder and decoder as part of the UART module. The built-in IrDA encoder and decoder functionality is enabled using the IREN bit (UxMODE<12>). When enabled (IREN = 1), the receive pin (UxRX) acts as the input from the infrared receiver. The transmit pin (UxTX) acts as the output to the infrared transmitter.

19.12 UART Interrupts

The UART device has the ability to generate interrupts, reflecting the events that occur during data communication. The following types of interrupts can be generated:

- Receiver-data-available interrupts, signalled by U1RXIF (IFS0<27>), U2RXIF (IFS1<9>). This event occurs when there is new data assembled in the UxRXBUF receive buffer.
- Transmitter-buffer-empty interrupts, signalled by U1TXIF (IFS0<28>), U2TXIF (IFS1<10>). This event occurs when there is space available in the UxTXBUF transmit buffer and new data can be written.
- Receiver-buffer-overflow interrupt, signalled by U1EIF (IFS0<26>), U2EIF (IFS1<8>). This event occurs when there is an overflow condition for the UxRXBUF receive buffer, i.e., new receive data assembled but the previous one not read.

A UART device is enabled as a source of interrupts via the respective UART interrupt enable bits:

- U1RXIE (IEC0<27>) and U2RXIE (IEC1<9>)
- U1TXIE (IEC0<28>) and U2TXIE (IEC1<10>)
- U1EIE (IEC0<26>) and U2EIE (IEC1<8>)

The interrupt priority level bits and interrupt subpriority level bits must be also be configured:

- U1IP (IPC6<4:2>), U1IS (IPC6<1:0>)
- U2IP (IPC8<4:2>), U2IS (IPC8<1:0>).

In addition to enabling the UART interrupts, an Interrupt Service Routine (ISR) is required. Below is a partial code example of an ISR.

Note: It is the user's responsibility to clear the corresponding interrupt flag bit before returning from an ISR.

EXAMPLE 19-4: UART INITIALIZATION WITH INTERRUPTS ENABLE

```
/*
   The following code example illustrates a UART1 interrupt configuration.
   When the UART1 interrupt is generated, the cpu will jump to the vector assigned to UART1
   interrupt.
* /
   IECOCLR=0x1c000000;
                                    // disable all UART1 interrupts
   IFSOCLR=0x1c000000;
                                    // clear any existing event
   IPC6CLR=0x0000001f;
                                    // clear the priority
   TPC6SET=0x000d:
                                    // Set IPL=3, subpriority 1
   IECOSET=0x1c000000;
                                    // Enable Rx, Tx and Error interrupts
                                    // Set Uart baud rate.
   U1BRG = #BaudRate;
   U1MODESET= 0x8000;
                                    // Enable Uart for 8-bit Data, no Parity, and 1 Stop bit
   U1STASET= 0x1400;
                                    // Enable Transmitter and Receiver
```

EXAMPLE 19-5: UART1 ISR

```
/*
   The following code example demonstrates a simple interrupt service routine for UART1
   interrupts. The user's code at this vector should perform any application specific operation
   and must clear the UART1 interrupt flags before exiting.
*/
#pragma interupt Uart1IntHandler ip14 vector 25
void Uart1IntHandler (void)
{
    ... perform application specific operations in response to the interrupt
IFSOCLR = 0x1c000000; // Be sure to clear the UART1 interrupt flags
    // before exiting the service routine.
}
```

19.13 I/O Pin Control

The UART module shares pins with port input/output control and, in some cases, with other modules. To configure a pin for use by the UART, any modules sharing the pin must be disabled. After configuring the UART, the corresponding I/O pins must be configured using the TRIS bit to be an input or output as is required by the UART.

Pin Name	Module Control ⁽²⁾	Controlling Bit Field	Required TRIS bit Setting	Pin Type ⁽¹⁾	Description
U1TX	ON	UTXEN ⁽³⁾ , UEN ⁽²⁾	Output	D, O	UART1 Transmit pin
U2RX	ON	URXEN ⁽³⁾ , UEN ⁽²⁾	Input	D, I	UART1 Receive pin
U1CTS	ON	UEN ⁽²⁾	Input	D, I	UART1 Clear to Send (CTS) Duplex mode
U1RTS	ON	RTSMD ⁽²⁾ , UEN ⁽²⁾	Output	D, O	UART1 Ready to Send (RTS) Duplex mode

Legend:

ST = Schmitt Trigger	input with CMOS levels	I = Input	
O = Output	A = Analog	D = Digital	

Note 1: All pins are subject to the Device Pin Priority Control.

2: Bits are contained in the UxMODE register.

3: Bits are contained in the UxSTA register

20.0 PARALLEL MASTER PORT

Note:	This data sheet summarizes the features of								
	the PIC32MX3XX/4XX family of devices. It								
	is not intended to be a comprehensive refer-								
	ence source. Refer to the "PIC32MX Family								
	Reference Manual" (DS61132) for a								
	detailed description of this peripheral.								

The Parallel Master Port (PMP) is a parallel 8-bit/16-bit input/output module specifically designed to communicate with a wide variety of parallel devices, such as communications peripherals, LCDs, external memory devices, and microcontrollers. Because the interface to parallel peripherals varies significantly, the PMP module is highly configurable.

Key features of the PMP module include:

- 8-bit,16-bit interface
- Up to 16 programmable address lines
- Up to two Chip Select lines
- · Programmable strobe options
 - Individual read and write strobes, or
- Read/write strobe with enable strobe

- · Address auto-increment/auto-decrement
- Programmable address/data multiplexing
- Programmable polarity on control signals
- · Parallel Slave Port support
 - Legacy addressable
 - Address support
 - 4-byte deep auto-incrementing buffer
- · Programmable Wait states
- · Operate during CPU Sleep and Idle modes
- Fast bit manipulation using CLR, SET and INV registers
- Freeze option for in-circuit debugging

Note: On 64-pin devices, data pins PMD<15:8> are not available.

20.2 Modes Of Operation

20.2.1 CONSIDERATIONS FOR PMP MODULE

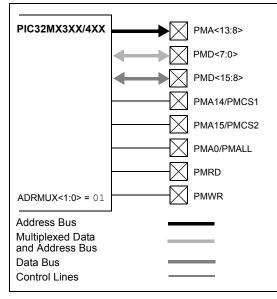

- The PMP module is enabled and ready when the ON bit (PMCON<15>) is set = 1, therefore it is recommended to configure the desired operating mode prior to enabling the module.
- The PMP module is disabled and powered off when the ON bit (PMPCON<15>) = 0, thus providing maximum power savings.
- It is recommended to wait for any pending read or write operation to be completed before enabling/disabling or re-configuring the module

20.2.2 CONSIDERATIONS FOR MASTER MODES

- Setting address bits A15 and A14 = 1 when PMCS2 and PMCS1 are enabled as Chip Selects will cause both PMCS2 and PMCS1 to be active during a read or write operation. This may enable two devices simultaneously and should be avoided.
- It is always recommended to poll the PMP's BUSY bit prior to any read or write operation to ensure the prior PMP operation has completed.

The PMP module offers two Master modes of operation featuring 16-bit or 8-bit data (default), up to 16 bits of address, and all control signals to operate a variety of external parallel devices such as memory devices, peripherals, and slave microcontrollers. An example using Master Mode 2 is shown in Figure 20-2.

FIGURE 20-2: EXAMPLE PMP MASTER MODE 2, PARTIAL MULTIPLEXED INTERFACE

20.2.3 MASTER MODE SELECTION

The two Master modes are selected using MODE<1:0> bits (PMCON<9:8>). Master Mode 1 is selected by configuring MODE<1:0> bits = 11; Master Mode 2 is selected by configuring MODE<1:0> bits = 10.

20.2.4 8, 16-BIT DATA MODES

The PMP in Master mode supports data widths 8 and 16 bits wide. By default, the data width is 8-bit, MODE16 (PMMODE<10>) bit = 0. To select 16-bit data width, set MODE16 = 1. When configured in 8-Bit Data mode, the upper 8 bits of the data bus, PMD<15:8>, are not controlled by the PMP module and are available as general purpose I/O pins.

Note: On 64-pin devices, data pins PMD<15:8> are not available.

20.2.5 CHIP SELECTS

Two Chip Select lines, PMCS1 and PMCS2, are available for the Master modes. The two Chip Select lines are multiplexed with the Most Significant bits of the address bus A14 and A15. If a pin is configured as a Chip Select, it is not included in any PMA<15:0> address auto-increment/decrement. It is possible to enable both PMCS2 and PMCS1 as Chip Selects, or enable only PMCS2 as a Chip Select, allowing PMCS1 to function strictly as address line A14. It is not possible to enable only PMCS1. The Chip Select signals are configured using the Chip Select Function bits CSF<1:0> (PMCON <7:6>).

TABLE 20-3: CHIP SELECT CONTROI

CSF<1:0>	FUNCTION
00	PMCS2 = A15, PMCS1 = A14
01	PMCS2 = Enabled, PMCS1 = A14
10	PMCS2, PMCS1 = Enabled

Refer to **Section 20.2.16** "Addressing Considerations" for information regarding Chip Select address mapping.

20.2.6 PORT PIN CONTROL

The PMAEN register controls the functionality of the address pins PMA<15:0>. Setting any PMAEN bit = 1 configures the corresponding PMA pin as an address line. Those bits set = 0 remain as general purpose I/O pins.

Refer to **Section 20.5 "I/O Pin Control"** regarding I/O pin configuration.

20.2.7 READ/WRITE CONTROL

The PMP module supports two distinct read/write signaling methods. In Master Mode 1, Read and Write strobe are combined into a single control line, PMRD/PMWR; a second control line, PMENB, determines when a read or write action is to be taken.

In Master Mode 2, Read and Write strobes (PMRD and PMWR) are supplied on separate pins.

To enable the PMRD/PMWR and PMWR/PMENB pins, set PTRDEN bit (PMCON<8>) and PTWREN bit (PMCON<9>) = 1.

20.2.8 CONTROL LINE POLARITY

All control signals (PMRD, PMWR, PMALL, PMALH, PMCS2 and PMCS1) can be individually configured for either positive (active-high) or negative (active-low) polarity. The polarity for each control line is controlled by separate bits in the PMCON register.

TABLE 20-4:	MASTER MODE PIN
	POLARITY

CONTROL PIN	PMCON Control Bit	Active-High Select	Active-Low Select
PMRD	RDSP	1	0
PMWR	WRSP	1	0
PMCS2	CS2P	1	0
PMCS1	CS1P	1	0
PMALL/H	ALP	1	0

Note that the polarity of control signals that share the same output pin (for example, PMWR and PMENB) are controlled by the same bit; the configuration depends on which Master Port mode is being used.

20.2.9 AUTO-INCREMENT/DECREMENT

While the module is operating in a Master mode, the auto-address increment/decrement bits INCM<1:0> (PMMODE<12:11>) control the behavior of the address value that appears on the PMA<15:0> address pins. The address in the PMADDR register can be made to automatically increment or decrement by 1 (regardless of the transfer data width) after each read and write operation is completed, and the BUSY bit goes to '0'.

TABLE 20-5:ADDRESS AUTO-
INCREMENT/DECREMENT
CONFIGURATION

INCM<1:0>	FUNCTION
00	No Increment, No Decrement
01	Increment every R/W Cycle
10	Decrement every R/W Cycle

If the Chip Select signals are disabled and configured as address bits, the bits will participate in the increment and decrement operations; otherwise, the PMCS2 and PMCS1 bit values will be unaffected.

20.2.10 WAIT STATES

In Master modes, the user has control over the duration of the read, write, and address cycles by configuring the module Wait states. Three portions of the cycle, the beginning, middle, and end are configured using the corresponding WAITB, WAITM, and WAITE bits in the PMMODE register.

20.2.11 ADDRESS MULTIPLEXING

In either of the Master modes the address bus can be multiplexed together with the data bus. There are three Address Multiplexing modes available; Demultiplexed, Partial Multiplexed and Full Multiplexed. The Addressing Multiplex mode is configured using bits ADRMUX<1:0> (PMCON<12:11).

For detailed examples illustrating address multiplexing configurations, refer to the PMP chapter in the *"PIC32MX Family Reference Manual"* (DS61132).

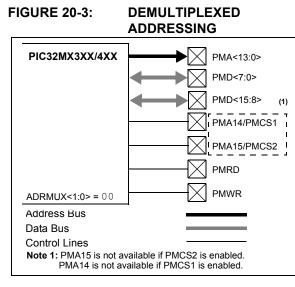

TABLE 20-6:	ADDRESS MULTIPLEX
	CONFIGURATIONS

ADRMUX<1:0>	Multiplex Modes
00	Demultiplexed
01	Partial (uses PMD<7:0>)
10	Full (uses PMD<7:0>)
11	Full (uses PMD<15:0>)

Note: A design implementing partial or full multiplexed address and data bus allows the unused PMA address pins to be used as general purpose I/O pins. However, depending on the Multiplexing mode, read and write operations will be extended by several peripheral bus clock cycles, TPBCLK.

20.2.12 DEMULTIPLEXED MODE

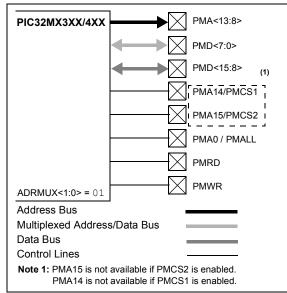

In Demultiplexed mode, address bits are presented on pins PMA<15:0>. Note, PMA15 is not available if PMCS2 is enabled and PMA14 is not available if PMCS1 is enabled. Data bits are presented on pins PMD<15:0> in 16-Bit Data mode; pins PMD<7:0> in 8-Bit Data mode. Demultiplexed mode is selected by configuring bits ADRMUX<1:0> = 00.

20.2.13 PARTIAL MULTIPLEXED MODE

In Partial Multiplexed mode, the lower eight address bits are multiplexed with data pins PMD<7:0>. The upper eight address bits are unaffected and are presented on PMA<15:8>. Note, PMA15 is not available if PMCS2 is enabled and PMA14 is not available if PMCS1 is enabled. The PMA<0> pin is used as an Address Latch, and presents the Address Latch Low enable strobe (PMALL). PMA<7:1> are available as general purpose I/O pins. Partial Multiplexed mode is selected by configuring bits ADRMUX<1:0> = 00.

FIGURE 20-4: PARTIAL MULTIPLEXED ADDRESSING

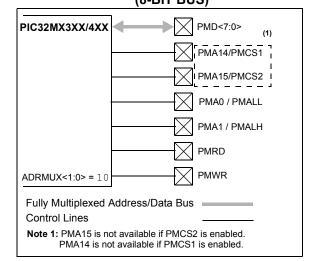

20.2.14 FULL MULTIPLEXED MODE (8-BIT DATA PINS)

In 8-Bit Full Multiplexed mode, the entire 16 bits of the address are multiplexed with the data pins on PMD<7:0>. The PMA<0> and PMA<1> pins are used to present Address Latch Low enable (PMALL) and Address Latch High enable PMALH strobes, respectively. Pins PMA<13:2> are not used as address pins and can be used as general purpose I/O pins. In the event address bits PMA15 or PMA14 are configured as Chip Selects, the corresponding address bits PMADDR<15> and PMADDR<14> are automatically forced = 0. Full 8-Bit Multiplexed mode is selected by configuring bits ADRMUX<1:0> (PMCON<12:11>) = 10.

FIGURE 20-5:

FULL MULTIPLEXED ADDRESSING (8-BIT BUS)

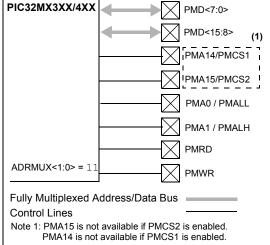

20.2.15 FULL MULTIPLEXED MODE (16-BIT DATA PINS)

In Full 16-Bit Multiplexed mode, the entire 16 bits of the address are multiplexed with the data pins on PMD<15:0>. Pins PMA<0> and PMA<1> provide Address Latch Low enable PMALL and Address Latch High enable PMALH strobes, respectively, and at the same time. Pins PMA<13:2> are not used as address pins and can be used as general purpose I/O pins. In the event address bits PMA15 or PMA14 are configured as Chip Selects, the corresponding address bits PMADDR<15> and PMADDR<14> are automatically forced = 0. Full 16-Bit Multiplexed mode is selected by configuring bits:

ADRMUX<1:0>(PMCON<12:11>) = 11

PIC32MX3XX/4XX

FIGURE 20-6: FULL MULTIPLEXED ADDRESSING (16-BIT BUS)

20.2.16 ADDRESSING CONSIDERATIONS

PMCS2 and PMCS1 Chip Select pins share functionality with address lines A15 and A14. It is possible to enable both PMCS2 and PMCS1 as Chip Selects, or enable only PMCS2 as a Chip Select, allowing PMCS1 to function strictly as address line A14. It is not possible to enable only PMCS1. When configured as Chip Selects, a 1 must be written into bit position 15 or 14 of the PMADDR register in order for PMCS2 or PMCS1 to become active during a read or write operation. Failing to write a 1 to PMCS2 or PMCS1 does not prevent address pins PMA<13:0> from being active as the specified address appears, however, no Chip Select signal will be active.

Note:			Auto-Incre and PMCS			
			be controlle		•	
	softwar	e by	writing	to	'1'	to
	PMADI	DR<15:1	4> explicitl	у.		

Disabling one or both Chip Selects PMCS2 and PMCS1 makes these pins available as address lines A15 and A14.

Full Multiplexed In mode. address bits PMADDR<15:0> are multiplexed with the data bus and in the event address bits PMA15 or PMA14 are configured as Chip Selects. the corresponding PMADDR<15:14> address bits are automatically forced = 0. Disabling one or both PMCS2 and PMCS1 makes these bits available as address bits PMADDR<15:14>.

In any of the Master mode multiplexing schemes, disabling both Chip Select pins PMCS2 and PMCS1 requires the user to provide Chip Select line control through some other I/O pin under software control. See Figure 20-7.

20.3 Master Mode Timing

A PMP Master mode cycle time is defined as the number of PBCLK cycles required by the PMP to perform a read or write operation and is dependent on PBCLK clock speed, PMP address/data multiplexing modes and the number of PMP wait states, if any. Refer to the PIC32MX Family Reference Manual, PMP Chapter, for various timing diagrams. For specific setup and hold timing characteristics, refer to **Section 30.2 "AC Characteristics and Timing Parameters"** in this data sheet.

A PMP master mode read or write cycle is initiated by accessing (reading or writing) the PMDIN register. **Section TABLE 20-7: "PMP Read/Write Cycle Times"** below provides a summary of read and write PMP cycle times for each multiplex configuration.

The actual data rate of the PMP (the rate which user's code can perform a sequence of read or write operations) will be highly dependent on several factors:

- · a user's application code content
- · code optimization level
- · internal bus activity
- other factors relating to the instruction execution speed.
 - **Note:** During any Master mode read or write operation, the busy flag will always deassert 1 peripheral bus clock cycle (T_{PBCLK}) , before the end of the operation, including Wait states. The user's application must check the status of the busy flag to ensure it is = 0 before initiating the next PMP operation.

Address/Data Multiplex Configuration	ADRMUX bit	PMP Cycle Time (PBCLK cycles)		
	settings	Read	Write	
Demultiplexed	00	2	3	
Partial Multiplex	01	5	6	
Full Multiplexed (8-bit data)	10	8	9	
Full Multiplexed (16-bit data)	11	5	6	

TABLE 20-7: PMP READ/WRITE CYCLE TIMES

Note: Wait states are not enabled

20.3.1 MASTER PORT CONFIGURATION

The Master mode configuration is determined primarily by the interface requirements to the external device. Address multiplexing, control signal polarity, data width and Wait states typically dictate the specific configuration of the PMP master port.

The following illustrates example settings for Master Mode 2 operation:

- Select Master Mode 2 -MODE<1:0> (PMMODE<9:8>) = 10.
- Select 16-Bit Data mode -MODE16 (PMMODE<10>) = 1.
- Select partial multiplexed addressing -ADRMUX<1:0> (PMCON<12:11>) = 01.
- Select auto-address increment -INCM<1:0> (PMMODE<12:11>) = 01.
- Enable Interrupt Request mode -IRQM<1:0> (PMMODE<14:13>) = 01.
- Enable PMRD strobe -PTRDEN (PMCON<8>) = 1.
- Enable PMWR strobe -PTWREN (PMCON<9>) = 1.
- Enable PMCS2 and PMCS1 Chip Selects -CSF (PMCON<7:6>) = 10.
- Select PMRD "active-low" pin polarity -RDSP (PMCON<0>) = 0.

- Select PMWR "active-low" pin polarity -WRSP (PMCON<1>) = 0.
- Select PMCS2, PMCS1 "active-low" pin polarity -CS2P (PMCON<4>) = 0 and CS1P (PMCON<3>) = 0.
- Select 1 wait cycle for data setup -WAITB<1:0>(PMMODE<7:6>) = 00.
- Select 2 wait cycles to extend PMRD/PMWR WAITM<3:0>(PMMODE<5:2>) = 01.
- Select 1 wait cycle for data hold -WAITB<1:0>(PMMODE<1:0>) = 00.
- Enable upper 8 PMA<15:8> address pins -PMAEN<15:8> = 1 (lower 8 can be used as general purpose I/O).

20.3.2 MASTER PORT INITIALIZATION

The Master mode initialization properly prepares the PMP port for communicating with an external device.

The following steps should be performed to properly configure the PMP port:

- If interrupts are used, disable the PMP interrupt by clearing the interrupt enable bit PMPIE (IEC1<2>) = 0.
- 2. Stop and reset the PMP module by clearing the control bit ON (PMCON<15>) = 0.
- 3. Configure the desired settings in the PMCON, PMMODE and PMAEN control registers.

- 4. If interrupts are used:
 - a) Clear interrupt flag bit PMPIF (IFS1<2>) = 0.
 - b) Configure the PMP interrupt priority bits PMPIP<2:0> (IPC7<4:2>) and interrupt sub priority bits PMPIS (IPC7<1:0>.
 - c) Enable PMP interrupt by setting interrupt enable bit PMPIE = 1.
- 5. Enable the PMP master port by setting control bit ON = 1.

IEC1CLR = 0x0004;	//Disable PMP int
PMCON = 0x0BC0;	//Stop and Configure
PMMODE = 0x2A04;	//Config PMMODE reg
PMAEN = 0xFF00;	//Config PMAEN reg
IPC7SET = 0x001C;	//Priority level=7
IPC7SET = 0x0003;	//subpriority=3 //Same as //IPC7SET=0x001F
IFS1CLR = 0x0004;	//Clear PMP flag
IEC1SET = 0x0004;	//Enable PMP int
PMCONSET = 0x8000;	//Enable PMP
PMADDR = 0x4000;	//Set external address
PMDIN = 0x1234;	//Write to device

EXAMPLE 20-1: PARALLEL MASTER PORT INITIALIZATION

20.3.3 READ OPERATION

To perform a read on the parallel bus, the user reads the PMDIN register. The effect of reading the PMDIN register retrieves the current value and causes the PMP to activate the Chip Select lines and the address bus. The read line PMRD is strobed and the new data is latched into the PMDIN register, making it available for the next time the PMDIN register is read. Note: The read data obtained from the PMDIN register is actually the read value from the previous read operation. Hence, the first user read will be a dummy read to initiate the first bus read and fill the read register. Also, the requested read value will not be ready until after the BUSY bit is observed low. Therefore, in a back-to-back read operation, the data read from the register will be the same for both reads. The next read of the register will yield the new value.

Refer to the PIC32MX3XX/4XX Reference Manual for a detailed description of the read operation and illustrated example.

20.3.4 WRITE OPERATION

To perform a write onto the parallel port, the user writes to the PMDIN register (same register used for a read operation). This causes the module to first activate the Chip Select lines and the address bus. The write data from the PMDIN register is placed onto the PMD data bus and the write line PMPWR is strobed.

20.3.5 PARALLEL MASTER PORT STATUS

In addition to the PMP interrupt, a BUSY bit is provided to indicate the status of the module. This bit is only used in Master modes.

While any read or write operation is in progress, the BUSY bit is set for all but the very last peripheral bus cycle of the operation. While the bit is set, any request by the user to initiate a new operation will be ignored (i.e., writing or reading the PMDIN register will not initiate either a read nor a write).

EXAMPLE 20-2: POLLING THE BUSY FLAG

```
/*An generic C example PMP write function
    utilizing the BUSY bit.
*/
pmpWrite(unsigned int value)
{
    while(PMMODE & 0x8000); // PMP busy?
    PMDIN = value; // perform write
}
/*An MPLAB C32 example PMP write function
    utilizing BUSY bit.
*/
pmpWrite(unsigned int value)
{
    while(PMMODEbits.BUSY); // PMP busy?
    PMDIN = value; // perform write
}
```

In most applications, the PMP's Chip Select pin(s) provide the Chip Select interface and are under the timing control of the PMP module. However, some applications may require the PMP Chip Select pin(s) not be configured as a Chip Select, but as a high-order address line, such as PMA<14> or PMA<15>. In this situation, the application's Chip Select function must be provided by an available I/O port pin under software control. In these cases, it is especially important that the user's software poll the BUSY bit to ensure any read or write operation is complete before de-asserting the software controlled Chip Select.

The following example illustrates a common technique.

If a large number of wait-states are used, or if the PBCLK clock is operating slower than the SYSCLK clock, it is possible for the PMP module to be in the process of completing a read or write operation when the next CPU instruction is attempting to read or write the PMP module. For this reason, it is highly recommended that the PMP's BUSY bit be checked prior to any read or write operation and any user operation that modifies the PMADDR address register. See the following code example.

Note: During any Master mode read or write operation, the busy flag will always deassert 1 peripheral bus clock cycle (T_{PBCLK}), before the end of the operation, including Wait states.

PIC32MX3XX/4XX

EXAMPLE 20-3: POLLING THE BUSY FLAG AND SOFTWARE CONTROLLED CHIP SELECT

```
/* An generic C example PMP write function
   utilizing PORTD.RD1 as an active low
   Chip Select and the BUSY bit.
*/
pmpWrite(unsigned int value)
{
   PORTDCLR = 0x0002; //CS enabled
   while(PMMODE & 0x8000); // PMP busy?
   PMDIN = value; //perform write
   while (PMMODE & 0x8000); //wait for PMP
   PORTDSET = 0x0002; //CS disabled
}
/* An MPLAB C32 example PMP write function
   utilizing PORTD.RD1 as an active low
   Chip Select and the BUSY bit.
*/
pmpWrite(unsigned int value)
{
   PORTDCLR = 0x0002; //CS enabled
   while(PMMODEbits.BUSY); // PMP busy?
   PMDIN = value; // perform write
   while(PMMODEbits.BUSY); // wait for PMP
   PORTDSET = 0x0002; //CS disabled
}
```

20.3.6 SLAVE MODE

20.3.6.1 Considerations for Slave Mode

- Do not enable or disable the module during any read or write operation
- Because of the asynchronous nature of the read and write operations, it is highly recommended that the user rely on the PSP status bits prior to any read or write operation.

The PMP module provides 8-Bit (byte) legacy Parallel Slave Port functionality as well as new Buffered and Addressable Slave modes.

20.3.7 MODE SELECTION

The three Master modes are selected using MODE<1:0> bits (PMCON<9:8>). Legacy Slave mode is selected by configuring MODE<1:0> bits = 00; Buffered and Addressable Slave modes are selected by configuring MODE<1:0> = 01. Additionally, Buffered Slave mode requires bits INCM<1:0> (PMMODE<12:11>) = 11.

TABLE 20-8: Slave Mode Selection

Slave Mode	PMCON MODE<1:0>	PMMODE INCM<1:0>
Legacy	00	x = don't care
Buffered	00	11
Addressable	01	x = don't care

All Slave modes support 8-bit data only and the associated module control pins are automatically dedicated to the module when any of these modes are selected. The user only need to configure the polarity of the PMCS1, PMRD and PMWR signals.

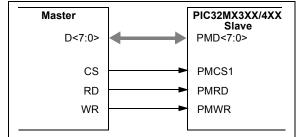

TABLE 20-9:Slave Mode Pin Polarity
Configuration

CONTROL PIN	PMCON Control Bit	Active-High Select	Active-Low Select
PMRD	RDSP	1	0
PMWR	WRSP	1	0
PMCS1	CS1P	1	0

20.3.8 LEGACY PARALLEL SLAVE MODE

In Legacy Slave mode, an external device can asynchronously read and write data using the 8-bit data bus PMD<7:0>, the read PMRD, write PMWR, and chip-select PMCS1 inputs.

Figure 20-8: Legacy Slave Mode Interface

20.3.9 LEGACY SLAVE CONFIGURATION

The Legacy Slave mode configuration is determined automatically and dedicated to the PSP module when the Legacy Slave mode is selected. The user only need to configure the polarity of the PMCS1, PMRD and PMWR signals.

The following example illustrates which control bits are to be set for Legacy Slave mode configuration:

- Configure Legacy Slave mode bits -MODE<1:0> (PMMODE<9:8>) = 00
- Select PMRD "active-low" pin polarity -RDSP (PMCON<0>) = 0.
- Select PMWR "active-low" pin polarity -WRSP (PMCON<1>) = 0.
- Select PMCS2, PMCS1 "active-low" pin polarity -CS2P (PMCON<4>) = 0 and CS1P (PMCON<3>) = 0.

20.3.10 SLAVE PORT INITIALIZATION

The Legacy Slave mode initialization properly prepares the PMP port for communicating with an external master device.

- If interrupts are used, disable the PMP interrupt by clearing the interrupt enable bit PMPIE (IEC1<2>) = 0.
- 2. Stop and reset the PMP module by clearing the control bit ON (PMCON<15>) = 0.
- 3. Configure the desired settings in the PMCON and PMMODE control registers.
- 4. If interrupts are used:
 - a) Clear interrupt flag bit PMPIF (IFS1<2>) = 0.
 - b) Configure the PMP interrupt priority bits PMPIP<2:0> (IPC7<4:2>) and interrupt sub priority bits PMPIS (IPC7<1:0>.
 - c) Enable PMP interrupt by setting interrupt enable bit PMPIE = 1.
- 5. Enable the PMP slave port by setting control bit ON = 1.

PIC32MX3XX/4XX

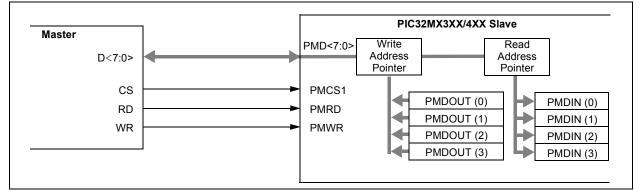

EXAMPLE 20-4:	EXAMPLE CODE: LEGACY PARALLEL SLAVE PORT INITIALIZATION
$IEC1CLR = 0 \times 0004$	//Disable PMP int
$PMCON = 0 \times 0000$	//Stop and Configure
$PMMODE = 0 \times 0000$	//Config PMMODE
IPC7SET = 0x001C;	//Priority level=7
IPC7SET = 0x0003;	<pre>//subpriority =3 //Same as //IPC7SET=0x001F</pre>
IFS1CLR = 0x0004	; //Clear PMP flag
$IEC1SET = 0 \times 0004$; //Enable PMP int
PMCONSET = 0x8000	; //Enable PMP

EXAMPLE 20-4: EXAMPLE CODE: LEGACY PARALLEL SLAVE PORT INITIALIZATION

20.3.11 Buffered Slave Mode

Buffered Parallel Slave Port mode is functionally identical to the Legacy Parallel Slave Port mode with one exception: the implementation of 4-level read and write buffers. Buffered Slave mode is enabled by setting the PMMODE<INCM1:INCM0> bits to '11'. When the Buffered mode is active, the module uses the PMDIN register as write buffers and the PMDOUT register as read buffers, with respect to the master device. Each register is divided into four 8-bit buffer registers, four read buffers in PMDOUT and four write buffers in PMDIN. Buffers are numbered 0 through 3, starting with the lower byte <7:0> and progressing upward through the high byte <31:24>.

FIGURE 20-9: PARALLEL MASTER/SLAVE CONNECTION BUFFERED

20.3.12 BUFFERED SLAVE CONFIGURATION

The Buffered Slave mode configuration is determined automatically and dedicated to the PMP module when the Buffered Slave mode is selected. The user only need to configure the polarity of the PMCS1, PMRD and PMWR signals.

The following example illustrates which control bits are to be set for Buffered Slave mode configuration:

- Configure Buffered Slave mode bits -MODE<1:0> (PMMODE<9:8>) = 00 and INCM<1:0> (PMMODE<12:11>) = 11.
- Select PMRD "active-low" pin polarity -RDSP (PMCON<0>) = 0.
- Select PMWR "active-low" pin polarity -WRSP (PMCON<1>) = 0.
- Select PMCS2, PMCS1 "active-low" pin polarity -CS2P (PMCON<4>) = 0 and CS1P (PMCON<3>) = 0.

20.3.13 BUFFERED SLAVE MODE INITIALIZATION

The Buffered Slave mode initialization properly prepares the PSP port for communicating with an external master device.

The following steps should be performed to properly configure the PSP port:

- If interrupts are used, disable the PMP interrupt by clearing the interrupt enable bit PMPIE (IEC1<2>) = 0.
- Stop and reset the PMP module by clearing the control bit ON (PMCON<15>) = 0.

- 3. Configure the desired settings in the PMCON and PMMODE control registers.
- 4. If interrupts are used:
 - a) Clear interrupt flag bit PMPIF (IFS1<2>) = 0.
 - b) Configure the PMP interrupt priority bits PMPIP<2:0> (IPC7<4:2>) and interrupt sub priority bits PMPIS (IPC7<1:0>.
 - c) Enable PSP interrupt by setting interrupt enable bit PMPIE = 1.
- 5. Enable the PMP slave port by setting control bit ON = 1.

PIC32MX3XX/4XX

EXAMPLE 20-5: BUFFERED PARALLEL SLAVE MODE INITIALIZATION

$IEC1CLR = 0 \times 0004$	//Disable PMP
$PMCON = 0 \times 0000$	//Stop and Configure
PMMODE = 0x1800	//Configure PMMODE
IPC7SET = 0x001C;	//Priority level=7
IPC7SET = 0x0003;	//subpriority=3 //Same as //IPC7SET=0x001F
IFS1CLR = 0x0004;	//Clear PMP flag
IEC1SET = 0x0004;	//Enable PMP int
PMCONSET = 0x8000;	//Enable PMP

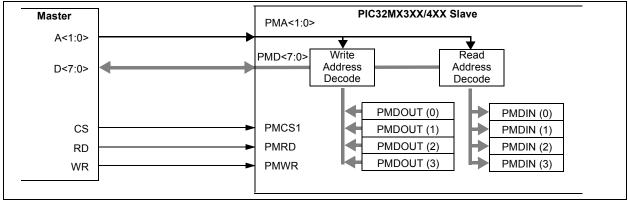

20.3.14 ADDRESSABLE SLAVE MODE

In the Addressable Parallel Slave Port mode, the module is configured with two extra inputs, PMA<1:0>. This makes the 4-byte buffer space directly addressable as fixed pairs of read and write buffers. As with Buffered Legacy mode, data is output from register PMDOUT and is input to register PMDIN. Table 20-10 shows the address resolution for the incoming address to the input and output registers.

TABLE 20-10: SLAVE MODE BUFFER ADDRESSES

PMA<1:0>	Output Register PMDOUT (Buffer)	Input Register PMDIN (Buffer)
00	<7:0> (0)	<7:0> (0)
01	<15:8> (1)	<15:8> (1)
10	<23:16> (2)	<23:16> (2)
11	<31:24> (3)	<31:24> (3)

FIGURE 20-10: PARALLEL MASTER/SLAVE CONNECTION ADDRESSABLE BUFFER

20.3.15 ADDRESSABLE SLAVE CONFIGURATION

The Addressable Slave mode configuration is determined automatically and dedicated to the PSP module when the Addressable Slave mode is selected. The user only need to configure the polarity of the PMCS1, PMRD and PMWR signals.

The following example illustrates which control bits are to be set for Addressable Slave mode configuration:

 Configure Addressable Slave mode bits – MODE<1:0> (PMMODE<9:8>) = 01

- Select PMRD "active-low" pin polarity RDSP (PMCON<0>) = 0
- Select PMWR "active-low" pin polarity WRSP (PMCON<1>) = 0
- Select PMCS2, PMCS1 "active-low" pin polarity CS2P(PMCON<4>)=0 and CS1P(PMCON<3>)=0

20.3.16 ADDRESSABLE SLAVE PORT INITIALIZATION

The Addressable Slave mode initialization properly prepares the PSP port for communicating with an external master device.

The following steps should be performed to properly configure the PSP port:

- If interrupts are used, disable the PMP interrupt by clearing the interrupt enable bit PMPIE (IEC1<2>) = 0.
- 2. Stop and reset the PMP module by clearing the

control bit ON (PMCON<15>) = 0.

- 3. Configure the desired settings in the PMCON and PMMODE control registers.
- 4. If interrupts are used:
 - a) Clear interrupt flag bit PMPIF (IFS1<2>) = 0.
 - b) Configure the PMP interrupt priority bits PMPIP<2:0> (IPC7<4:2>) and interrupt sub priority bits PMPIS (IPC7<1:0>.
 - c) Enable PSP interrupt by setting interrupt enable bit PMPIE = 1.
- Enable the PMP slave port by setting control bit ON = 1.

EXAMPLE 20-6: ADDRESSABLE PARALLEL SLAVE PORT INITIALIZATION

IEC1CLR = 0x0004	//Disable PMP int
$PMCON = 0 \times 0000$	//Stop and Configure
PMMODE = 0x0100	//Config PMMODE
IPC7SET = 0x001C;	//Priority level=7
IPC7SET = 0x0003;	//subpriority=3
	//Same as
	//IPC7SET=0x001F
IFS1CLR = 0x0004;	//Clear PMP int flag
IEC1SET = 0x0004;	//Enable PMP int
PMCONSET = 0x8000;	//Enable PMP module

20.4 PMP Interrupts

The PMP module has the ability to generate the following types of interrupts reflecting the events that occur during data transfers.

Master mode:

• Interrupt on every read and write operation.

Legacy Slave mode:

· Interrupt on every read and write byte

Buffered Slave mode:

- · Interrupt on every read and write byte
- Interrupt on read or write byte of Buffer 3 (PMDOUT<31:24>)

Addressable Slave mode:

- Interrupt on every read and write byte
- Interrupt on read or write byte of Buffer 3 (PMDOUT<31:24>), PMA<1:0> = 11

The PMP module is enabled as a source of interrupt using the PMP interrupt enable bit:

• PMPIE (IEC1<2>).

The interrupt priority level and subpriority level bits must also be configured:

- PMPIP<2:0> (IPC7<4:2>)
- PMPIS<1:0> (IPC7<1:0>)
- The PMP interrupt status flag, PMPIF (IFS1<2>) is typically cleared by the user's software in the ISR.

Below is a partial code example of an ISR.

Note: It is the user's responsibility to clear the corresponding interrupt flag bit before returning from an ISR.

EXAMPLE 20-7: PMP MODULE INTERRUPT INITIALIZATION

```
The following code example illustrates a PMP interrupt configuration.
   When the PMP interrupt is generated, the CPU will branch to the vector
   assigned to PMP interrupt.
*/
   // Configure PMP for desired mode of operation
   // Configure the PMP interrupts
                        // Set priority level=5
   IPC7SET = 0 \times 0014;
   IPC7SET = 0 \times 0003;
                          // Set subpriority level=3
                          // Could have also done this in single
                          // operation by assigning IPC7SET = 0x0017
   IFS1CLR = 0 \times 0002;
                       // Clear the PMP interrupt status flag
   IEC1SET = 0x0002; // Enable PMP interrupts
   PMCONSET = 0 \times 8000;
                       // Enable PMP module
```

```
EXAMPLE 20-8: PMP ISR
```

```
/*
The following code example demonstrates a simple interrupt
service routine for PMP interrupts. The user's code at this
vector should perform any application specific operations and must
clear the PMP interrupt status flag before exiting.
*/
void _IRQ(_PMP_VECTOR, ipl3) PMP_Interrupt_ISR(void)
{
    ... perform application specific operations in response to the interrupt
IFS1CLR = 0x00002; // Be sure to clear the PMP interrupt status
    // flag before exiting the service routine.
}
```

20.5 I/O Pin Control

TABLE 20-11: REQUIRED I/O PIN RESOURCES FOR MASTER MODES

I/O Pin Name	De- multiplex	Partial Multiplex	Full Multiplex	Functional Description
PMPCS2 / PMA15	Yes ⁽²⁾	Yes ⁽²⁾	Yes ⁽²⁾	PMP Chip Select 2 / Address A15

PMA<13:2>	Yes ⁽²⁾	Yes ⁽³⁾	No ⁽¹⁾	PMP Address A13A2
PMA1 / PMALH	No ⁽¹⁾	No ⁽¹⁾	Yes ⁽⁴⁾	PMP Address A1 / Address Latch High
PMA0 / PMALL	No ⁽¹⁾	Yes ⁽²⁾	Yes ⁽⁴⁾	PMP Address A0 / Address Latch Low
PMRD / PMWR	Yes	Yes	Yes	PMP Read / Write Control
PMWR / PMENB	Yes	Yes	Yes	PMP Write / Enable Control
PMD<15:0>	Yes ⁽⁵⁾	Yes ⁽⁵⁾	Yes ⁽⁵⁾	PMP Bidirectional Data Bus D15D0

Note 1: "No" indicates the pin is not required and is available as a general purpose I/O pin when the corresponding PMAEN bit is cleared, = 0.

- 2: Depending on the application, not all PMA<15:0> or CS2, CS1 may be required.
- 3: When Partial Multiplex mode is selected (ADDRMUX<1:0> = 01), the lower 8 Address lines are multiplexed with PMD<7:0>, PMA<0> becomes (PMALL) and PMA<7:1> are available as general purpose I/O pins.
- 4: When Full Multiplex mode is selected (ADDRMUX<1:0> = 10 or 11), all 16 Address lines are multiplexed with PMD<15:0>, PMA<0> becomes (PMALL), PMA<1> becomes (PMALH) and PMA<13:2> are available as general purpose I/O pins.
- 5: If MODE16 = 0, then only PMD<7:0> are required. PMD<15:8> are available as general purpose I/O pins.
- **6:** Data pins PMD<15:0> are available on 100-pin PIC32MX3XX/4XX devices and larger. For all other device variants, only pins PMD<7:0> are available.

When enabling any of the PMP module for Slave mode operations, the PMPCS1, PMRD, PMWR control pins, PMD<7:0> data pins and PMA<1:0> address pins are

automatically enabled and configured. The user is however responsible for selecting the appropriate polarity for these control lines.

I/O Pin Name	Legacy	Buffered	Addressable	Functional Description
PMPCS1 / PMA14	Yes	Yes	Yes	Chip Select
PMA1 / PMALH	No ⁽¹⁾	No ⁽¹⁾	Yes	Address A1
PMA0 / PMALL	No ⁽¹⁾	No ⁽¹⁾	Yes	Address A0
PMRD / PMWR	Yes	Yes	Yes	Read Control
PMWR / PMENB	Yes	Yes	Yes	Write Control
PMD<7:0>	Yes ⁽²⁾	Yes ⁽²⁾	Yes ⁽²⁾	Bidirectional Data Bus D7D0

TABLE 20-12: REQUIRED I/O PIN RESOURCES FOR SLAVE MODES

Note 1: "No" indicates the pin is not required and is available as a general purpose I/O pin when the corresponding PMAEN bit is cleared, = 0.

2: Slave modes use PMD<7:0> only. Pins PMD<15:8> are available as general purpose I/O pins. Control bit MODE16 (PMMODE<10>) is ignored.

20.5.1 I/O PIN CONFIGURATION

The following table provides a summary of settings required to enable the I/O pin resources used with this module. The PMAEN register controls the functionality of pins PMA<15:0>. Setting any PMAEN bit = 1 configures the corresponding PMA pin as an address line. Those bits set = 0 remain as general purpose I/O pins.

© 2008 Microchip Technology Inc.

		Require	ed Settings for Mo Pin Control	dule			
I/O Pin Name	Required ⁽¹⁾	Module Control	Bit Field	TRIS	Pin Type	Buffer Type ⁽²⁾	Description
PMPCS2 / PMA15	Yes	ON	CSF<1:0>, CS2, PTEN15	—	0	ST/TTL	PMP Chip Select 2 / Address A15

PMD<15:0>	Yes	ON	MODE16, ADRMUX<1:0>		I,O	ST/TTL	PMP Bidirectional Data Bus D15D0

TABLE 20-13: I/O PIN CONFIGURATION

Legend: TTL = TTL compatible input or output, ST = Schmitt Trigger input with CMOS levels, I = Input, O = Output

Note 1: Depending on the PMP mode and the user's application, these pins may not be required. If not enabled, these pins can be used as general purpose I/O.

2: Default buffer type is ST.

21.0 REAL-TIME CLOCK AND CALENDAR (RTCC)

Note: This data sheet summarizes the features of the PIC32MX3XX/4XX family of devices. It is not intended to be a comprehensive reference source. Refer to the *"PIC32MX Family Reference Manual"* (DS61132) for a detailed description of this peripheral.

The PIC32MX3XX/4XX Real-Time Clock and Calendar (RTCC) module is intended for applications where accurate time must be maintained for extended periods of time with minimal or no CPU intervention. Low-power optimization provides extended battery lifetime while keeping track of time.

Following are some of the key features of this module:

- · Time: Hours, Minutes and Seconds
- 24-Hour Format (Military Time)
- Visibility of One-Half-Second Period
- Provides Calendar: Weekday, Date, Month and Year

- Alarm Intervals are configurable for Half a Second, One Second, 10 Seconds, One Minute, 10 Minutes, One Hour, One Day, One Week, One Month and One Year
- · Alarm Repeat with Decrementing Counter
- Alarm with Indefinite Repeat: Chime
- Year Range: 2000 to 2099
- Leap Year Correction
- BCD Format for Smaller Firmware Overhead
- Optimized for Long-Term Battery Operation
- · Fractional Second Synchronization
- User Calibration of the Clock Crystal Frequency with Auto-Adjust
- Calibration Range: ±0.66 Seconds Error per Month
- Calibrates up to 260 ppm of Crystal Error
- Requirements: External 32.768 kHz Clock Crystal
- Alarm Pulse or Seconds Clock Output on RTCC pin

REGISTER 21	I-1: RTCCON: RTC CONTROL REGISTER ⁽¹⁾ (CONTINUED)
bit 5-4	Reserved: Maintain as '0'; ignore read
bit 3	RTCWREN: RTC Value Registers Write Enable bit
	 1 = RTC Value registers can be written to by the user 0 = RTC Value registers are locked out from being written to by the user Note: The RTCWREN bit can be set only when the write sequence is enabled. The register can be written to a '0' at any time.
bit 2	RTCSYNC: RTCC Value Registers Read Synchronization bit
	 1 = RTC Value registers can change while reading due to a roll over ripple that results in an invalid data read. If the register is read twice and results in the same data, the data can be assumed to be valid. 0 = RTC Value registers can be read without concern about a roll over ripple
bit 1	HALFSEC: Half-Second Status bit
	 1 = Second half period of a second 0 = First half period of a second Note: This bit is read-only. It is cleared to '0' on a write to the SECONDS register.
bit 0	RTCOE: RTCC Output Enable bit 1 = RTCC clock output enabled – clock presented onto an I/O 0 = RTCC clock output disabled Note: This bit is ANDed with ON (RTCCON<15>) to produce the effective RTCC output enable.

Note 1: This register is only reset by Power-on Reset (POR).

21.2 Clock Calendar Mode

The PIC32MX3XX/4XX RTCC module provides clock and

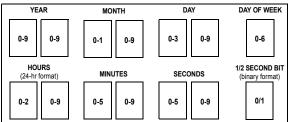

calendar functions with the following features:

- 100-year clock and calendar with automatic leap year detection.
- Clock range from 00:00:00 (midnight) on January 1, 2000 to 23:59:59 on December 31, 2099.
- Clock granularity of one second with half-second visibility to the user.

21.2.1 RTCC CONFIGURATION

The RTCTIME and RTCDATE registers can be programmed with the desired time and date numeric values expressed in Binary Coded Decimal (BCD) format. This simplifies users' firmware as each of the digit values is contained within its own 4-bit value (see Figure 21-2).

FIGURE 21-2: TIMER DIGIT FORMAT

The user can configure the current time by simply writing the desired year, month, day, hour, minutes and seconds to the RTCTIME and RTCDATE registers. However, these registers are write-protected and require a special "unlock" sequence to be performed prior to writing to these registers. Additionally, the user should verify that the RTCSYNC bit (RTCCON<2>) = 0 (safe to access registers) for any read or write operations.

Refer to **Section 21.2.3** "Write Lock" and Example 21-3

21.2.2 SAFETY WINDOW FOR REGISTER READS AND WRITES

The RTCTIME and RTCDATE registers can be safely accessed when the RTCC module is disabled (ON bit (RTCCON<15>) = 0). However, when the RTCC module is enabled (ON bit = 1), the module provides a single RTCSYNC bit (RTCCON<2>) that the user must use to determine when it is safe to read and update the time and date registers.

The RTCSYNC bit indicates a time window during which the RTCC time registers (RTCTIME, RTCDATE) are not about to be updated and can be safely read and written.

For read or write operations, the registers can be safely accessed by the CPU when RTCSYNC = 0.

For a read operation when RTSYNC = 1, the user must employ a firmware solution to assure that the data read did not fall on an update boundary, resulting in an invalid or partial read. For example, reading and comparing a Timer register value twice can ensure in code that the register read did not span an RTCC clock update.

Write operations to the Time and Date registers should not be performed when RTCSYNC = 1.

Refer to Example 21-1 and Example 21-2.

EXAMPLE 21-1: UPDATING THE RTCC TIME AND DATE

```
The following code example will update the RTCC time and date.
* /
   // assume the secondary oscillator is enabled and ready, i.e.
   // OSCCON<1>=1, OSCCON<22>=1, and RTCC write is enabled i.e.
   // RTCWREN (RTCCON<3>) =1;
   unsigned long time=0x04153300;// set time to 04 hr, 15 min, 33 sec
   unsigned long date=0x06102705;// set date to Friday 27 Oct 2006
   RTCCONCLR=0x8000;
                                 // turn off the RTCC
   while(RTCCON&0x40);
                                  // wait for clock to be turned off
   RTCTIME=time;
                                  // safe to update the time
   RTCDATE=date;
                                  // update the date
   RTCCONSET=0x8000;
                                  // turn on the RTCC
                                  // wait for clock to be turned on
   while(!(RTCCON&0x40));
                                  // can disable the RTCC write
```

EXAMPLE 21-2: UPDATING THE RTCC TIME USING THE RTCSYNC WINDOW

```
The following code example will update the RTCC time and date.
* /
   // assume RTCC write is enabled i.e. RTCWREN (RTCCON<3>) =1;
   unsigned long time=0x04153300;// set time to 04 hr, 15 min, 33 sec
   unsigned long date=0x06102705;// set date to Friday 27 Oct 2006
   // disable interrupts, critical section follows
     _asm____volatile__ ("di");
   while((RTCCON&0x4)!=0);
                                 // wait for not RTCSYNC
   RTCTIME=time:
                                 // safe to update the time
   RTCDATE=date;
                                 // update the date
   // restore interrupts, critical section ended
   __asm___volatile__ ("ei");
   // can disable the RTCC write
```

21.2.3 WRITE LOCK

In order to perform a write to any of the RTCC Time registers, the RTCWREN bit (RTCCON<3>) must be set. Setting of the RTCWREN bit is only allowed once the device level unlocking sequence has been executed. The unlocking sequence is as follows:

- 1. Suspend or disable all initiators that can access the peripheral bus and interrupt the unlock sequence. (i.e., DMA and Interrupts).
- 2. Store 0xAA996655 to the SYSKEY register.
- Store 0x556699AA to the SYSKEY register.

EXAMPLE 21-3: WRITE UNLOCK SEQUENCE

```
// assume interrupts are disabled
// assume the DMA controller is suspended
// assume the device is locked
// starting critical sequence
SYSKEY = 0xaa996655; // write first unlock key to SYSKEY
SYSKEY = 0x556699aa; // write second unlock key to SYSKEY
RTCCONSET = 0x8; // set RTCWREN in RTCCONSET
// end critical sequence
SYSKEY = 0x3333333; // perform device re-lock
// can resume the DMA controller activity
// can re-enable interrupts
```

Note: To avoid accidental writes to the RTCC time values, it is recommended that the RTCWREN bit (RTCCON<3>) is kept clear at any other time.

- 4. Set RTCWREN bit into the RTCCON register.
- 5. Perform the device relock by writing a dummy value to the SYSKEY register.
- 6. Re-enable DMA and interrupts.

Note that steps 2 through 4 must be followed exactly to unlock RTCC write operations. If the sequence is not followed exactly, the RTCWREN bit will not be set.

Refer to Example 21-3 for a "C" language implementation of the write unlock operation.

21.3 Alarm Mode

The PIC32MX3XX/4XX RTCC module provides alarm functions with the following features:

- One-time alarm
- · Repeat alarms
- Indefinite alarm repetition
- · Configurable from half-second to one year

The RTCC alarm generates an alarm event when the RTCC timer matches the masked alarm value.

The RTCC alarm functions are configurable from a half-second to one year and can repeat the alarm at preconfigured intervals. The chime feature provides indefinite repetition of the alarm.

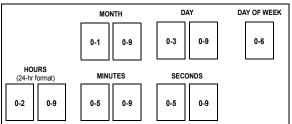

To enable the alarm feature, configure the ALRMEN bit (RTCALRM<15>) = 1. To disable the alarm feature, configure the ALRMEN bit = 0. An alarm event is generated when the RTCC timer matches the masked alarm registers.

- Note 1: Once the timer value reaches the alarm setting, one RTCC clock period will elapse prior to setting the alarm interrupt.
 - 2: IF RTCC is off (RTCCON<15> = 0) the writable fields in the RTCALRM register can be safely modified. If RTCC is ON, the write of the RTCALRM register has to be done while ALRMSYNC = 0. Not following the above steps can result in a false alarm event.
 - **3:** The same applies to the ALRMTIME and ALRMDATE registers: They can be safely modified only when ALRMSYNC = 0.

21.3.1 ALARM CONFIGURATION

The ALRMTIME and ALRMDATE registers can be programmed with the desired time and date numeric values expressed in Binary Coded Decimal (BCD) format. This simplifies users' firmware as each of the digit values is contained within its own 4-bit value (see Figure 21-3).

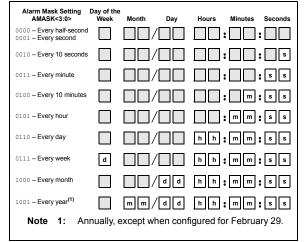

FIGURE 21-3: ALARM DIGIT FORMAT

The alarm interval selection is based on the settings of the alarm mask, AMASK (RTCALRM<11:8>). The AMASK bits determine which and how many digits of the alarm must match the RTCC clock value for the alarm event to occur (see Figure 21-4).

FIGURE 21-4:

ALARM MASK SETTINGS

21.3.2 ONE-TIME ALARM

A single, one-time alarm can be generated by configuring the Alarm Repeat Counter bits, ARPT (RTCALRM<7:0>) = 0, and the CHIME bit, (RTCALRM<14>) = 0. Once the alarm event occurs, the ALRMEN bit is automatically cleared in hardware, disabling future alarms. The user must re-enable this bit for any new alarm configuration.

It is suggested to read and verify the Alarm Sync bit, ALRMSYNC (RTCALRM<12>) = 0, before performing the following configuration:

- Disable Alarm ALRMEN (RTCALRM<15>) = 0.
- Disable Chime CHIME (RTCALRM<14>) = 0.
- Clear Alarm Repeat Counter ARPT (RTCALRM<7:0>) = 0.

The remaining bits are shown with example configurations and may be configured as desired:

- Configure alarm date and time Load ALRMDATE and ALRMTIME registers with the desired alarm date/time values.
- Configure mask Load the desired AMASK value.
- Enable Alarm ALRMEN (RTCALRM<15>) = 0.

Refer to Example 21-4

EXAMPLE 21-4: CONFIGURING THE RTCC FOR A ONE-TIME ALARM

```
The following code example will update the RTCC one-time alarm.
   Assumes the interrupts are disabled.
*/
   unsigned long alTime=0x16153300;// set time to 04 hr, 15 min, 33 sec
   unsigned long alDate=0x06102705;// set date to Friday 27 Oct 2006
                                   // turn off the alarm, chime and alarm repeats; clear
                                   // the alarm mask
   while(RTCALRM&0x1000);
                                   // wait ALRMSYNC to be off
   RTCALRMCLR=0xCFFF;
                                  // clear ALRMEN, CHIME, AMASK and ARPT;
   ALRMTIME=alTime;
   ALRMDATE=alDate;
                                   // update the alarm time and date
   RTCALRMSET=0x8000|0x0000600;
                                 // re-enable the alarm, set alarm mask at once per day
```

21.3.3 REPEAT ALARM

A repeat alarm can be generated by configuring the Alarm Repeat Counter bits, ARPT (RTCALRM<7:0>) = 0x00 to 0xFF (0 to 255), and the CHIME bit (RTCALRM<14>) = 0. Once the alarm is enabled and an alarm event occurs, the ARPT count is decremented by one. Once the register reaches 0, the alarm will be generated one last time; after which point, ALRMEN bit is cleared automatically and the alarm will turn off. The user must re-enable this bit for any new alarm configuration.

Note: An alarm event is generated when ARPT bits are = 0x00.

It is recommended to read and verify the Alarm Sync bit ALRMSYNC (RTCALRM<12>) = 0, before performing the following configuration steps:

- Disable alarm ALRMEN (RTCALRM<15>) = 0.
- Disable chime CHIME (RTCALRM<14>) = 0.
- Configure alarm repeat counter ARPT (RTCALRM<7:0>) = 0x00 to 0xFF.
- Configure alarm date and time Load ALRMDATE and ALRMTIME registers with the desired alarm date/time values.
- Configure mask Load the desired AMASK value.
- Enable alarm ALRMEN (RTCALRM<15>) = 0.

Refer to Example 21-5.

EXAMPLE 21-5: CONFIGURING THE RTCC FOR A TEN TIMES PER HOUR ALARM

```
The following code example will update the RTCC repeat alarm.
Assumes the interrupts are disabled.
unsigned long alTime=0x23352300; // set time to 23hr, 35 min, 23 sec
unsigned long alDate=0x06111301; // set date to Monday 13 Nov 2006
                                   \ensuremath{{\prime}}\xspace // turn off the alarm, chime and alarm repeats; clear
                                   // the alarm mask
while(RTCALRM&0x1000);
                                   // wait ALRMSYNC to be off
RTCALRMCLR=0xCFFF:
                                   // clear the ALRMEN, CHIME, AMASK and ARPT;
ALRMTIME=alTime;
ALRMDATE=alDate;
                                   // update the alarm time and date
RTCALRMSET=0x8000|0x0509;
                                   // re-enable the alarm, set alarm mask at once per hour
                                   // for 10 times repeat
```

21.3.4 INDEFINITE ALARM

An indefinite alarm can be generated by configuring the CHIME bit (RTCALRM<14>) = 1; ARPT can be any value. Once the alarm is enabled and an alarm event occurs, the ARPT count is decremented by one. ARPT rolls over from 0x00 to 0xFF and continues to decrement on each alarm event indefinitely. The ALRMEN bit is never automatically cleared in hardware. The user must clear this bit to disable the indefinite alarm.

Note: An alarm event is generated when the ARPT are = 0x00.

It is recommended to read and verify the Alarm Sync bit, ALRMSYNC (RTCALRM<12>) = 0, before performing the following configuration:

- Disable alarm ALRMEN (RTCALRM<15>) = 0.
- Enable chime CHIME (RTCALRM<14>) = 1.
- Configure alarm repeat counter ARPT (RTCALRM<7:0>) = 0 to 256.
- Configure alarm date and time Load ALRMDATE and ALRMTIME registers with the desired alarm date/time values.
- Configure mask Load the desired AMASK value.
- Enable Alarm ALRMEN (RTCALRM<15>) = 0.

Refer to Example 21-6.

EXAMPLE 21-6: CONFIGURING THE RTCC FOR INDEFINITE ALARM

```
The following code example will update the RTCC indefinite alarm.
   Assumes the interrupts are disabled.
* /
   unsigned long alTime=0x23352300; // set time to 23hr, 35 min, 23 sec
   unsigned long alDate=0x06111301; // set date to Monday 13 Nov 2006
                                     //\ turn \ off the alarm, chime and alarm repeats; clear
                                     // the alarm mask
   while(RTCALRM&0x1000);
                                     // wait ALRMSYNC to be off
   RTCALRMCLR=0xCFFF;
                                     // clear ALRMEN, CHIME, AMASK, ARPT;
   ALRMTIME=alTime;
                                     // update the alarm time and date
   ALRMDATE=alDate:
   RTCALRMSET=0xC600;
                                     // re-enable the alarm, set alarm mask at once per
                                     // hour, enable CHIME
```

21.4 RTCC Clock Source

The RTCC module is intended to be clocked by an external Real-Time Clock crystal that is oscillating at 32.768 kHz. To allow the RTCC to be clocked by an external 32.768 kHz crystal, the SOSCEN bit (OSCCON<1>) must be set (see Section 4.0 "Oscillators") or the FSOSCEN (DEVCFG1<5>) Configuration bit must be programmed to '1'. This is the only bit outside of the RTCC module with which the user must be concerned of for enabling the RTCC. The status bit, SOSCRDY (OSCCON<22>), can be used to check that the secondary oscillator is running.

Note: The RTCC does not have an exclusive access to use the SOSC oscillator. This oscillator may be used by other peripherals, such as the CPU as a low-power clock source or Timer1. Refer to the "PIC32MX3XX/4XX Reference Manual" (DS61132) regarding the operation of the Secondary Low-Power Oscillator.

21.4.1 CALIBRATION

The real-time crystal input can be calibrated using the periodic auto-adjust feature. When properly calibrated, the RTCC can provide an error of less than 0.66 seconds per month. Calibration has the ability to eliminate an error of up to 260 ppm.

The calibration is accomplished by finding the number of error clock pulses and writing this value into the CAL field of the RTCCCON register (RTCCON<9:0>). This 10-bit signed value will either be added or subtracted from the RTCC timer, once every minute. Refer to the steps below for RTCC calibration:

- 1. Using another timer resource on the device, the user must find the error of the 32.768 kHz crystal.
- 2. Once the error is known, it must be converted to the number of error clock pulses per minute.

EQUATION 21-1: ERROR CLOCKS PER MINUTE

(Ideal Frequency (32,758) – Measured Frequency) * 60 = Error Clocks per Minute

3. a) If the oscillator is *faster* than ideal (negative result from step 2), the CAL bits register value needs to be negative. This causes the specified number of clock pulses to be subtracted from the timer counter, once every minute.

b) If the oscillator is *slower* than ideal (positive result from step 2), the CAL bits register value needs to be positive. This causes the specified number of clock pulses to be added to the timer counter, once every minute.

4. Load the CAL bits (RTCCON<9:0>) with the correct value.

Writes to the CAL bits should only occur when the timer is turned off, or immediately after the rising edge of the seconds pulse (except when the seconds (RTCTIME<15:8>) field is '00' due to the possibility of the auto-adjust event).

Note: It is up to the user, to include in the error value, the initial error of the crystal drift, due to temperature and drift due to crystal aging.

A write to the seconds bits resets the state of calibration (not its value). If an adjustment just occurred, it will occur again because of the minute roll over.

EXAMPLE 21-7: UPDATING THE RTCC CALIBRATION VALUE

```
The following code example will update the RTCC calibration.
* /
   int cal=0x3FD;
                                  // 10 bits adjustment, -3 in value
   if(RTCCON&0x8000)
                                  // RTCC is ON
   {
       unsigned intt0, t1;
       do
       {
           t0=RTCTIME;
           t1=RTCTIME;
       }while(t0!=t1);
                                  // read valid time value
       if((t0\&0xFF) == 00)
                                  // we're at second 00, wait auto-adjust to be performed
       {
           while(!(RTCCON&0x2)); // wait until second half...
       }
   }
   RTCCONCLR=0x03FF0000;
                                  // clear the calibration
   RTCCONSET=cal;
```

21.5 RTCC Interrupts

The RTCC alarm can be configured to generate an interrupt at every alarm event. Refer to **Section 21.3** "**Alarm Mode**" for details regarding the various alarm events.

The RTCC module is enabled as a source of interrupts via the respective RTCC interrupt enable bit:

• RTCCIE (IEC1<15>).

The alarm interrupt is signalled by the corresponding RTCC interrupt flag bit:

• RTCCIF (IFS1<15>).

This interrupt flag must be cleared in software.

EXAMPLE 21-8: RTCC INITIALIZATION WITH INTERRUPTS

```
/*
   The following code example illustrates an RTCC initialization with interrupts enabled.
   When the RTCC alarm interrupt is generated, the cpu will jump to the vector assigned to
   RTCC interrupt.
* /
                                 // assume RTCC write is enabled i.e. RTCWREN (RTCCON<3>) =1;
   IEC1CLR=0x00008000;
                                 // disable RTCC interrupts
   RTCCONCLR=0x8000:
                                 // turn off the RTCC
   while(RTCCON&0x40);
                                 // wait for clock to be turned off
   IFS1CLR=0x00008000;
                                // clear RTCC existing event
   IPC8CLR=0x1f000000;
                                // clear the priority
   IPC8SET=0x0d000000;
                                // Set IPL=3, subpriority 1
                                 // Enable RTCC interrupts
   IEC1SET=0x00008000;
   RTCTIME=0x16153300;
                                 // safe to update time to 16 hr, 15 min, 33 sec
   RTCDATE=0x06102705;
                                 // update the date to Friday 27 Oct 2006
   RTCALRMCLR=0xCFFF;
                                // clear ALRMEN, CHIME, AMASK and ARPT;
   ALRMTIME=0x16154300;
                                // set alarm time to 16 hr, 15 min, 43 sec
   ALRMDATE=0x06102705;
                                 // set alarm date to Friday 27 Oct 2006
   RTCALRMSET=0x8000|0x00000600; // re-enable the alarm, set alarm mask at once per day
   RTCCONSET=0x8000;
                                 // turn on the RTCC
                                // wait for clock to be turned on
   while(!(RTCCON&0x40));
```

The interrupt priority level bits and interrupt subpriority level bits must be also be configured:

- RTCCIP<2:0> (IPC8<28:26>)
- RTCCIS<1:0> (IPC8<25:24>)

In addition to enabling the RTCC interrupt, an Interrupt Service Routine, ISR, is required (see Example 21-9).

Note: It is the user's responsibility to clear the corresponding interrupt flag bit before returning from an ISR.

EXAMPLE 21-9: RTCC ISR

Note: The RTCC ISR code example shows MPLAB[®] C32 C compiler specific syntax. Refer to your compiler manual regarding support for ISRs.

21.6 I/O Pin Control

Enabling the RTCC modules configures the I/O pin direction. When the RTCC module is enabled, configured and the output enabled, the I/O pin direction is properly configured as a digital output.

The RTCC pin can be configured to toggle at every alarm or "seconds" event. To enable the RTCC pin output, set the RTCOE bit (RTCCON<0>) = 1. To select the output to toggle on an alarm event, configure RTSECSEL bit (RTCCON<7>) = 0. To select the output to toggle on every "seconds" update, configure RTSECSEL bit = 1.

			Required Settin	gs for Mo	dule Pin C	ontrol	
IO Pin Name	Required	Module Control	Bit Field	TRIS ⁽⁴⁾	Pin Type	Buffer Type	Description
RTCC	Yes ⁽¹⁾	ON and RTCOE ⁽²⁾	RTSECSEL = 1	х	0	CMOS	RTCC Seconds Clock
RTCC	Yes ⁽¹⁾	ON and RTCOE ⁽²⁾	RTSECSEL = 0 and ALRMEN and PIV ⁽³⁾	х	0	CMOS	RTCC Alarm Pulse

TABLE 21-3: I/O PIN CONFIGURATION FOR USE WITH RTCC MODULE

Legend: CMOS = CMOS compatible input or output; ST = Schmitt Trigger input with CMOS levels; I = Input; O = Output

Note 1: The RTCC pin is only required when seconds clock or alarm pulse output is needed. Otherwise, this pin can be used for general purpose IO and require the user to set the corresponding TRIS control register bit.

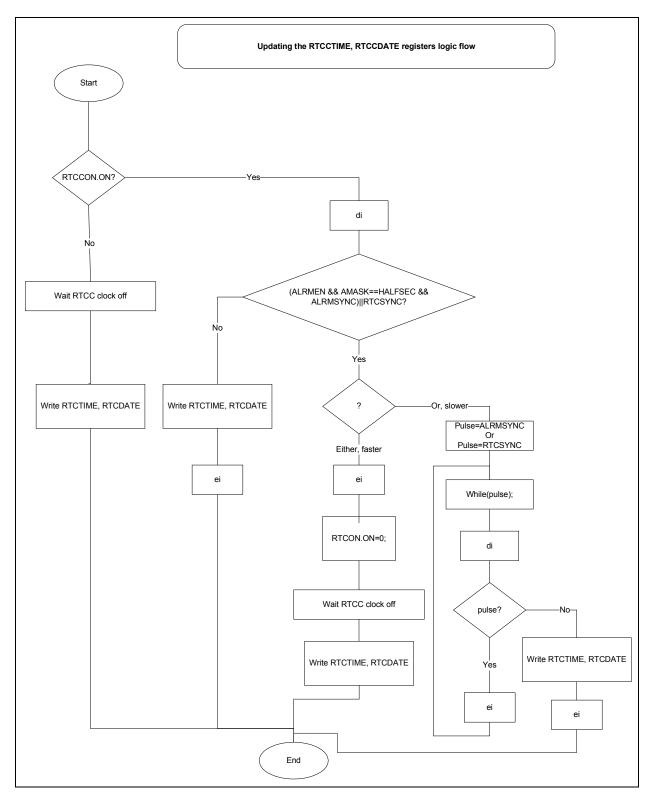

2: The ON (RTCCON<15>) and RTCOE (RTCCON<0>) bits are always required to validate the output function of the RTCC pin, either seconds clock or alarm pulse.

3: When RTSECSEL (RTCCON<7>) = 0, the RTCC pin output is the alarm pulse. If the ALRMEN (RTCALRM<15>) = 0, PIV (RTCALRM<13>) selects the value at the RTCC pin. When the ALRMEN = 1, the RTCC pin reflects the state of the alarm pulse.

4: The setting of the TRIS bit is irrelevant.

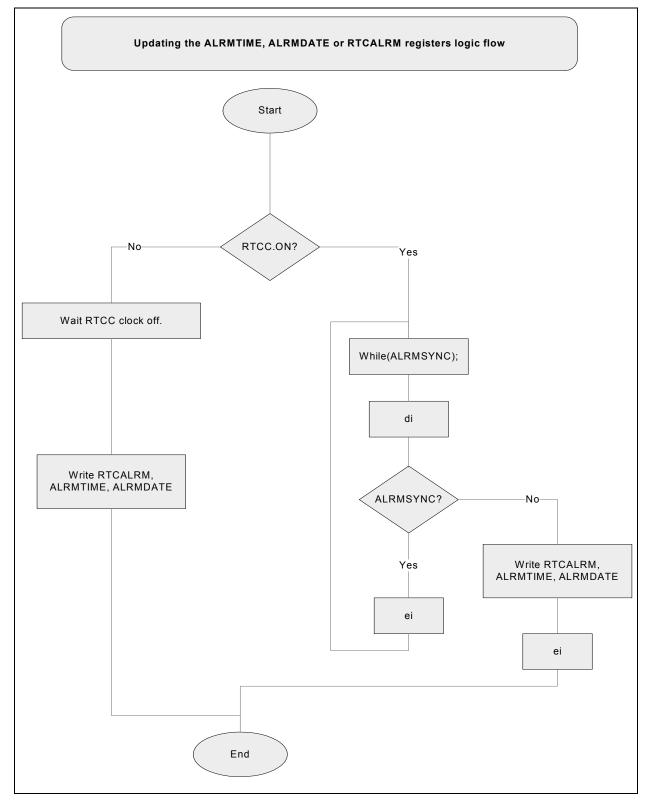

21.7 Updating the Time and Date Registers

The following flowchart explains in detail the steps that have to be performed in order to update the RTCTIME and RTCDATE registers.

21.8 Updating the Alarm Registers

The following flowchart explains in detail the steps that have to be performed in order to update the ALRMTIME, ALRMDATE and RTCALRM registers.

22.0 ANALOG-DIGITAL CONVERTER

Note: This data sheet summarizes the features of the PIC32MX3XX/4XX family of devices. It is not intended to be a comprehensive reference source. Refer to the *"PIC32MX Family Reference Manual"* (DS61132) for a detailed description of this peripheral.

The PIC32MX3XX/4XX 10-bit Analog-to-Digital (A/D) converter (or ADC) includes the following features:

- Successive Approximation Register (SAR) conversion
- Up to 500 kilo samples per second (ksps) conversion speed
- Up to 16 analog input pins
- External voltage reference input pins
- One unipolar, differential Sample-and-Hold Amplifier (SHA)
- · Automatic Channel Scan mode
- · Selectable conversion trigger source
- 16-word conversion result buffer
- Selectable Buffer Fill modes
- · Eight conversion result format options
- · Operation during CPU SLEEP and IDLE modes

A block diagram of the 10-bit ADC is shown in Figure 22-1. The 10-bit ADC can have up to 16 analog input pins, designated AN0-AN15. In addition, there are two analog input pins for external voltage reference connections. These voltage reference inputs may be shared with other analog input pins and may be common to other analog module references. The actual number of analog input pins and external voltage reference input configuration will depend on the specific PIC32MX device. Refer to the device data sheet for further details. The analog inputs are connected through two multiplexers (MUXs) to one SHA. The analog input MUXs can be switched between two sets of analog inputs between conversions. Unipolar differential conversions are possible on all channels, other than the pin used as the reference, using a reference input pin (see Figure 22-1).

The Analog Input Scan mode sequentially converts user-specified channels. A control register specifies which analog input channels will be included in the scanning sequence.

The 10-bit ADC is connected to a 16-word result buffer. Each 10-bit result is converted to one of eight, 32-bit output formats when it is read from the result buffer.

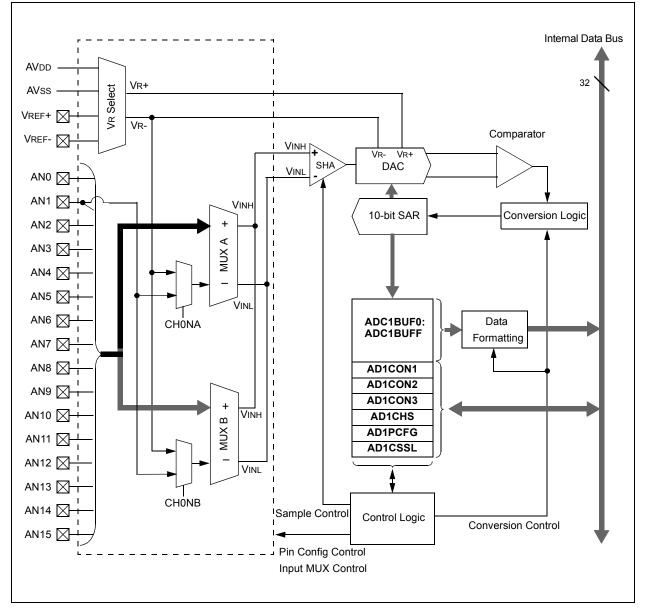

FIGURE 22-1: 10-BIT HIGH-SPEED A/D CONVERTER BLOCK DIAGRAM

22.1 Control Registers

The ADC module includes the following Special Function Registers (SFRs):

The AD1CON1, AD1CON2 and AD1CON3 registers control the operation of the ADC module.

- AD1CON1: ADC Control Register 1
 AD1CON1CLR, AD1CON1SET, AD1CON1INV:
 Atomic Bit Manipulation, Write-only Registers for
 AD1CON1.
- AD1CON2: ADC Control Register 2
 AD1CON2CLR, AD1CON2SET, AD1CON2INV:
 Atomic Bit Manipulation, Write-only Registers for
 AD1CON2.
- AD1CON3: ADC Control Register 3
 AD1CON3CLR, AD1CON3SET, AD1CON3INV:
 Atomic Bit Manipulation, Write-only Registers for
 AD1CON3.

The AD1CHS register selects the input pins to be connected to the SHA.

• AD1CHS: ADC Input Channel Select Register AD1CHSCLR, AD1CHSSET, AD1CHSINV: Atomic Bit Manipulation, Write-only Registers for AD1CHS.

The AD1PCFG register configures the analog input pins as analog inputs or as digital I/O.

 AD1PCFG: ADC Port Configuration Register AD1PCFGCLR, AD1PCFGSET, AD1PCFGINV: Atomic Bit Manipulation, Write-only Registers for AD1PCFG. The AD1CSSL register selects inputs to be sequentially scanned.

 AD1CSSL: ADC Input Scan Selection Register AD1CSSLCLR, AD1CSSLSET, AD1CSSLINV: Atomic Bit Manipulation, Write-only Registers for AD1CSSL.

The ADC module also has the following associated bits for interrupt control:

- Interrupt Request Flag Status bit (AD1IF) in IFS1: Interrupt Flag Status Register 1
- Interrupt Enable Control bit (AD1IE) in IEC1: Interrupt Enable Control Register 1
- Interrupt Priority Control bits (AD1IP<2:0>) and (AD1IS<1:0>) in IPC6: Interrupt Priority Control Register 6

22.1.1 SPECIAL FUNCTION REGISTERS ASSOCIATED WITH THE 10-BIT ADC

Table 22-1 provides a summary of all ADC-related registers, including their addresses and formats. Corresponding registers appear after the summary, followed by a detailed description of each register. All unimplemented registers and/or bits within a register read as zeros.

22.2 ADC Operation, Terminology and Conversion Sequence

This section will describe the operation the A/D converter, the steps required to configure the converter, describe the special feature of the module, and provide examples of ADC configuration with timing diagrams and charts showing the expected output of the converter.

22.2.1 OVERVIEW OF OPERATION

Analog sampling consists of two steps: acquisition and conversion (see Figure 22-2). During acquisition the analog input pin is connected to the Sample and Hold Amplifier (SHA). After the pin has been sampled for a sufficient period, the sample voltage is equivalent to the input, the pin is disconnected from the SHA to provide a stable input voltage for the conversion process. The conversion process then converts the analog sample voltage to a binary representation.

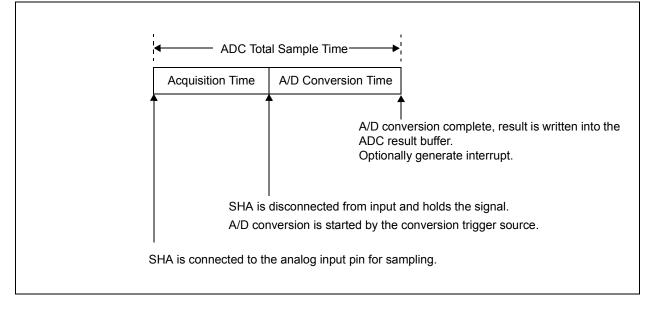

An overview of the ADC is presented in Figure 22-1. The 10-bit A/D converter has a single SHA. The SHA is connected to the analog input pins via the analog input MUXs, MUX A and MUX B. The analog input MUXs are controlled by the AD1CHS register. There are two sets of MUX control bits in the AD1CHS register. These two sets of control bits allow the two different analog input to be independently controlled. The A/D converter can optionally switch between MUX A and MUX B configurations between conversions. The A/D converter can also optionally scan through a series of analog inputs using a single MUX. Acquisition time can be controlled manually or automatically. The acquisition time may be started manually by setting the SAMP bit (AD1CON1<1>), and ended manually by clearing the SAMP in the user software. The acquisition time may be started automatically by the A/D converter hardware and ended automatically by a conversion trigger source. The acquisition time is set by the SAMC bits (AD1CON3<12:8>). The SHA has a minimum acquisition period. Refer to the device data sheet for acquisition time specifications

Conversion time is the time required for the A/D converter to convert the voltage held by the SHA. The A/D converter requires one ADC clock cycle (TAD) to convert each bit of the result, plus two additional clock cycles. Therefore, a total of 12 TAD cycles are required to perform the complete conversion. When the conversion time is complete, the result is written into one of the 16 ADC result registers (ADC1BUF0...ADC1BUFF).

The sum of the acquisition time and the A/D conversion time provides the total sample time (refer to Figure 22-2). There are multiple input clock options for the A/D converter that are used to create the TAD clock. The user must select an input clock option that does not violate the minimum TAD specification.

The sampling process can be performed once, periodically, or based on a trigger as defined by the module configuration.

FIGURE 22-2: ADC SAMPLE/CONVERSION SEQUENCE

The start time for sampling can be controlled in software by setting the SAMP control bit. The start of the sampling time can also be controlled automatically by the hardware. When the A/D converter operates in the Auto-Sample mode, the SHA is reconnected to the analog input pin at the end of the conversion in the sample/convert sequence. The auto-sample function is controlled by the ASAM control bit (AD1CON1<2>).

The conversion trigger source ends the sampling time and begins an A/D conversion or a sample/convert sequence. The conversion trigger source is selected by the control bits SSRC<2:0> (AD1CON1<7:5>). The conversion trigger can be taken from a variety of hardware sources, or can be controlled manually in software by clearing the SAMP control bit. One of the conversion trigger sources is an auto-conversion. The time between auto-conversions is set by a counter and the ADC clock. The Auto-Sample mode and auto-conversion trigger can be used together to provide endless automatic conversions without software intervention.

An interrupt may be generated at the end of each sample sequence or multiple sample sequences as determined by the value of the SMPI<3:0> (AD1CON2<5:2>). The number of sample sequences between interrupts can vary between 1 and 16. The user should note that the A/D conversion buffer holds the results of a single conversion sequence. The next sequence starts filling the buffer from the top even if the number of samples in the previous sequence was less than 16. The total number of conversion results between interrupts is the SMPI value. The total number of conversions between interrupts cannot exceed the physical buffer length.

22.3 ADC Module Configuration

Operation of the ADC module is directed through bit settings in the appropriate registers. The following instructions summarize the actions and the settings. Options and details for each configuration step are provided in subsequent sections.

- 1. To configure the ADC module, perform the following steps:
 - A-1. Configure analog port pins in AD1PCFG<15:0>, as described in Section 22.3.1 "Configuring Analog Port Pins".
 - B-1. Select the analog inputs to the ADC MUXs in AD1CHS<32:0>, as described in Section
 22.3.2 "Selecting the Analog Inputs to the ADC MUXs".
 - C-1. Select the format of the ADC result using FORM<2:0> (AD1CON1<10:8>), as described in Section 22.3.3 "Selecting the Format of the ADC Result".

- C-2. Select the sample clock source using SSRC<2:0> (AD1CON1<7:5>), as described in Section 22.3.3.1 "Selecting the Sample Clock Source".
- D-1. Select the voltage reference source using VCFG<2:0> (AD1CON2<15:13>), as described in Section 22.3.6 "Selecting the Voltage Reference Source".
- D-2. Select the Scan mode using CSCNA (AD1CON2<10>), as described in Section 22.3.7 "Selecting the Scan Mode".
- D-3. Set the number of conversions per interrupt SMPI<3:0> (AD1CON2<5:2>), if interrupts are to be used, as described in Section 22.3.8 "Setting the Number of Conversions per Interrupt".
- D-4. Set Buffer Fill mode using BUFM (AD1CON2<1>), as described in **Section** 22.3.9 "Buffer Fill Mode".
- D-5. Select the MUX to be connected to the ADC in ALTS (AD1CON2<0>), as described in Section 22.3.10 "Selecting the MUX to be Connected to the ADC (Alternating Sample Mode)".
- E-1. Select the ADC clock source using ADRC (AD1CON3<15>), as described in Section 22.3.11 "Selecting the ADC Conversion Clock Source and Prescaler".
- E-2. Select the sample time using SAMC<4:0> (AD1CON3<12:8>), if auto-convert is to be used, as described in Section 22.3.12 "Acquisition Time Considerations".
- E-3. Select the ADC clock prescaler using ADCS<7:0> (AD1CON3<7:0>), as described in Section 22.3.11 "Selecting the ADC Conversion Clock Source and Prescaler".
- F. Turn on ADC module using AD1CON1<15>, as described in **Section 22.3.13 "Turning the ADC On"**.

Note: Steps A through E, above, can be performed in any order, but Step F must be the final step in every case.

- 2. To configure ADC interrupt (if required).
 - A-1. Clear AD1IF bit (IFS1<1>), as described in **Section 8.0 "Interrupts"**.
 - A-2. Select ADC interrupt priority AD1IP<2:0> (IPC<28:26>) and sub priority AD1IS<1:0> (IPC<24:24>), as described in **Section 8.0** "**Interrupts**", if interrupts are to be used.
- 3. Start the conversion sequence by initiating sampling, as described in Section 22.3.14 "Initiating Sampling".

22.3.1 CONFIGURING ANALOG PORT PINS

The AD1PCFG register and the TRISB register control the operation of the ADC port pins.

AD1PCFG specifies the configuration of device pins to be used as analog inputs. A pin is configured as an analog input when the corresponding PCFGn bit (AD1PCFG<n>) = 0. When the bit = 1, the pin is set to digital control. When configured for analog input, the associated port I/O digital input buffer is disabled so it does not consume current. The AD1PCFG register is cleared at Reset, causing the ADC input pins to be configured for analog input by default at Reset.

TRIS registers control the digital function of the port pins. The port pins that are desired as analog inputs must have their corresponding TRIS bit set, specifying the pin as an input. If the I/O pin associated with an ADC input is configured as an output, the TRIS bit is cleared and the ports digital output level (VOH or VOL) will be converted. After a device Reset, all TRIS bits are set.

Notes: When reading a PORT register that shares pins with the ADC, any pin configured as an analog input reads as a '0' when the PORT latch is read.

Analog levels on any pin that is defined as a digital input (including the AN15:AN0 pins), but is not configured as an analog input, may cause the input buffer to consume current that is out of the device's specification.

22.3.2 SELECTING THE ANALOG INPUTS TO THE ADC MUXS

The AD1CHS register is used to select which analog input pin is connected to MUX A and MUX B. Each MUX has two inputs referred to as the positive and the negative input. The positive input to MUX A is controlled by CH0SA<4:0> and the negative input is controlled by CH0NA. The positive input for MUX B is controlled by CH0SB<4:0> and the negative input is controlled by CH0NB.

The positive input can be selected from any one of the available analog input pins. The negative input can be selected as the ADC negative reference or AN0. The use of AN0 as the negative input allows the ADC to be used in a Unipolar Differential mode. Refer to the device data sheet for AN0 input voltage restrictions when used as a negative reference.

22.3.3 SELECTING THE FORMAT OF THE ADC RESULT

The data in the ADC Result register can be read as one of eight formats. The format is controlled by FORM<2:0> (AD1CON1<10:8>). The user can select from integer, signed integer, fractional or signed fractional as a 16-bit or 32-bit result.

22.3.3.1 Selecting the Sample Clock Source

It is often desirable to synchronize the end of sampling and the start of conversion with some other time event. The ADC module may use one of four sources as a conversion trigger. The selection of the conversion trigger source is controlled by the SSRC<2:0> (AD1CON1<7:5>) bits.

22.3.3.2 Manual Conversion

To configure the ADC to end sampling and start a conversion when SAMP is cleared (= 0), SSRC is set to '000'.

22.3.3.3 Timer Compare Trigger

The ADC is configured for this Trigger mode by setting SSRC<2:0> = 010. When a period match occurs for the 32-bit timer, TMR3/TMR2, or the 16-bit Timer3, a special A/D converter trigger event signal is generated by Timer3.

22.3.3.3.1 External INT0 Pin Trigger

To configure the ADC to begin a conversion on an active transition on the INT0 pin, SSRC<2:0> is set to '001'. The INT0 pin may be programmed for either a rising edge input or a falling edge input to trigger the conversion process.

22.3.3.3.2 Auto-Convert

The ADC can be configured to automatically perform conversions at the rate selected by the Auto-Sample Time bits, SAMC<4:0>. The ADC is configured for this Trigger mode by setting SSRC<2:0> = 111. In this mode, the ADC will perform continuous conversions on the selected channels.

22.3.4 SYNCHRONIZING ADC OPERATIONS TO INTERNAL OR EXTERNAL EVENTS

The modes where an external event trigger pulse ends sampling and starts conversion (SSRC2:SSRC0 = 001, 010 or 011) may be used in combination with auto-sampling (ASAM = 1) to cause the ADC to synchronize the sample conversion events to the trigger pulse source. For example, where SSRC = 010 and ASAM = 1, the ADC will always end sampling and start conversions synchronously with the timer compare trigger event. The ADC will have a sample conversion rate that corresponds to the timer comparison event rate.

22.3.5 SELECTING AUTOMATIC OR MANUAL SAMPLING

Sampling can be started manually or automatically when the previous conversion is complete.

22.3.5.1 Manual

Clearing the ASAM (AD1CON1<2>) bit disables the Auto-Sample mode. Acquisition will begin when the SAMP (AD1CON1<1>) bit is set by software. Acquisition will not resume until the SAMP bit is once again set.

22.3.5.2 Automatic

Setting the ASAM (AD1CON1<2>) bit enables the Auto-Sample mode. In this mode, the sampling will start automatically after the pervious sample has been converted.

22.3.6 SELECTING THE VOLTAGE REFERENCE SOURCE

The user can select the voltage reference for the ADC module. The reference can be internal or external.

The VCFG<2:0> control bits (AD1CON2<15:13>) select the voltage reference for A/D conversions. The upper voltage reference (VR+) and the lower voltage reference (VR-) may be the internal AVDD and AVSS voltage rails, or the VREF+ and VREF- input pins. 22.3.7 SELECTING THE SCAN MODE

The ADC module has the ability to scan through a selected vector of inputs. The CSCNA bit (AD1CON2<10>) enables the MUX A input to be scanned across a selected number of analog inputs.

22.3.7.1 Scan Mode Enable

Scan mode is enabled by setting CSCNA (AD1CON2<10>). When Scan mode is enabled, the positive input of MUX A is controlled by the contents of the AD1CSSL register. Each bit in the AD1CSSL register corresponds to an analog input. Bit 0 corresponds to AN0, bit 1 corresponds to AN1 and so on. If a particular bit in the AD1CSSL register is '1', the corresponding input is part of the scan sequence.

22.3.7.2 Using Scan and Alternate Modes Together

The Scan and Alternate modes may be combined to allow a vector of inputs to be scanned and a single input to be converted every other sample.

This mode is enabled by setting the CSCNA bit = 1, and setting the ALTS (AD1CON2<0>) bit = 1.

The CSCNA bit enables the scan for MUX A, and the CH0SB<3:0> (AD1CHS<27:24>) and CH0NB (AD1CHS<31>) are used to configure the inputs to MUX B. Scanning only applies to the MUX A input selection. The MUX B input selection, as specified by CH0SB<3:0>, will still select a single input.

22.3.8 SETTING THE NUMBER OF CONVERSIONS PER INTERRUPT

The SMPI<3:0> bits (AD1CON2<5:2>) select how many A/D conversions will take place before a CPU interrupt is generated. This also defines the number of locations that will be written in the result buffer stating with ADC1BUF0 (ADC1BUF0 or ADC1BUF8 for Dual Buffer mode). This can vary from 1 sample to 16 samples (1 to 8 samples for Dual Buffer mode). After the interrupt is generated, the sampling sequence restarts; with the result of the first sample being written to the first buffer location.

The data in the result registers will be overwritten by the next sampling sequence. The data in the result buffer must be read before the completion of the first sample after the interrupt is generated.

22.3.9 BUFFER FILL MODE

The Buffer Fill mode allows the output buffer to be used as a single, 16-word buffer or two, 8-word buffers.

When BUFM is '0', the complete 16-word buffer is used for all conversion sequences. Conversion results will be written sequentially in the buffer, starting at ADC1BUF0 until the number of samples as defined by SMPI<3:0> (AD1CON2<5:2>) is reached. The next conversion result will be written to ADC1BUF0 and the process repeats. If the ADC interrupt is enabled, an interrupt will be generated when the number of samples in the buffer equals SMPI<3:0>.

When the BUFM bit (AD1CON2<1>) is '1', the 16-word results buffer (ADRES) will be split into two 8-word groups. Conversion results will be written sequentially into the first buffer starting at ADC1BUF0, BUFS (AD1CON2<7>) will be cleared, until the number of samples as defined by SMPI<3:0> (AD1CON2<5:2>) is reached. The ADC interrupt flag will then be set.

After the ADC interrupt flag is set, the following result will be written sequentially to the second buffer, starting at ADC1BUF8 The next conversion result will be written to the second buffer; starting at ADC1BUF8, BUFS (AD1CON2<7>) will be set until the number of samples as defined by SMPI<3:0> (AD1CON2<5:2>) is reached. The ADC interrupt flag will then be set.

The process then restarts with BUFS = 0 and the results being written to the first buffer.

22.3.10 SELECTING THE MUX TO BE CONNECTED TO THE ADC (ALTERNATING SAMPLE MODE)

The ADC has two input MUXs that connect to the SHA. These MUXs are used to select which analog input is to be sampled. Each of the MUXs have a positive and a negative input.

22.3.10.1 Single Input Selection

The user may select one of up to 16 analog inputs, as determined by the number of analog channels on the device, as the positive input of the SHA. The CH0SA<3:0> bits (AD1CHS<19:16>) select the positive analog input.

The user may select either VR- or AN1 as the negative input. The CH0NA bit (AD1CHS<23>) selects the analog input for the negative input of channel 0. Using AN1 as the negative input allows unipolar differential measurements.

The ALTS bit (AD1CON2<0>) must be clear for this mode of operation.

22.3.10.2 Alternating Input Selections

The ALTS bit causes the module to alternate between the two input MUXs.

The inputs specified by CH0SA<3:0> and CH0NA are called the MUX A inputs. The inputs specified by CH0SB<3:0> and CH0NB are called the MUX B inputs.

When ALTS is '1', the module will alternate between the MUX A inputs on one sample and the MUX B inputs on the subsequent sample. When ALTS is '0', only the inputs specified by CH0SA<3:0> and CH0NA are selected for sampling.

22.3.11 SELECTING THE ADC CONVERSION CLOCK SOURCE AND PRESCALER

The ADC module can use the internal RC oscillator or the PBCLK as the conversion clock source.

When the internal RC oscillator is used as the clock source, ADRC (AD1CON3<15>) = 1, the TAD is the period of the oscillator, no prescaler are used. When using the internal oscillator the ADC can continue to function in SLEEP and in IDLE.

When the PBCLK is used as the conversion clock source, ADRC = 0, the TAD is the period of the PBCLK after the prescaler ADCS < 7:0 > (AD1CON3 < 7:0 >) is applied.

The A/D converter has a maximum rate at which conversions may be completed. An analog module clock, TAD, controls the conversion timing. The A/D conversion requires 12 clock periods (12 TAD).

The period of the ADC conversion clock is software selected using a 8-bit counter. There are 256 possible options for TAD, specified by the ADCS<7:0> bits (AD1CON3<7:0>).

Equation 22-3 gives the TAD value as a function of the ADCS control bits and the device instruction cycle clock period, TCY.

EQUATION 22-3: ADC CONVERSION CLOCK PERIOD

 $TAD = 2 \cdot (TPB(AADCS + 1))$

ADCS = $(TAD/(2 \bullet TPB)) - 1$

For correct A/D conversions, the ADC conversion clock (TAD) must be selected to meet the minimum TAD time.

EQUATION 22-4: AVAILABLE SAMPLING TIME, SEQUENTIAL SAMPLING

TSMP	=	Trigger Pulse Interval (TSEQ) – Conversion Time (TCONV)
TSMP	=	Tseq – Tconv

Note: TSEQ is the trigger pulse interval time.

22.3.12 ACQUISITION TIME CONSIDERATIONS

Different acquisition/conversion sequences provide different times for the sample-and-hold channel to acquire the analog signal. The user must ensure the acquisition time meets the sampling requirements.

When SSRC<2:0> (AD1CON1<7:5>) = 111, the conversion trigger is under ADC clock control. The SAMC<4:0> bits (AD1CON3<12:8>) select the number of TAD clock cycles between the start of acquisition and the start of conversion. This trigger option provides the fastest conversion rates on multiple channels. After the start of acquisition, the module will count a number of TAD clocks specified by the SAMC bits.

22.3.13 TURNING THE ADC ON

When the ON bit (AD1CON1<15>) is '1', the module is in Active mode and is fully powered and functional.

When ON is '0', the module is disabled. The digital and analog portions of the circuit are turned off for maximum current savings.

In order to return to the Active mode from the Off mode, the user must wait for the analog stages to stabilize. For the stabilization time, refer to the Electrical Characteristics section of the device data sheet.

Note:	Writing to ADC control bits other than
	ON (AD1CON1<15>), SAMP
	(AD1CON1<1>), and DONE
	(AD1CON1<0>) is not recommended
	while the A/D converter is running.

22.3.14 INITIATING SAMPLING

22.3.14.1 Manual Mode

In manual sampling, a acquisition is started by writing a '1' to the SAMP (AD1CON1<1>) bit. Software must manually manage the start and end of the acquisition period by setting SAMP and then clearing SAMP after the desired acquisition period has elapsed.

22.3.14.2 Auto-Sample Mode

In Auto-Sample mode, the sampling process is started by writing a '1' to the ASAM (AD1CON1<2>) bit. In Auto-Sample mode, the acquisition period is defined by ADCS<7:0> (AD1CON3<7:0>). Acquisition is automatically started after a conversion is completed. Auto-Sample mode can be used with any trigger source other than manual.

22.3.15 500 KSPS CONFIGURATION GUIDELINE

The configuration for 500 ksps operation is dependent on whether a single input pin or multiple pins will be sampled.

22.3.15.1 500 ksps Configuration Procedure

The following configuration items are required to achieve a 500 ksps conversion rate.

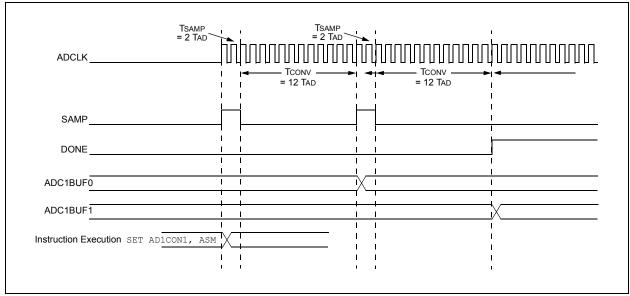

- Connect external VREF+ and VREF- pins following the recommended circuit shown in Figure 22-3.
- Set SSRC<2:0> = 111 in the AD1CON1 register to enable the auto convert option.
- Enable automatic sampling by setting the ASAM control bit in the AD1CON1 register.
- Configure the ADC clock period to be:

$\frac{1}{12 \times 1,\,000,\,000} = 83.33\,ns$

by writing to the ADCS<5:0> control bits in the AD1CON3 register.

• Configure the sampling time to be 2 TAD by writing: SAMC<4:0> = 00010.

FIGURE 22-3: CONVERTING 1 CHANNEL AT 400 KSPS, AUTO-SAMPLE START, 2 TAD SAMPLING TIME

22.4 Miscellaneous ADC Functions

The following section describes bits not covered in the previous section.

22.4.1 Aborting Sampling

Clearing the SAMP (AD1CON1<1>) bit while in Manual Sample mode will terminate sampling, but may also start a conversion if SSRC (AD1CON1<7:5>) = 000.

Clearing the ASAM (AD1CON1<2>) bit while in Auto-Sample mode will not terminate an ongoing acquire/convert sequence, however, sampling will not automatically resume after the current sample is converted.

22.4.2 ABORTING A CONVERSION

Clearing the ON (AD1CON1<15>) bit during a conversion will abort the current conversion. The ADC Result register will NOT be updated with the partially completed A/D conversion sample. That is, the corresponding result buffer location will continue to contain the value of the last completed conversion (or the last value written to the buffer).

22.4.3 BUFFER FILL STATUS

When the conversion result buffer is split using the BUFM control bit, the BUFS Status bit (AD1CON2<7>) indicates which half of the buffer the A/D converter is currently filling. If BUFS = 0, then the A/D converter is filling ADC1BUF0-ADC1BUF7 and the user software should read conversion values from ADC1BUF8-ADC1BUFF. If BUFS = 1, the situation is reversed and the user software should read conversion values from ADC1BUF0-ADC1BUF7.

22.4.4 OFFSET CALIBRATION

The ADC module provides a method of measuring the internal offset error. After this offset error is measured, it can be subtracted, in software, from the result of an A/D conversion. Use the following steps to perform an offset measurement:

- 1. Configure the A/D converter in the same manner as it will be used in the application.
- Set the OFFCAL bit (AD1CON2<12>). This overrides the input selections and connects the sample and hold inputs to AVss.
- 3. If auto-sample is used set the CLRASAM bit (AD1CON1<4>) to force conversions.
- 4. Enable the A/D converter and perform a conversion. The result that is written to the ADC result buffer is the internal offset error.
- 5. Clear the OFFCAL (AD2CON<12>) bit to return the A/D converter to normal operation.

Note:	Only	positive	ADC	offsets	can	be
	meas	ured with	this me	ethod.		

22.4.5 TERMINATE CONVERSION SEQUENCE AFTER AN INTERRUPT

The CLRASAM bit provides a method to terminate auto-sample after the first sequence is completed. Setting the CLRASAM and starting an auto-sample sequence will cause the A/D converter to complete one auto-sample sequence (the number of samples as defined by SMPI<3:0> (AD1CON2<5:2>)). Hardware will clear ASAM (AD1CON1<2>) and set the interrupt flag. This will stop the sampling process to allow inspection of the result buffer without results being overwritten by the next automatic conversion sequence. The CLRASAM must be cleared by software to disable this mode.

Note: Disabling interrupts or masking the ADC interrupt has no effect on the operation of the CLRASAM bit.

22.4.6 CONVERSION SEQUENCE EXAMPLES

The following configuration examples show the ADC operation in different sampling and buffering configurations. In each example, setting the ASAM bit starts automatic sampling. A conversion trigger ends sampling and starts conversion.

22.4.7 MANUAL CONVERSION CONTROL

When SSRC<2:0> = 000, the conversion trigger is under software control. Clearing the SAMP bit (AD1CON1<1>) starts the conversion sequence. See Example 22-1 for sample code to manually control the sampling of a single channel.

EXAMPLE 22-1: CONVERTING 1 CHANNEL, MANUAL SAMPLE START, MANUAL CONVERSION START CODE

```
// PORTB = Digital; RB2 = analog
AD1PCFG = 0xFFFB;
AD1CON1 = 0 \times 0000;
                               // SAMP bit = 0 ends sampling ...
                               // and starts converting
AD1CHS = 0 \times 00020000;
                              // Connect RB2/AN2 as CH0 input ..
                               // in this example RB2/AN2 is the input
AD1CSSL = 0;
AD1CON3 = 0 \times 0002;
                               // Manual Sample, Tad = 6 TPB
AD1CON2 = 0;
                              // turn ADC ON
AD1CON1SET = 0 \times 8000;
while (1)
                               // repeat continuously
{
                            // start sampling ...
  AD1CON1SET = 0x0002;
  DelayNmSec(100); // for 100 mS
AD1CON1CLR = 0x0002; // start Conve
                              // start Converting
  while (!(AD1CON1 & 0x0001));// conversion done?
  ADCValue = ADC1BUF0;
                               // yes then get ADC value
                                // repeat
```

22.4.8 AUTOMATIC ACQUISITION

Automatic acquisition control is enabled by setting the ASAM (AD1CON1<2>) bit. Setting the ASAM bit initiates automatic acquisition, and clearing the SAMP (AD1CON1<1>) bit terminates sampling and starts conversion. After the conversion completes, the module will automatically return to an acquisition state. The SAMP bit is automatically set at the start of the acquisition interval. The user software must time the clearing of the SAMP bit to ensure adequate acquisition time of the input signal, understanding that the time between clearing of the SAMP bit includes the conversion time as well as the acquisition time. See Example 22-2 for a code example.

EXAMPLE 22-2: CONVERTING 1 CHANNEL, AUTOMATIC SAMPLE START, MANUAL CONVERSION START CODE

```
// all PORTB = Digital but RB7 = analog
AD1PCFG = 0xFF7F;
AD1CON1 = 0 \times 0004;
                             // ASAM bit = 1 implies acquisition ..
                             // starts immediately after last
                             // conversion is done
AD1CHS = 0 \times 00070000;
                            // Connect RB7/AN7 as CH0 input ..
                             // in this example RB7/AN7 is the input
AD1CSSL = 0;
AD1CON3 = 0 \times 0002;
                             // Sample time manual, Tad = 6 TPB
AD1CON2 = 0;
AD1CON1SET = 0x8000;
                            // turn ADC ON
while (1)
                             // repeat continuously
 DelayNmSec(100);
                           // sample for 100 mS
 AD1CON1SET = 0x0002;
                            // start Converting
 while (!(AD1CON1 & 0x0001));// conversion done?
 ADCValue = ADC1BUF0;
                         // yes then get ADC value
}
                             // repeat
```

22.4.9 CLOCKED CONVERSION TRIGGER

When SSRC<2:0> = 111, the conversion trigger is under ADC clock control. The SAMC bits (AD1CON3<4:0>) select the number of T_{AD} clock cycles between the start of acquisition and the start of conversion. This trigger option provides the fastest conversion rates on multiple channels. After the start of acquisition, the module will count a number of T_{AD} clocks specified by the SAMC bits.

EQUATION 22-1: CLOCKED CONVERSION TRIGGER TIME

TSMP = SAMC < 4:0 > * TAD

SAMC must always be programmed for at least one clock cycle. See Example 22-1 for a code example.

Example 22-1: Converting 1 Channel, Manual Sample Start, TAD Based Conversion Start Code

```
AD1PCFG = 0xEFFF;
                                         // all PORTB = Digital; RB12 = analog
AD1CON1 = 0 \times 00E0;
                                         // SSRC bit = 111 implies internal
                                         // counter ends sampling and starts
                                         // converting.
AD1CHS = 0 \times 0000C0000;
                                         // Connect RB12/AN12 as CHO input ..
                                         // in this example RB12/AN12 is the input
AD1CSSL = 0;
AD1CON3 = 0 \times 1F02;
                                         // Sample time = 31Tad
AD1CON2 = 0;
AD1CON1SET = 0 \times 8000;
                                         // turn ADC ON
                                         // repeat continuously
while (1)
{
                                         // start sampling then \ldots
  AD1CON1CLR = 0 \times 0002;
                                         // after 31Tad go to conversion
  while (!(AD1CON1 & 0x0001));
                                         // conversion done?
                                         //\ensuremath{\,\mathrm{yes}} then get ADC value
  ADCValue = ADC1BUF0;
                                         // repeat
}
```

```

```

22.4.10 Free-Running Sample Conversion Sequence

The Auto-Convert Conversion Trigger mode (SSRC = 111) in combination with the Automatic Sampling Start mode (ASAM = 1), allows the ADC module to schedule acquisition/conversion sequences with no intervention by the user or other device resources. This "Clocked" mode allows continuous data collection after module initialization. See Example 22-3 for a code example.

EXAMPLE 22-3: CONVERTING 1 CHANNEL, AUTO-SAMPLE START, AUTO-CONVERT CODE

```
AD1PCFG = 0xFFFB;
                                        // all PORTB = Digital; RB2 = analog
AD1CON1 = 0 \times 00E0;
                                        // SSRC bit = 111 internal
                                        // counter ends sampling and starts
                                        // converting.
AD1CHS = 0 \times 00020000;
                                        // Connect RB2/AN2 as CH0 input ..
                                        // in this example RB2/AN2 is the input
AD1CSSL = 0;
AD1CON3 = 0 \times 0 F00;
                                        // Sample time = 15Tad
AD1CON2 = 0 \times 0004;
                                        // Interrupt after every 2 samples
AD1CON1SET = 0 \times 8000;
                                        // turn ADC ON
AD1CON1SET = 0 \times 0004;
                                        // auto start sampling
                                        // repeat continuously
while (1)
                                        // clear ADC interrupt flag
{ IFS1CLR = 0 \times 0002;
                                            // for 31Tad then go to conversion
  while (!IFS1 & 0x0002);
                                        // poll for conversion done \
                                        // result of conversions is available in ADC1BUF0
                                        // and ADC1BUF1
```

22.4.11 SAMPLING A SINGLE CHANNEL MULTIPLE TIMES

In this case, one ADC input, AN0, will be acquired and converted. The results are stored in the ADC1BUF buffer. This process repeats 15 times until the buffer is full, and then the module generates an interrupt. Then entire process repeats.

With ALTS (AD1CON2<0>) clear, only the MUX A inputs are active. The CH0SA (AD1CHS<19:16>) bits and CH0NA (AD1CHS<23>) bit are specified (AN0-VREF-) as the input to the sample/hold channel. Other input selection bits are not used.

22.4.12 EXAMPLE: A/D CONVERSIONS WHILE SCANNING THROUGH ANALOG INPUTS

A typical setup might include all available analog input channels to be sampled and converted. The CSCNA (AD1CON2<10>) bit specifies scanning of the ADC inputs. Other conditions are similar to the previous example (see Section 22.4.11 "Sampling a Single Channel Multiple Times").

Initially, the AN0 input is acquired and converted. The result is stored in the ADC1BUF buffer. Then the AN1 input is acquired and converted. This process of scanning the inputs repeats 16 times until the buffer is full and then the module generates an interrupt. Then the entire process repeats.

22.4.12.1 Example: Using Dual 8-Word Buffers

To enable the dual 8-word buffers and alternating the buffer fill, set the BUFM (AD1CON2<1>) bit. The BUFM setting does not affect other operational parameters. First, the conversion sequence starts filling the buffer at ADC1BUF0 (buffer location 0×0). After the first interrupt occurs, the buffer begins to fill at ADC1BUF8 (buffer location 0×8). The BUFS (AD1CON2<7>) bit is alternately set and cleared after each interrupt to show which buffer is being filled. In this example, three analog inputs are sampled and an interrupt occurs after every third sample.

22.4.12.2 Example: Using Alternating MUX A, MUX B Input Selections

Setting the ALTS (AD1CON2<0>) bit enables alternating input selections. The first sample uses the MUX A inputs specified by the CH0SA (AD1CHS<19:16>) and CH0NA (AD1CHS<23>) bits. The next sample uses the MUX B inputs specified by the CH0SB (AD1CHS<27:24>) and CH0NB (AD1CHS<31>) bits.

In the following example, one of the MUX B input specifications uses 2 analog inputs as a differential source to the sample/hold.

This example also demonstrates use of the dual 8-word buffers. An interrupt occurs after every 4th sample, which results in filling 4-words into the buffer on each interrupt.

22.4.12.3 Example: Converting Three Analog Inputs Using Alternating Sample Mode and a Scan List

It is possible to sample by scanning through the input channels and alternate between MUX A and MUX B. When the Alternating Sample mode is selected, the first input to be sampled will be the input selected for MUX A, the second sample will be the input selected for MUX B. Then the process repeats. When scanning is combined with Alternating Input mode, the positive input to MUX A is selected by the contents of the AD1CSSL register, not CH0SA. For each sample that MUX A is selected the next item in the scan list is sampled. The positive input to MUX B is selected by CH0SB (AD1CHS<27:24>).

When ASAM (AD1CON1<2>) is clear, sampling will not resume after conversion completion, but will occur when setting the SAMP (AD1CON1<1>) bit.

22.5 Initialization

A simple initialization code example for the ADC module is provided in Example 22-4.

In this particular configuration, all 16 analog input pins, AN0-AN15, are set up as analog inputs. Operation in IDLE mode is disabled, output data is in unsigned fractional format, and AVDD and AVSs are used for VR+ and VR-. The start of acquisition, as well as start of conversion (conversion trigger), are performed manually in software. The CH0 SHA is used for conversions. Scanning of inputs is disabled, and an interrupt occurs after every acquisition/convert sequence (1 conversion result). The ADC conversion clock is TPB/2.

Since acquisition is started manually by setting the SAMP bit (AD1CON1<1>) after each conversion is complete, the auto-sample time bits, SAMC<4:0> (AD1CON3<12:8>), are ignored. Moreover, since the start of conversion (i.e., end of acquisition) is also triggered manually, the SAMP bit needs to be cleared each time a new sample needs to be converted.

EXAMPLE 22-4: ADC INITIALIZATION CODE EXAMPLE

AD1PCFG = 0x0000;	/* Configure ADC port all input pins are analog */
AD1CON1 = 0x2208;	<pre>/* Configure sample clock source and Conversion Trigger mode. Unsigned Fractional format, Manual conversion trigger, Manual start of sampling, Simultaneous sampling, No operation in IDLE mode. */</pre>
AD1CON2 = 0x0000;	<pre>/* Configure ADC voltage reference and buffer fill modes. VREF from AVDD and AVSS, Inputs are not scanned, Interrupt every sample */</pre>
AD1CON3 = 0×0000 ;	/* Configure ADC conversion clock */
AD1CHS = 0x0000;	/* Configure input channels, CH0+ input is ANO. CHO- input is VREFL (AVss)
AD1CSSL = 0x0000;	<pre>/* No inputs are scanned. Note: Contents of AD1CSSL are ignored when CSCNA = 0 */</pre>
IFS1CLR = 2;	/*Clear ADC conversion interrupt*/
<pre>// Configure ADC interrupt pr // required. (default priorit</pre>	riority bits (AD1IP<2:0>) here, if ry level is 4)
IEC1SET = 2;	/* Enable ADC conversion interrupt*/
	<pre>/* Turn on the ADC module */ /* Start sampling the input */ /* Ensure the correct sampling time has elapsed before starting a conversion.*/</pre>
AD1CON1CLR = 0x0002; :	<pre>/* End Sampling and start Conversion*/ /* The DONE bit is set by hardware when the convert sequence is finished. */ /* The ADIF bit will be set. */</pre>
•	, the libit bit will be bee. /

22.6 I/O Pin Control

The pins used for analog input can also be used for digital I/O. Configuring a pin for analog input requires three steps. Any digital peripherals that share the desired pin must be disabled. The pin must be configured as a digital input, by setting the corresponding TRIS bit to a '1' to disable the output driver. Then, the pin must be placed in Analog mode by setting the corresponding bit in the AD1PCFG register.

Pin Name	Module Control	Controlling Bit Field		Buffer Type	TRIS	Description
AN0	ON	AD1PCFG<0>	Α	_	Input	Analog Input
AN1	ON	AD1PCFG<1>	Α	_	Input	Analog Input
AN2	ON	AD1PCFG<2>	Α	_	Input	Analog Input
AN3	ON	AD1PCFG<3>	Α	_	Input	Analog Input
AN4	ON	AD1PCFG<4>	Α	_	Input	Analog Input
AN5	ON	AD1PCFG<5>	Α	_	Input	Analog Input
AN6	ON	AD1PCFG<6>	Α	_	Input	Analog Input
AN7	ON	AD1PCFG<7>	Α	_	Input	Analog Input
AN8	ON	AD1PCFG<8>	Α	_	Input	Analog Input
AN9	ON	AD1PCFG<9>	Α	_	Input	Analog Input
AN10	ON	AD1PCFG<10>	Α	_	Input	Analog Input
AN11	ON	AD1PCFG<11>	Α	_	Input	Analog Input
AN12	ON	AD1PCFG<12>	Α	—	Input	Analog Input
AN13	ON	AD1PCFG<13>	Α	_	Input	Analog Input
AN14	ON	AD1PCFG<14>	Α	_	Input	Analog Input
AN15	ON	AD1PCFG<15>	Α	—	Input	Analog Input
VREF+	ON	AD1CON2<15:13>	Р	_	—	Positive Voltage Reference
VREF-	ON	AD1CON2<15:13>	Р	_	—	Negative Voltage Reference

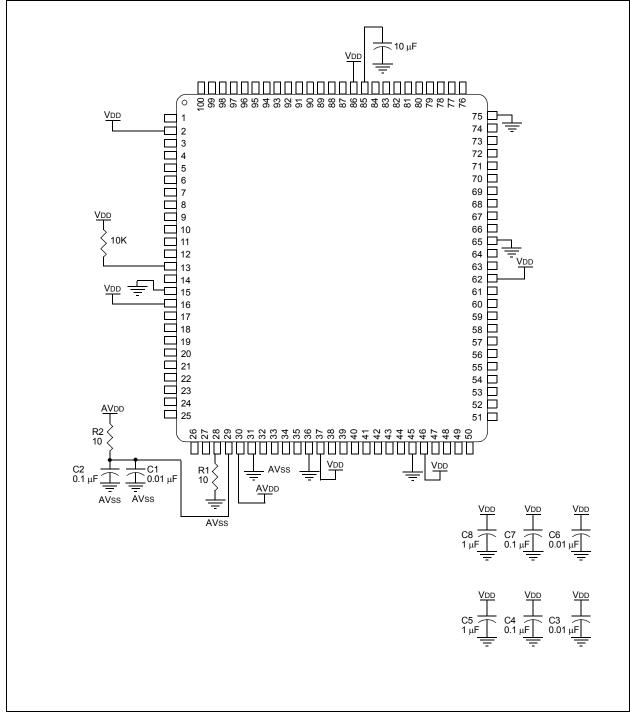

TABLE 22-2:	PINS ASSOCIATED WITH THE ADC MODULE

Legend: ST = Schmitt Trigger input with CMOS levels I = Input

O = Output

A = Analog P = Power

22.6.1 ADC CONVERSION SPEEDS

The PIC32MX 10-bit A/D converter specifications permit a maximum 500 ksps sampling rate. Table 22-3 summarizes the conversion speeds for the PIC32MX 10-bit A/D converter and the required operating conditions.

TABLE 22-3: 10-BIT CONVERSION RATE PARAMETERS

		PIC32	MX 10-Bi	t A/D Converte	r Conversion Rat	es
ADC Speed	TAD Minimum	Sampling Time Min	Rs Max	Vdd	Temperature	ADC Channels Configuration
500 ksps ⁽¹⁾	100 ns	2 Tad	500Ω	3.0V to 3.6V	-40°C to +85°C	ANX CHX ADC
Up to 400 ksps	200 ns	1 Tad	5.0 kΩ	2.5V to 3.6V	-40°C to +125°C	ANX ADC ANX of ViteF-
Up to 300 ksps	256.41 ns	1 Tad	5.0 kΩ	2.5V to 3.6V	-40°C to +125°C	ANX ADC ANX OF VREF-

Note 1: External VREF- and VREF+ pins must be used for correct operation.

22.6.2 ADC SAMPLING REQUIREMENTS

The analog input model of the 10-bit A/D converter is shown in Figure 22-5. The total acquisition time for the A/D conversion is a function of the internal amplifier settling time and the holding capacitor charge time.

For the A/D converter to meet its specified accuracy, the charge holding capacitor (CHOLD) must be allowed to fully charge to the voltage level on the analog input pin. The analog output source impedance (Rs), the interconnect impedance (RIC) and the internal sampling switch (RSS) impedance combine to directly affect the time required to charge the CHOLD. The combined impedance of the analog sources must therefore be small enough to fully charge the holding capacitor within the chosen sample time. To minimize the effects of pin leakage currents on the accuracy of the A/D converter, the maximum recommended source impedance, Rs, is 5 k Ω for the conversion rates of up to 400 ksps and a maximum of 500 Ω for conversion rates of up to 500 ksps). After the analog input channel is selected (changed), this acquisition function must be completed prior to starting the conversion. The internal holding capacitor will be in a discharged state prior to each sample operation.

At least 1 TAD time period should be allowed between conversions for the acquisition time. For more details, see the device electrical specifications.

23.0 POWER SAVING

Note:	This data sheet summarizes the features of
	the PIC32MX3XX/4XX family of devices. It
	is not intended to be a comprehensive refer-
	ence source. Refer to the "PIC32MX Family
	Reference Manual" (DS61132) for a
	detailed description of this peripheral.

This section describes power saving for the PIC32MX3XX/4XX. The PIC32MX devices offer a total of nine methods and modes that are organized into two categories that allow the user to balance power consumption with device performance. In all of the methods and modes described in this section, power saving is controlled by software.

23.1 Power Saving with CPU Running

When the CPU is running, power consumption can be controlled by reducing the CPU clock frequency, lowering the PBCLK, and by individually disabling modules. These methods are grouped into the following categories:

- FRC RUN mode: the CPU is clocked from the FRC clock source with or without postscalers.
- LPRC RUN mode: the CPU is clocked from the LPRC clock source.
- SOSC RUN mode: the CPU is clocked from the SOSC clock source.
- Peripheral Bus Scaling mode: Peripherals are clocked at programmable fraction of the CPU clock (SYSCLK).

23.2 CPU Halted Methods

The device supports two power-saving modes, SLEEP and IDLE, both of which halt the clock to the CPU. These modes operate with all clock sources, as listed below:

• POSC IDLE Mode: the system clock is derived from the POSC. The system clock source continues to operate.

Peripherals continue to operate, but can optionally be individually disabled.

- FRC IDLE Mode: the system clock is derived from the FRC with or without postscalers.
 Peripherals continue to operate, but can optionally be individually disabled.
- SOSC IDLE Mode: the system clock is derived from the SOSC.

Peripherals continue to operate, but can optionally be individually disabled.

• LPRC IDLE Mode: the system clock is derived from the LPRC.

Peripherals continue to operate, but can optionally be individually disabled. This is the lowest power mode for the device with a clock running.

• SLEEP Mode: the CPU, the system clock source, and any peripherals that operate from the system clock source, are halted.

Some peripherals can operate in SLEEP using specific clock sources. This is the lowest power mode for the device.

23.3 Power-Saving Modes Control Registers

Power-Saving modes control consists of the following Special Function Registers (SFRs):

 OSCCON: Control Register for the Oscillators Module

OSCCONCLR, OSCCONSET, OSCCONINV: Atomic Bit Manipulation Write-only Registers for OSCCON

- WDTCON: Control Register for the Watchdog Timer Module WDTCONCLR, WDTCONSET, WDTCONINV: Atomic Bit Manipulation Write-only Registers for WDTCON
- RCON: Control Register for the Resets Module RCONCLR, RCONSET, RCONINV: Atomic Bit Manipulation Write-only Registers for RCON

The following table summarizes Power-Saving modes registers. Corresponding registers appear after the summary, followed by a detailed description of each register.

23.4 Power-Saving Operation

Note: In this data sheet, a distinction is made between a power mode as it is used in a specific module, and a power mode as it is used by the device, e.g., Sleep mode of the Comparator and SLEEP mode of the CPU. To indicate which type of power mode is intended, uppercase and lowercase letters (Sleep, Idle, Debug) signify a module power mode, and all uppercase letters (SLEEP, IDLE, DEBUG) signify a device power mode.

The purpose of all power saving is to reduce power consumption by reducing the device clock frequency. To achieve this, low-frequency clock sources can be selected. In addition, the peripherals and CPU can be halted or disabled to further reduce power consumption.

23.5 SLEEP Mode

SLEEP mode has the lowest power consumption of the device Power-Saving operating modes. The CPU and most peripherals are halted. Select peripherals can continue to operate in SLEEP mode and can be used to wake the device from SLEEP. See the individual peripheral module sections for descriptions of behavior in Sleep.

SLEEP mode includes the following characteristics:

- · The CPU is halted.
- The system clock source is typically shut down. See Section 23.5.1 "Oscillator Shutdown In Sleep Mode" for specific information.
- There can be a wake-up delay based on the oscillator selection (refer to Table 23-2).
- The Fail-Safe Clock Monitor (FSCM) does not operate during Sleep mode.
- The BOR circuit, if enabled, remains operative during SLEEP mode.
- The WDT, if enabled, is not automatically cleared prior to entering SLEEP mode.
- Some peripherals can continue to operate in SLEEP mode. These peripherals include I/O pins that detect a change in the input signal, WDT, ADC, UART, and peripherals that use an external clock input or the internal LPRC oscillator, e.g., RTCC and Timer 1.
- I/O pins continue to sink or source current in the same manner as they do when the device is not in SLEEP.
- The USB module can override the disabling of the POSC or FRC. Refer to the USB section for specific details.
- Some modules can be individually disabled by software prior to entering SLEEP in order to further reduce consumption.

The processor will exit, or 'wake-up', from SLEEP on one of the following events:

- On any interrupt from an enabled source that is operating in Sleep. The interrupt priority must be greater than the current CPU priority.
- · On any form of device Reset.
- On a WDT time-out. See Section 23.10 "Wakeup from SLEEP or IDLE on Watchdog Time-out (NMI)".

If the interrupt priority is lower than or equal to current priority, the CPU will remain halted, but the PBCLK will start running and the device will enter into IDLE mode.

Refer Example 23-1 for example code.

Note: There is no FRZ mode for this module.

23.5.1 OSCILLATOR SHUTDOWN IN SLEEP MODE

The criteria for the device disabling the clock source in SLEEP are: the oscillator type, peripherals using the clock source, and (for select sources) the clock enable bit.

- If the CPU clock source is POSC, it is turned off in SLEEP. See Table 23-2 for applicable delays when waking from SLEEP. The USB module can override the disabling of the POSC or FRC. Refer to the USB section for specific details.
- If the CPU clock source is FRC, it is turned off in SLEEP. See Table 23-2 for applicable delays when waking from SLEEP. The USB module can override the disabling of the POSC or FRC. Refer to the USB section for specific details.
- If the CPU clock source is SOSC, it will be turned off if the SOSCEN bit is not set. See Table 23-2 for applicable delays when waking from SLEEP.
- If the CPU clock source is LPRC, it will be turned off if the clock source is not being used by a peripheral that will be operating in SLEEP, such as the WDT. See Table 23-2 for applicable delays when waking from SLEEP.

23.5.2 CLOCK SELECTION ON WAKE-UP FROM SLEEP

The processor will resume code execution and use the same clock source that was active when SLEEP mode was entered. The device is subject to a start-up delay if a crystal oscillator and/or PLL is used as a clock source when the device exits SLEEP.

23.5.3 DELAY ON WAKE-UP FROM SLEEP

The oscillator start-up and Fail-Safe Clock Monitor delays (if enabled) associated with waking up from SLEEP mode are shown in Table 23-2.

Clock Source	Oscillator Delay	FSCM Delay
EC, EXTRC		—
EC + PLL	ТLОСК	TFSCM
XT + PLL	Tost + Tlock	TFSCM
XT, HS, XTL	Тоѕт	TFSCM
LP (OFF during Sleep)	Тоят	TFSCM
LP (ON during Sleep)	—	—
FRC, LPRC	_	_

Note:	
	tions" section of the PIC18F1220/1320
	device data sheet for TPOR, TFSCM and
	TLOCK specification values.

TABLE 23-2: DELAY TIMES FOR EXIT FROM SLEEP MODE

23.5.4 WAKE-UP FROM SLEEP MODE WITH CRYSTAL OSCILLATOR OR PLL

If the system clock source is derived from a crystal oscillator and/or the PLL, then the Oscillator Start-up Timer (OST) and/or PLL lock times will be applied before the system clock source is made available to the device. As an exception to this rule, no oscillator delays are applied if the system clock source is the POSC oscillator and it was running while in SLEEP mode.

Note: In spite of the various delays applied the crystal oscillator (and PLL) may not be up and running at the end of the TOST, or TLOCK delays. For proper operation the user must design the external oscillator circuit such that reliable oscillation will occur within the delay period.

23.5.5 FAIL-SAFE CLOCK MONITOR DELAY AND SLEEP MODE

The Fail-Safe Clock Monitor (FSCM) does not operate while the device is in SLEEP. If the FSCM is enabled it will resume operation when the device wakes from Sleep.

23.5.6 SLOW OSCILLATOR START-UP

When an oscillator starts slowly, the OST and PLL lock times may not have expired before FSCM times out.

If the FSCM is enabled, then the device will detect this condition as a clock failure and a clock event trap will occur. The device will switch to the FRC oscillator and the user can re-enable the crystal oscillator source in the clock failure Interrupt Service Routine.

If the FSCM is not enabled, then the device will simply not start executing code until the clock is stable. From the user's perspective, the device will appear to be in SLEEP until the oscillator clock has started.

23.5.6.1 The USB peripheral control of Oscillators in Sleep mode

For devices with a USB peripheral, POSC and FRC will remain active in Sleep if the USB module is not disabled prior to entering Sleep. The Oscillators remaining active will not stop the halting of the CPU or peripherals in Sleep.

EXAMPLE 23-1: PUT DEVICE IN SLEEP, THEN WAKE WITH WDT

```
// Code example to put the Device in sleep and then Wake the device
// with the WDT
OSCCONSET = 0 \times 10;
                       // set Power-Saving mode to Sleep
WDTCONCLR = 0 \times 0002;
                       // Disable WDT window mode
WDTCONSET = 0 \times 8000;
                       // Enable WDT
                       // WDT timeout period is set in the device configuration
while (1)
{
    ... user code ...
   WDTCONSET = 0x01; // service the WDT
    asm ( "wait" );
                      // put device in selected Power-Saving mode
                       // code execution will resume here after wake
    ... user code ...
}
// The following code fragment is at the beginning of the 'C' start-up code
if ( RCON & 0x18 )
{
                       // The WDT caused a wake from Sleep
    asm ( "eret" );
                       // return from interrupt
}
```

23.6 Peripheral Bus Scaling Method

Most of the peripherals on the device are clocked using the PBCLK. The peripheral bus can be scaled relative to the SYSCLK to minimize the dynamic power consumed by the peripherals. The PBCLK divisor is controlled by PBDIV<1:0> (OSCCON<20:19>), allowing SYSCLK-to-PBCLK ratios of 1:1, 1:2, 1:4, and 1:8. All peripherals using PBCLK are affected when the divisor is changed. Peripherals such as the Interrupt Controller, DMA, Bus Matrix, and Prefetch Cache are clocked directly from SYSCLK, as a result, they are not affected by PBCLK divisor changes.

Most of the peripherals on the device are clocked using the PBCLK. The peripheral bus can be scaled relative to the SYSCLK to minimize the dynamic power consumed by the peripherals. The PBCLK divisor is controlled by PBDIV<1:0> (OSCCON<20:19>), allowing SYSCLK-to-PBCLK ratios of 1:1, 1:2, 1:4, and 1:8. All peripherals using PBCLK are affected when the divisor is changed. Peripherals such as USB, Interrupt Controller, DMA, Bus Matrix, and Prefetch Cache are clocked directly from SYSCLK, as a result, they are not affected by PBCLK divisor changes

Changing the PBCLK divisor affects:

- The CPU to peripheral access latency. The CPU has to wait for next PBCLK edge for a read to complete. In 1:8 mode this results in a latency of one to seven SYSCLKs.
- The power consumption of the peripherals. Power consumption is directly proportional to the frequency at which the peripherals are clocked. The greater the divisor, the lower the power consumed by the peripherals.

To minimize dynamic power the PB divisor should be chosen to run the peripherals at the lowest frequency that provides acceptable system performance. When selecting a PBCLK divider, peripheral clock requirements such as baud rate accuracy should be taken into account. For example, the UART peripheral may not be able to achieve all baud rate values at some PBCLK divider depending on the SYSCLK value.

23.6.1 DYNAMIC PERIPHERAL BUS SCALING METHOD

The PBCLK can be scaled dynamically, by software, to save additional power when the device is in a low activity mode. The following issues need to be taken into account when scaling the PBCLK:

- All the peripherals clocked from PBCLK will scale at the same ratio, at the same time. This needs to be accounted in peripherals which need to maintain a constant baud rate, or pulse period even in low-power modes.
- Any communication through a peripheral on the peripheral bus that is in progress when the PBCLK changes may cause a data or protocol error due to a frequency change during transmission or reception.

The following steps are recommended if the user intends to scale the PBCLK divisor dynamically:

· Disable all communication peripherals whose

baud rate will be affected. Care should be taken to ensure that no communication is currently in progress before disabling the peripherals as it may result in protocol errors.

- Update the Baud Rate Generator (BRG) settings for peripherals as required for operation at the new PBCLK frequency.
- Change the peripheral bus ratio to the desired value.
- Enable all communication peripherals whose baud rate were affected.

Note: Modifying the peripheral baud rate is done by writing to the associated peripheral SFRs. To minimize latency, the peripherals should be modified in the mode where the PBCLK is running at its highest frequency.

EXAMPLE 23-2: CHANGING THE PB CLOCK DIVISOR

```
// Code example to change the PBCLK divisor
// This example is for a device running at 40 \rm MHz
// Make sure that there is no UART send/receive in progress
... user code ...
U1BRG = 0 \times 81;
                              // set baud rate for UART1 for 9600
... user code ...
OSCCONCLR = 0x3 << 19;
                          // set PB divisor to minimum (1:1)
... user code ...
// Change Peripheral Clock value
U1BRG = 0 \times 0F;
                               // set baud rate for UART1 for 9600 based on
                               // new PB clock frequency
OSCCONSET = 0x3 \ll 19;
                              // set PB divisor to maximum (1:8)
// Reset Peripheral Clock
OSCCONCLR = 0x3 \ll 19;
                               // set PB divisor to minimum (1:1)
U1BRG = 0 \times 81;
                               // restore baud rate for UART1 to 9600 based
                               // on new PB clock frequency
```

23.7 IDLE Modes

In the IDLE modes, the CPU is halted but the System clock (SYSCLK) source is still enabled. This allows peripherals to continue operation when the CPU is halted. Peripherals can be individually configured to halt when entering IDLE by setting their respective SIDL bit. Latency when exiting Idle mode is very low due to the CPU oscillator source remaining active.

Notes: Changing the PBCLK divider ratio requires recalculation of peripheral timing. For example, assume the UART is configured for 9600 baud with a PB clock ratio of 1:1 and a POSC of 8 MHz. When the PB clock divisor of 1:2 is used, the input frequency to the baud clock is cut in half; therefore, the baud rate is reduced to 1/2 its former value. Due to numeric truncation in calculations (such as the baud rate divisor), the actual baud rate may be a tiny percentage different than expected. For this reason, any timing calculation required for a peripheral should be performed with the new PB clock frequency instead of scaling the previous value based on a change in PB divisor ratio. Oscillator start-up and PLL lock delays are applied when switching to a clock source that was disabled and that uses a crystal and/or the PLL. For example, assume the clock source is switched from POSC to LPRC just prior to entering Sleep in order to save power. No oscillator start-up delay would be applied when exiting Idle. However, when switching back to POSC, the appropriate PLL and

or oscillator startup/lock delays would be

The device enters IDLE mode when the SLPEN (OSC-CON<4>) bit is clear and a WAIT instruction is executed.

The processor will wake or exit from IDLE mode on the following events:

- On any interrupt event for which the interrupt source is enabled. The priority of the interrupt event must be greater than the current priority of CPU. If the priority of the interrupt event is lower than or equal to current priority of CPU, the CPU will remain halted and the device will remain in IDLE mode.
- On any source of device Reset.
- On a WDT time-out interrupt. See Section 23.10 "Wake-up from SLEEP or IDLE on Watchdog Time-out (NMI)" and Section 26.0 "Watchdog Timer".

applied.

TABLE 23-3: PLACING DEVICE IN IDLE AND WAKING BY ADC EVENT

```
// Code example to put the Device in Idle and then Wake the device
// when the ADC completes a conversion
OSCCONCLR = 0x10; // set Power-Saving mode to Idle
asm ( "wait" ); // put device in selected Power-Saving mode
// code execution will resume here after wake and the ISR is complete
... user code ...
// interrupt handler
_____ADClInterrupt:
... ISR code ...
asm ( "eret" ); // return from interrupt
```

23.8 Interrupts

There are two sources of interrupts that will wake the device from a Power-Saving mode: peripheral interrupts, and a Non-Maskable Interrupt (NMI) generated by the WDT in Power-Saving mode.

23.9 Wake-Up from SLEEP or IDLE on Peripheral Interrupt

Any source of interrupt that is individually enabled using the corresponding IE control bit in the IECx register and is operational in the current Power-Saving mode will be able to wake-up the processor from SLEEP or IDLE mode. When the device wakes, one of two events will occur, based on the interrupt priority:

- If the assigned priority for the interrupt is less than, or equal to, the current CPU priority, the CPU will remain halted and the device enters, or remains in, IDLE mode.
- If the assigned priority level for the interrupt source is greater than the current CPU priority, the device will wake-up and the CPU will jump to the corresponding interrupt vector. Upon completion of the ISR, the CPU will start executing the next instruction after WAIT.

The IDLE Status bit (RCON<2>) is set upon wake-up from IDLE mode. The SLEEP Status bit (RCON<3>) is set upon wake-up from SLEEP mode.

Notes: A peripheral with an interrupt priority setting of zero cannot wake the device.

Any applicable oscillator start-up delays are applied before the CPU resumes code execution.

23.10 Wake-up from SLEEP or IDLE on Watchdog Time-out (NMI)

When the WDT times out in SLEEP or IDLE mode, an NMI is generated. The NMI causes the CPU code execution to jump to the device Reset vector. Although the CPU executes the Reset vector, it is not a device Reset, peripherals and most CPU registers do not change their states.

Note: Any applicable oscillator start-up delays are applied before the CPU resumes code execution.

To detect a wake from a Power-Saving mode caused by WDT expiration, the WDTO (RCON<4>), SLEEP (RCON<3>), and IDLE (RCON<2>) bits must be tested. If the WDTO bit is '1' the event was due to a WDT time-out. The SLEEP and IDLE bits can then be tested to determine if the WDT event occurred in Sleep or Idle.

To use a WDT time-out during SLEEP mode as a wakeup interrupt, a return from interrupt (ERET) instruction must be used in the start-up code after the event was determined to be a WDT wake-up. This will cause code execution to continue from the instruction following the WAIT instruction that put the device in Power-Saving mode.

Note:	If a peripheral interrupt and WDT event
	occur simultaneously, or in close proxim-
	ity, the NMI may not occur, due to the
	device being awakened by the peripheral
	interrupt. To avoid unexpected WDT
	Reset in this scenario, the WDT is auto-
	matically cleared when the device
	awakens.

See **Section 26.0 "Watchdog Timer"** for detailed information on the WDT operation.

23.11 Interrupts Coincident with Power-Saving Instruction

Any peripheral interrupt that coincides with the execution of a WAIT instruction will be held off until entry into SLEEP or IDLE mode has completed. The device will then wake-up from SLEEP or IDLE mode.

23.12 I/O Pins Associated with Power-Saving Modes

No device pins are associated with Power-Saving modes.

NOTES:

24.0 COMPARATOR

Note: This data sheet summarizes the features of the PIC32MX3XX/4XX family of devices. It is not intended to be a comprehensive reference source. Refer to the *"PIC32MX Family Reference Manual"* (DS61132) for a detailed description of this peripheral.

The PIC32MX3XX/4XX Analog Comparator module contains one or more comparator(s) that can be configured in a variety of ways.

Following are some of the key features of this module:

- Selectable inputs available include:
 - Analog inputs multiplexed with I/O pins
 - On-chip internal absolute voltage reference (IVREF)
 - Comparator voltage reference (CVREF)
- · Outputs can be inverted
- · Selectable interrupt generation

A block diagram of the comparator module is shown in Figure 24-1.

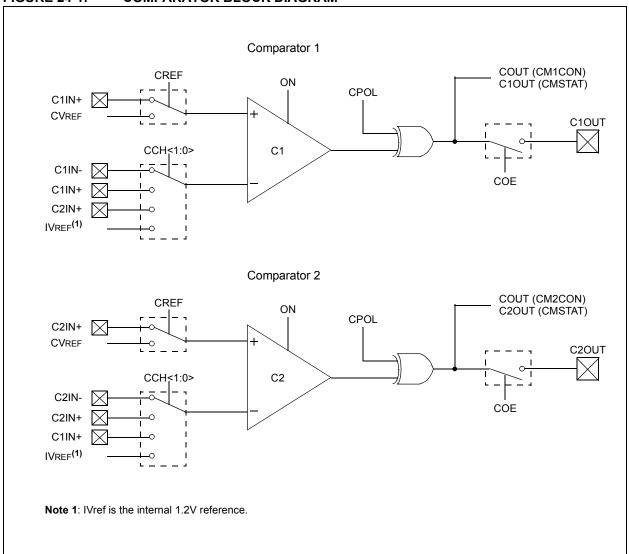

FIGURE 24-1: COMPARATOR BLOCK DIAGRAM

24.1 Comparator Control Registers

Note:	Each PIC32MX3XX/4XX device variant
	may have one or more Comparator mod-
	ules. An 'x' used in the names of pins,
	control/status bits and registers denotes
	the particular module. Refer to the specific
	device data sheets for more details.

A Comparator module consists of the following Special Function Registers (SFRs):

- CMxCON: Comparator Control Register
- CMxCONCLR, CMxCONSET, CMxCONINV: Atomic Bit Manipulation Registers for CMxCON
- · CMSTAT: Comparator Status Registers
- CMSTATCLR, CMSTATSET, CMSTATINV: Atomic Bit Manipulation Registers for CMSTAT

The comparator module also has the following interrupt control registers:

- IFS1: Interrupt Flag Status Register
- · IEC: Interrupt Enable Control Register
- IPC7: Interrupt Priority Control Register

24.2 Comparator Operation

24.2.1 COMPARATOR CONFIGURATION

The Comparator module has a flexible input and output configuration to allow the module to be tailored to the needs of the application. The PIC32MX3XX/4XX comparator module has individual control over the enables, output inversion, output on I/O pin and input selections. The VIN+ pin of each comparator can select from an input pin or the CVREF. The VIN- input of the comparator can select from one of 3 input pins or the IVREF. In addition, the module has two individual comparator event generation control bits. These control bits can be used for detecting when the output of an individual comparator changes to a desired state or changes states.

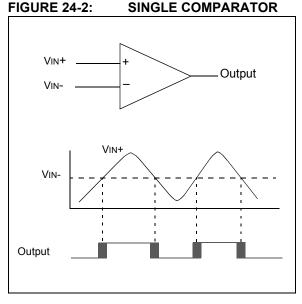

If the Comparator mode is changed, the comparator output level may not be valid for the specified mode change delay (refer to the device data sheet for more information).

Note:	Comparator interrupts should be disabled							
	during a Comparator mode change;							
	otherwise, a false interrupt may be gener-							
	ated.							

A single comparator is shown in the upper portion of Figure 24-2. The lower portion represents the relationship between the analog input levels and the digital output. When the analog input at VIN+ is less than the analog input at VIN-, the output of the comparator is a digital low level. When the analog input at VIN+ is greater than the analog input VIN-, the output of the comparator is a digital high level. The shaded areas of the output of the comparator in the lower portion of Figure 24-2 demonstrate the uncertainty that is due to input offsets and the response time of the comparator.

24.3 Comparator Inputs

Depending on the Comparator Operating mode, the inputs to the comparators may be from two input pins or a combination of an input pin and one of two internal voltage references. The analog signal present at VIN- is compared to the signal at VIN+ and the digital output of the comparator is set or cleared according to the result of the comparison (see Figure 24-2).

24.3.0.1 External Reference Signal

An external voltage reference may be used with the comparator by using the output of the reference as an input to the comparator. Refer to the device data sheet for input voltage limits.

24.3.0.2 Internal Reference Signals

The CVREF module and the IVREF can be used as inputs to the comparator (see Figure 24-1). The CVREF provides a user-selectable voltage for use as a comparator reference. Refer to **25.0** "**Comparator Reference**" of this manual for more information on this module. The IVREF has a fixed, 1.2V output that does not change with the device supply voltage. Refer to the device data sheet for specific details and accuracy of this reference.

24.4 Comparator Outputs

The comparator output is read through the CMSTAT register and the COUT bit (CM2CON<8> or CM1CON<8>). This bit is read-only. The comparator output may also be directed to an I/O pin via the CxOUT bit; however, the COUT bit is still valid when the signal is routed to a pin. For the comparator output to be available on the CxOut pin, the associated TRIS bit for the output pin must be configured as an output. When the COUT signal is routed to a pin the signal is the unsynchronized output of the comparator.

The output of the comparator has a degree of uncertainty. The uncertainty of each of the comparators is related to the input offset voltage and the response time, as stated in the specifications. The lower portion of Figure 24-2 provides a graphical representation of this uncertainty.

The comparator output bit, COUT, provides the latched sampled value of the comparator's output- when the register was read. There are two common methods used to detect a change in the comparator output:

- Software polling
- · Interrupt generation

24.4.1 CHANGING THE POLARITY OF COMPARATOR OUTPUTS

The polarity of the comparator outputs can be changed using the CPOL bit (CMxCON<13>). CPOL appears below the comparator Cx on the left side of Figure 24-1.

24.5 Analog Input Connection Considerations

A simplified circuit for an analog input is shown in Figure 24-3. A maximum source impedance of 10 k Ω is recommended for the analog sources. Any external component connected to an analog input pin, such as a capacitor or a zener diode, should have very little leakage current. See the device data sheet for input voltage limits. If a pin is to be shared by two or more analog inputs that are to be used simultaneously, the loading effects of all the modules involved must be taken into consideration. This loading may reduce the accuracy of one or more of the modules connected to the common pin. This may also require a lower source impedance than is stated for a single module with exclusive use of a pin in Analog mode.

Notes: When reading the PORT register, all pins configured as analog inputs will read as a '0'. Pins configured as digital inputs will convert an analog input according to the Schmitt Trigger input specification.

Analog levels on any pin defined as a digital input may cause the input buffer to consume more current than is specified.

25.0 COMPARATOR REFERENCE

Note:	This data sheet summarizes the features of						
	the PIC32MX3XX/4XX family of devices. It						
	is not intended to be a comprehensive refer-						
	ence source. Refer to the "PIC32MX Family						
	Reference Manual" (DS61132) for a						
	detailed description of this peripheral.						

The Comparator Voltage Reference (CVREF) is a 16tap, resistor ladder network that provides a selectable reference voltage. Although its primary purpose is to provide a reference for the analog comparators, it also may be used independently of them. A block diagram of the module is shown in Figure 25-1. The resistor ladder is segmented to provide two ranges of voltage reference values and has a power-down function to conserve power when the reference is not being used. The module's supply reference can be provided from either device VDD/VSS or an external voltage reference. The CVREF output is available for the comparators and typically available for pin output. Please see the specific device data sheet for information.

The comparator voltage reference has the following features:

- · High and low range selection
- Sixteen output levels available for each range
- Internally connected to comparators to conserve device pins
- Output can be connected to a pin

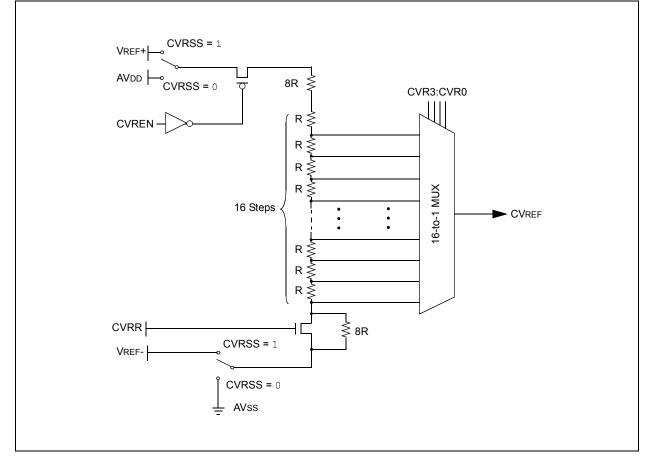

FIGURE 25-1: COMPARATOR VOLTAGE REFERENCE BLOCK DIAGRAM

25.1 Comparator Voltage Reference Control Registers

The CVREF module consists of the following Special Function Registers (SFRs):

- CVRCON: Control Register for the Module
- CVRCONCLR, CVRCONSET, CVRCONINV: atomic Bit Manipulation Registers for CVRCON

Table 25-1 provides a brief summary of all CVREF module related registers. Corresponding registers appear after the summary, followed by a detailed description of each register.

25.2 Operation

The CVREF module is controlled through the CVRCON register (Register 25-1). The CVREF provides two ranges of output voltage, each with 16 distinct levels. The range to be used is selected by the CVRR bit (CVRCON<5>). The primary difference between the ranges is the size of the steps selected by the CVREF Value Selection bits, CVR3:CVR0, with one range offering finer resolution and the other offering a wider range of output voltage. The typical output voltages are listed in Table 25-2.

The equations used to calculate the CVREF output are as follows:

```
If CVRR = 1:
Voltage
Reference = ((CVR3:CVR0)/24) x (CVRSRC)
If CVRR = 0:
Voltage
Reference = (CVRSRC/4) + ((CVR3:CVR0)/32)
x (CVRSRC)
```

The CVREF Source Voltage (CVRSRC) can come from either VDD and VSS, or the external VREF+ and VREFpins that are multiplexed with I/O pins. The voltage source is selected by the CVRSS bit (CVRCON<4>). The voltage reference is output to the CVREF pin by setting the CVROE (CVRCON<6>) bit; this will override the corresponding TRIS bit setting.

The settling time of the CVREF must be considered when changing the CVREF output (refer to the data sheet for your device).

	Voltage Reference					
CVR<3:0>	CVRR = 0 (CVRCON <5>)	CVRR = 1 (CVRCON <5>				
0	0.83V	0.00V				
1	0.93V	0.14V

14	2.27V	1.93V				
15	2.37V	2.06V				

TABLE 25-2: TYPICAL VOLTAGE REFERENCE WITH CVRsRc = 3.3

25.2.1 CVREF OUTPUT CONSIDERATIONS

The full range of voltage reference cannot be realized due to the construction of the module. The transistors on the top and bottom of the resistor ladder network (Figure 25-1) keep the voltage reference from approaching the reference source rails. The voltage reference is derived from the reference source; therefore, the voltage reference output changes with fluctuations in that source. Refer to the product data sheet for the electrical specifications. Table 25-3 contains the typical output impedances for the CVREF module.

	Voltage Reference						
CVR<3:0>	CVRR = 0 (CVRCON <5>)	CVRR = 1 (CVRCON <5>					
0	12k	500					
1	13k	1.9k					
2	13.8k	3.7k					
3	14.4k	5.3k					
4	15k	6.7k					
5	15.4k	7.9k					
6	15.8k	9k					
7	15.9k	9.9k					
8	16k	10.7k					
9	15.9k	11.3k					
10	15.8k	11.7k					
11	15.4k	11.9k					
12	15k	12k					
13	14.4k	11.9k					
14	13.8k	11.7k					
15	12.9k	11.3k					

25.2.2 INITIALIZATION

This initialization sequence, shown in Example 25-1, configures the CVREF module for: module enabled, output enabled, high range, and set output for maximum (2.37V).

EXAMPLE 25-1: VOLTAGE REFERENCE CONFIGURATION

25.3 Interrupts

There are no Interrupt configuration registers or bits for the CVREF module. The CVREF module does not generate interrupts.

25.4 I/O Pin Control

The CVREF module has the ability to output to a pin. When the CVREF module is enabled and CVROE (CVRCON<6>) is '1', the output driver for the CVREF pin is disabled and the CVREF voltage is available at the pin. For proper operation, the TRIS bit corresponding to the CVREF pin must be a '1' when CVREF is to be output to a pin. This disables the Digital Input mode for the pin and prevents undesired current draw resulting from applying an analog voltage to a digital input pin. The output buffer has very limited drive capability. An external buffer amplifier is recommended for any application that uses the CVREF voltage externally. An output capacitor may be used to reduce output noise. Use of an output capacitor will increase settling time.

26.0 WATCHDOG TIMER

Note:	This data sheet summarizes the features of
	the PIC32MX3XX/4XX of devices. It is not
	intended to be a comprehensive reference
	source. Refer to the "PIC32MX Family
	Reference Manual" (DS61132) for a
	detailed description of this peripheral.

This section describes the operation of the Watchdog Timer (WDT) and Power-up Timer of the PIC32MX3XX/4XX.

The WDT, when enabled, operates from the internal Low-Power Oscillator (LPRC) clock source and can be used to detect system software malfunctions by resetting the device if the WDT is not cleared periodically in software. Various WDT time-out periods can be selected using the WDT postscaler. The WDT can also be used to wake the device from Sleep or Idle mode. Refer to Figure 26-1.

The following are some of the key features of the WDT module:

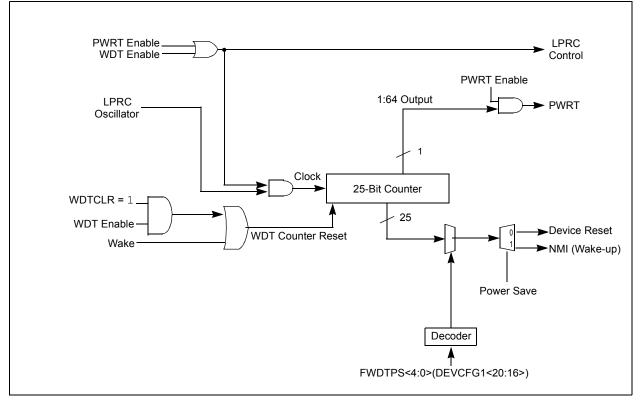

- · Configuration or software controlled
- · User-configurable time-out period
- Can wake the device from Sleep or Idle

TABLE 26-1:RESULTS OF A WDT TIME-OUT EVENT FOR AVAILABLE MODES OF DEVICE
OPERATION

Device Mode	Device Reset Generated	Non-Maskable Interrupt Generated	WDTO ⁽¹⁾ Bit Set	SLEEP ⁽¹⁾ Bit Set	IDLE ⁽¹⁾ Bit Set	Device Registers Reset
Awake	Yes	No	Yes	No	No	Yes
Sleep	No	Yes	Yes	Yes	No	No
Idle	No	Yes	Yes	No	Yes	No

Note 1: Status bits are in the RCON register.

26.2 Watchdog Timer and Power-Up Timer Operation

This describes the operation of the Watchdog Timer operation and the Power-up Timer

26.2.1 WATCHDOG TIMER OPERATION

If enabled, the WDT will increment until it overflows or "times out". A WDT time-out will force a device Reset, except during Sleep or Idle modes. To prevent a WDT time-out Reset, the user must periodically clear the Watchdog Timer by setting the WDTCLR (WDTCON<0>) bit.

The WDT uses the LPRC oscillator for reliability.

Note:	The LPRC is enabled whenever the WDT
	is enabled.

26.2.2 ENABLING AND DISABLING THE WDT

The WDT is enabled or disabled by the device configuration or controlled via software by writing to the WDTCON register.

26.2.3 DEVICE CONFIGURATION CONTROLLED WDT

If the FWDTEN Configuration bit is set, then the WDT is always enabled. The WDT ON control bit (WDTCON<15>) will reflect this by reading a '1'. In this mode, the ON bit cannot be cleared in software. This bit will not be cleared by any form of Reset. To disable the WDT in this mode, the configuration must be rewritten to the device.

Note: The default state for the WDT on an unprogrammed device is WDT enabled.

26.2.4 SOFTWARE CONTROLLED WDT

If the FWDTEN Configuration bit is a '0', then the WDT can be enabled or disabled (the default condition) by software. In this mode, the ON (WDTCON<15>) bit reflects the status of the WDT under software control. A '1' indicates the WDT is enabled and a '0' indicates it is disabled.

The WDT is enabled in software by setting the WDT ON control bit. The WDT ON control bit is cleared on any device Reset, The bit is not cleared upon a wake from Sleep or exit from Idle mode. The software WDT option allows the user to enable the WDT for critical code segments and disable the WDT during noncritical segments for maximum power savings. This bit can also be used to disable the WDT while the part is awake to eliminate the need for WDT servicing, and then re-enable it before the device is put into Idle or Sleep to wake the part at a later time.

26.2.5 WDT OPERATION IN POWER SAVE MODES

The WDT, if enabled, will continue operation in Sleep or Idle modes. The WDT may be used to wake the device from Sleep or Idle. When the WDT times out in a Power Save mode, a Non-Maskable Interrupt (NMI) is generated and the WDTO (RCON<4>) bit is set. The NMI vectors execution to the CPU start-up address but does not reset registers or peripherals. If the device was in Sleep, the SLEEP (RCON<3>) status bit will also be set. If the device was in Idle, the IDLE (RCON<2>) status bit will also be set. These bits allow the start-up code to determine the cause of the wake-up.

26.2.6 TIME DELAYS ON WAKE

There will be a time delay between the WDT event in Sleep and the beginning of code execution. The duration of this delay consists of the Start-up time for the oscillator in use and the Power-up Timer delay, if it is enabled.

Unlike a wake-up from Sleep mode, there are no time delays associated with wake-up from Idle mode. The system clock is running during Idle mode; therefore, no start-up delays are required at wake-up.

26.2.7 RESETTING THE WDT TIMER

The WDT is reset by any of the following:

- On ANY device Reset
- By a WDTCONSET = 0x01 or equivalent instruction during normal execution.
- Execution of a DEBUG command
- Exiting from Idle or Sleep due to an interrupt

Note: The WDT timer is not reset when the device enters a Power Save mode. The WDT should be serviced prior to entering a Power Save mode.

26.2.8 WDT TIMER PERIOD SELECTION

The WDT clock source is the internal LPRC oscillator, which has a nominal frequency of 32 kHz. This creates a nominal time-out period for the WDT (TWDT) of 1 millisecond when no postscaler is used.

Note:	The WDT time-out period is directly
	related to the frequency of the LPRC
	oscillator. The frequency of the LPRC
	oscillator will vary as a function of device
	operating voltage and temperature.
	Please refer to the specific
	PIC32MX3XX/4XX device data sheet for
	LPRC clock frequency specifications.

© 2008 Microchip Technology Inc.

26.2.9 WDT POSTSCALERS

The WDT has a 5-bit postscaler to create a wide variety of time-out periods. This postscaler provides 1:1 through 1: 1048576 divider ratios. Time-out periods that range between 1 ms and 1048.576 seconds (nominal) can be achieved using the postscaler.

The postscaler settings are selected using the WDTPS bits in the DEVCFG1 Configuration register. The time-out period of the WDT is calculated as follows:

EQUATION 26-1: WDT TIME-OUT PERIOD CALCULATIONS

WDT Period = $1 \text{ ms} \cdot 2^{\text{Prescaler}}$

TABLE 26-3:WDT TIME-OUT PERIOD VS.
POSTSCALER SETTINGS

FWDTPS<4:0>	Postscaler Ratio	Time-out Period
00000	1:1	1 ms

01110	1:16384	16.384 s
01111	1:32768	32.768 s
10000	1:65536	65.536 s
10001	1:131072	131.072 s
10010	1:262144	262.144 s
10011	1:524288	524.288 s
10100	1:1045876	1048.576 s

Note 1: All other combinations will result in an operation as if the prescaler was set to 10100.

2: The periods listed are based on a 32 kHz (nominal) input clock.

26.3 Interrupts and Resets

The WDT will cause an NMI or a device Reset when it expires. The Power Save mode of the device determines which event occurs. The PWRT does not generate interrupts or Resets.

26.3.1 WATCHDOG TIMER RESET

When the WDT expires and the device is not in Sleep or Idle, a device Reset is generated. The CPU code execution jumps to the device Reset vector and the Registers and Peripherals are forced to their Reset values.

To detect a WDT Reset, the WDTO (RCON<4>), SLEEP (RCON<3>) and IDLE (WDTCON<2>) bits must be tested. If the WDTO bit is a '1', the event was do to a WDT time-out. The SLEEP and IDLE bits can then be tested to determine if the WDT event occurred while the device was awake or if it was in Sleep or Idle.

26.3.2 WATCHDOG TIMER NMI

When the WDT expires in Sleep or Idle, a NMI is generated. The NMI causes the CPU code execution to jump to the device Reset vector. Though the NMI share the same vector as a device Reset, registers and peripherals are not reset.

To detect a wake from a Power Save mode by WDT, the WDTO (RCON<4>), SLEEP (RCON<3>) and IDLE (WDTCON<2>) bits must be tested. If the WDTO bit is a '1' the event was caused by a WDT time-out. The SLEEP and IDLE bits can then be tested to determine if the WDT event occurred in Sleep or Idle.

To cause a WDT time-out in Sleep to act like an interrupt, a return from interrupt instruction may be used in the start-up code after the event was determined to be a WDT wake-up. This will cause code execution to continue with the opcode following the WAIT instruction that put the device into Power Save mode. See Example 26-1.

EXAMPLE 26-1: SAMPLE WDT INITIALIZATION AND SERVICING

```
//This code fragment assumes the WDT was not enabled by the device configuration
    // The Postscaler value must be set with the device configuration
    WDTCONSET = 0x8000;// Turn on the WDT
    main
    {
        WDTCONSET = 0x01;// Service the WDT
        ... User code goes here ...
    }
```

EXAMPLE 26-2: SAMPLE CODE TO DETERMINE THE CAUSE OF A WDT EVENT

```
// sample code to determine the cause of a WDT event
// Unlock the OSCCON register
asm ("la $t3, SYSREG");//load the address of SYSREG into t3
asm ("li $t0,0xaa996655");// load Key value into t0
asm ("nor $t1, $0, $t0");// complement Key1 to form Key2
// the following writes must be performed back to back
asm ("sw $t0, 0($t3)");
                               //write Key1 to SYSREG
asm ("sw $t1, 0($t3)");
                               //write Key2 to SYSREG
// OSCCON is now unlocked
OSCCONSET = 0x10;// set power save mode to Sleep
// Alternate relock code in 'C'
SYSREG = 0x33333333;
// OSCCON is relocked
   WDTCONSET = 0x8000;//Enable WDT
   while (1)
   {
       ... user code ...
      WDTCONSET = 0x01;// service the WDT
      asm ( "wait" );// put device is selected power save mode
      // code execution will resume here after wake
      ... user code ...
   }
// The following code fragment is at the top of the device start-up code
   if ( RCON & 0x18 )
   {
      // The WDT caused a wake from sleep
      asm ( "eret" );// return from interrupt
   }
   if ( RCON & 0x14 )
   {
      // The WDT caused a wake from idle
      asm ( "eret" );// return from interrupt
   }
   if ( RCON & 0x10 )
   {
      // WDT timed-out
         (device may have been awake or may have been in sleep/idle mode)
   }
```

27.0 SPECIAL FEATURES

Note:	This data sheet summarizes the features of
	the PIC32MX3XX/4XX of devices. It is not
	intended to be a comprehensive reference
	source. Refer to the "PIC32MX Family
	Reference Manual" (DS61132) for a
	detailed description of this peripheral.

PIC32MX3XX/4XX devices include several features intended to maximize application flexibility and reliability, and minimize cost through elimination of external components. These are:

- Flexible Device Configuration
- Code Protection
- Internal Voltage Regulator

27.1 Device Configuration

In PIC32MX3XX/4XX devices, the Configuration Words select various device configurations. These Configuration Words are implemented as volatile memory registers and must be loaded from the nonvolatile programmed configuration data mapped in the last four words (32-bit x 4 words) of boot Flash memory, DEVCFG0-DEVCFG3. These are the four locations an external programming device programs with the appropriate configuration data (see Table 27-3).

Configuration Word	Address
DEVCFG0	0xBFC0_2FFC
DEVCFG1	0xBFC0_2FF8
DEVCFG2	0xBFC0_2FF4
DEVCFG3	0xBFC0_2FF0

On Power-on Reset (POR) or any Reset, the Configuration Words are copied from boot FLASH memory to their corresponding Configuration registers. A Configuration bit can only be programmed = 0 (unprogrammed state = 1). During programming, a Configuration Word can be programmed a maximum of two times before a page erase must be performed.

After programming the Configuration Words, the user should reset the device to ensure the Configuration registers are reloaded with the new programmed data.

27.1.1 CONFIGURATION REGISTER PROTECTION

To prevent inadvertent Configuration bit changes during code execution, all programmable Configuration bits are write-once. After a bit is initially programmed during a power cycle, it cannot be written to again. Changing a device configuration requires changes to the configuration data in the boot Flash memory and power to the device be cycled.

To ensure the 128-bit data integrity, a comparison is continuously made between each Configuration bit and its stored complement. If a mismatch is detected, a Configuration Mismatch Reset is generated, causing a device Reset.

27.2 Device Code Protection

The PIC32MX features a single device code protection bit, CP that when programmed = 0, protects boot Flash and program Flash from being read or modified by an external programming device. When code protection is enabled, only the Device ID registers is available to be read by an external programmer. Boot Flash and program Flash memory are not protected from self-programming during program execution when code protection is enabled. See **Section 27.3 "Program Write Protection (PWP)"**.

27.3 **Program Write Protection (PWP)**

In addition to a device code protection bit, the PIC32MX also features write protection bits to prevent boot Flash and program Flash memory regions from being written during code execution.

Boot Flash memory is write protected with a single Configuration bit, BWP (DEVCFG0<24>), when programmed = 0.

Program Flash memory can be write-protected entirely or in selectable page sizes using Configuration bits PWP<7:0> (DEVCFG0<19:12>). A page of Program Flash memory is 4096 bytes (1024 words). The PWP bits represent the one's complement of the number of protected pages. For example, programming PWP bits = 0xFF selects 0 pages to be write-protected, effectively disabling the program Flash write protection. Programming PWP bits = 0xFE selects the first page to be write protected. When enabled, the write-protected memory range is <u>inclusive</u> from the beginning of program Flash memory (0xBD00_0000) up through the selected page. Refer to Table 27-4.

Note: The PWP bits represent the one's complement of the number of protected pages.

TABLE 27-4:	FLASH PROGRAM MEMORY
	WRITE-PROTECT RANGES

PWP Bit	Range Size	Write Protected
Value	(Kbytes)	Memory Ranges ⁽¹⁾
0xFF	0	Disabled
0xFE	4	0xBD00_0FFF
0xFD	8	0xBD00_1FFF
0xFC	12	0xBD00_2FFF
0xFB	16	0xBD00_3FFF
0xFA	20	0xBD00_4FFF
0xF9	24	0xBD00_5FFF
0xF8	28	0xBD00_6FFF
0xF7	32	0xBD00_7FFF
0xF6	36	0xBD00_8FFF
0xF5	40	0xBD00_9FFF
0xF4	44	0xBD00_AFFF
0xF3	48	0xBD00_BFFF
0xF2	52	0xBD00_CFFF
0xF1	56	0xBD00_DFFF
0xF0	60	0xBD00_EFFF
0xEF	64	0xBD00_FFFF
0x7F	512	0xBD07_FFFF

Note 1: Write-protected memory range is inclusive from 0xBD00_0000.

The amount of program Flash memory available for write protection depends on the family device variant.

27.4 On-Chip Voltage Regulator

All PIC32MX3XX/4XX device's core and digital logic are designed to operate at a nominal 1.8V. To simplify system designs, most devices in the PIC32MX3XX/4XX incorporate an on-chip regulator providing the required core logic voltage from VDD.

The internal 1.8V regulator is controlled by the ENVREG pin. Tying this pin to VDD enables the regulator, which in turn provides power to the core. A low ESR capacitor (such as tantalum) must be connected to the VDDCORE/VCAP pin (Figure 27-1). This helps to maintain the stability of the regulator. The recommended value for the filer capacitor is provided in **Section 30.1 "DC Characteristics"**.

Tying the ENVREG pin to Vss disables the regulator. In this case, separate power for the core logic at a nominal 1.8V must be supplied to the device on the VDDCORE/VCAP pin.

Alternatively, the VDDCORE/VCAP and VDD pins can be tied together to operate at a lower nominal voltage. Refer to Figure 27-1 for possible configurations.

27.4.1 ON-CHIP REGULATOR AND POR

When the voltage regulator is enabled, it takes approximately 10 μ s for it to generate output. During this time, designated as TSTARTUP, code execution is disabled. TSTARTUP is applied every time the device resumes operation after any power-down, including Sleep mode.

If the regulator is disabled, a separate Power-up Timer (PWRT) is automatically enabled. The PWRT adds a fixed delay of 64 ms nominal delay at device start-up.

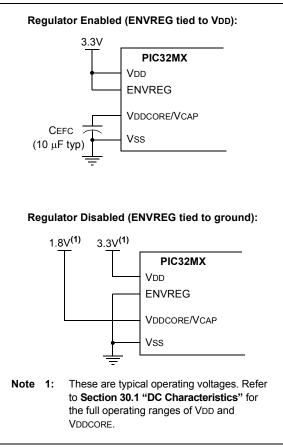

27.4.2 ON-CHIP REGULATOR AND BOR

When the on-chip regulator is enabled, PIC32MX3XX/4XX devices also have a simple brownout capability. If the voltage supplied to the regulator is inadequate to maintain a regulated level, the regulator Reset circuitry will generate a Brown-out Reset. This event is captured by the BOR flag bit (RCON<1>). The brown-out voltage levels are specific in **Section 30.1** "**DC Characteristics**".

27.4.3 POWER-UP REQUIREMENTS

The on-chip regulator is designed to meet the power-up requirements for the device. If the application does not use the regulator, then strict power-up conditions must be adhered to. While powering up, VDDCORE must never exceed VDD by 0.3 volts.

FIGURE 27-1: CONNECTIONS FOR THE ON-CHIP REGULATOR

28.0 PROGRAMMING AND DIAGNOSTICS

Note:	This data sheet summarizes the features of
	the PIC32MX3XX/4XX of devices. It is not
	intended to be a comprehensive reference
	source. Refer to the "PIC32MX Family
	Reference Manual" (DS61132) for a
	detailed description of this peripheral.

PIC32MX3XX/4XX devices provide a complete range of programming and diagnostic features that can increase the flexibility of any application using them. These features allow system designers to include:

- Simplified field programmability using two-wire In-Circuit Serial Programming™ (ICSP™) interfaces
- · Debugging using ICSP
- Programming and debugging capabilities using the EJTAG extension of JTAG
- JTAG boundary scan testing for device and board diagnostics

PIC32MX devices incorporate two programming and diagnostic modules, and a trace controller, that provide a range of functions to the application developer. They are summarized in Table 28-1.

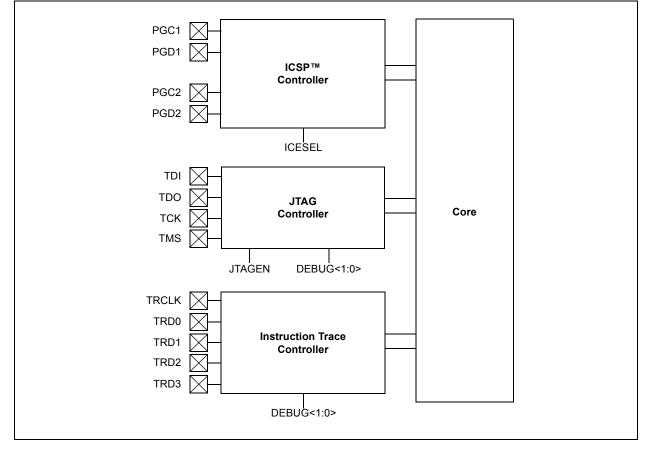

TABLE 28-1: COMPARISON OF PIC32MX3XX/4XX PROGRAMMING AND DIAGNOSTIC FEATURES FEATURES

Functions	Pins Used	Interface
Boundary Scan	TDI, TDO, TMS and TCK pins	JTAG
Programming and Debugging	TDI, TDO, TMS and TCK pins	EJTAG
Programming and Debugging	PGCx and PGDx pins	ICSP™

28.1 Control Registers

The programming and diagnostics module consists of the following Special Function Registers (SFRs):

 DDPCON: Control Register for the Diagnostic Module

DDPCONCLR, DDPCONSET, DDPCONINV: Atomic Bit Manipulation Write-Only Registers for DDPCON

• DEVCFG0: Device Configuration Register

The following table summarizes all programming and diagnostics related registers. Corresponding registers appear after the summary, followed by a detailed description of each register.

Virtual Address	Name		Bit 31/23/15/7	Bit 30/22/14/6	Bit 29/21/13/5	Bit 28/20/12/4	Bit 27/19/11/3	Bit 26/18/10/2	Bit 25/17/9/1	Bit 24/16/8/0

28.2 Operation

The PIC32MX3XX/4XX of devices has multiple programming and Debugging options including:

- · In-Circuit Serial Programming via ICSP
- In-Circuit Programming EJTAG
- · Debugging via ICSP
- · Debugging via EJTAG
- Special Debug modes for Select Communication Peripherals
- Boundary Scan

28.2.1 DEVICE PROGRAMMING OPTIONS

Note: The following sections provide a brief overview of each programming option. For more detailed information, refer to "PIC32MX Flash Programming Specification" (DS61145).

28.2.1.1 In-Circuit Serial Programming

ICSP is Microchip's proprietary solution to providing microcontroller programming in the target application. ICSP is also the most direct method to program the device, whether the controller is embedded in a system or loaded into a device programmer.

28.2.1.2 ICSP Interface

ICSP uses two pins as the core of its interface. The Programming Data (PGD) line functions as both an input and an output, allowing programming data to be read in and device information to be read out on command. The Programming Clock (PGC) line is used to clock in data and control the overall process.

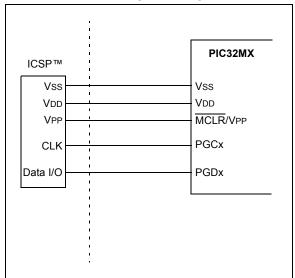

PIC32MX3XX/4XX devices have more than one pair of PGC and PGD pins; these are multiplexed with other I/O or peripheral functions. Individual ICSP pin pairs are indicated by number (e.g., PGC1/PGD1, etc.), and are generically referred to as 'PGCx' and 'PGDx'. The multiple PGCx/PGDx pairs provide additional flexibility in system design by allowing users to incorporate ICSP on the pair of pins that is least constrained by the circuit design. All PGCx and PGDx pins are functionally tied together and behave identically, and any one pair can be used for successful device programming. The only limitation is that both pins from the same pair must be used.

In addition to the PGCx and PGDx pins, ICSP requires that all voltage supply (including voltage regulator pin ENVREG) and ground pins on the device must be connected. The MCLR pin, which is used with PGCx to enter and control the programming process, must also be connected to the programmer.

A typical In-Circuit Serial Programming connection is shown in Figure 28-2.

FIGURE 28-2:

TYPICAL IN-CIRCUIT SERIAL PROGRAMMING™ CONNECTION

28.2.1.3 ICSP Operation

ICSP uses a combination of internal hardware and external control to program the target device. Programming data and instructions are provided on PGD. ICSP uses a special set of commands to control the overall process, combined with standard PIC32MX3XX/4XX instructions to execute the actual writing of the program memory. PGD also returns data to the external programmer when responding to queries.

Users who are interested in a more detailed description, or who are considering designing their own programming interface for PIC32MX3XX/4XX devices, should consult the appropriate PIC32MX3XX/4XX device programming specification.

28.2.1.4 Enhanced In-Circuit Serial Programming

The Enhanced In-Circuit Serial Programming (ICSP) protocol is an extension of the original ICSP. It uses the same physical interface as the original, but changes the location and execution of programming control to a software application written to the PIC32MX3XX/4XX device. Use of Enhanced ICSP results in significant decrease in overall programming time.

For additional information on Enhanced ICSP and the program executive, refer to the appropriate PIC32MX3XX/4XX device programming specification.

28.2.1.5 EJTAG Device Programming Using the JTAG Interface

The JTAG interface can also be used to program PIC32MX3XX/4XX devices in their target applications. Using EJTAG with the JTAG interface allows application designers to include a dedicated test and programming port into their applications, with a single 4-pin interface, without imposing the circuit constraints that the ICSP interface may require.

28.2.1.6 Enhanced EJTAG Programming Using the JTAG Interface

Enhanced EJTAG programming uses the standard JTAG interface but uses a programming executive written to RAM. Use of the programming executive with the JTAG interface provides a significant improvement in programming speed.

28.2.2 DEBUGGING

28.2.2.1 ICSP and In-Circuit Debugging

ICSP also provides a hardware channel for the In-Circuit Debugger (ICD) which allows externally controlled debugging of software. Using the appropriate hardware interface and software environment, users can force the device to single step through its code, track the actual content of multiple registers and set software breakpoints.

The active ICSP debugger port is selected by the ICS Configuration bit.

28.2.2.2 EJTAG Debugging

The industry standard EJTAG interface allows third party EJTAG tools to be used for debugging. Using the EJTAG interface, memory and registers can be viewed and modified. Breakpoints can be set and the program execution may be stopped, started or single stepped.

28.2.3 SPECIAL DEBUG MODES FOR SELECT COMMUNICATIONS PERIPHERALS

To aid in debugging applications certain I/O peripherals have a user-controllable bit to override the Freeze function in the peripheral. This allows the module to continue to send any data, buffered within the peripheral, even when a debugger attempts to halt the peripheral. The Debug mode control bits for these peripherals are contained in the DDPCON register.

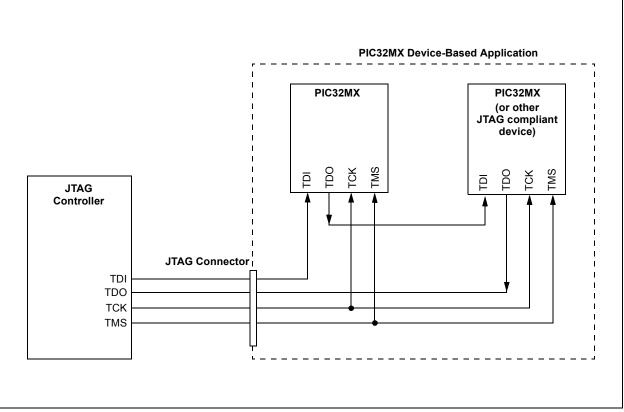

28.2.4 JTAG BOUNDARY SCAN

The JTAG boundary scan method is the process of adding a Shift register stage adjacent to each of the component's I/O pins. This permits signals at the component boundaries to be controlled and observed, using a defined set of scan test principles. An external tester or controller provides instructions and reads the results in a serial fashion. The external device also provides common clock and control signals. Depending on the implementation, access to all test signals is provided through a standardized, 4-pin interface.

A typical application incorporating the JTAG boundary scan interface is shown in Figure 28-3. In this example, a PIC32MX3XX/4XX microcontroller is daisy-chained to a second JTAG compliant device. Note that the TDI line from the external tester supplies data to the TDI pin of the first device in the chain (in this case, the microcontroller). The resulting test data for this two-device chain is provided from the TDO pin of the second device to the TDO line of the tester.

This section describes the JTAG module and its general use. Users interested in using the JTAG interface for device programming should refer to the appropriate PIC32MX3XX/4XX device programming specification for more information.

FIGURE 28-3: OVERVIEW OF PIC32MX3XX/4XX-BASED JTAG COMPLIANT APPLICATION SHOWING DAISY-CHAINING OF COMPONENTS

In PIC32MX3XX/4XX devices, the hardware for the JTAG boundary scan is implemented as a peripheral module (i.e., outside of the CPU core) with additional integrated logic in all I/O ports. A logical block diagram of the JTAG module is shown in Figure 28-1. It consists of the following key elements:

- TAP Interface Pins (TDI, TMS, TCK and TDO)
- TAP Controller
- Instruction Shift register and Instruction Register (IR)
- Data Registers (DR)

28.2.4.1 Test Access Port (TAP) and TAP Controller

The Test Access Port (TAP) on the PIC32MX3XX/4XX device is a general purpose port that provides test access to many built-in support functions and test logic defined in IEEE 1149.1. The TAP is enabled by the JTAGEN bit in the DDPCON register. The TAP is enabled, JTAGEN = 1, by default when the device exits Power-on-Reset (POR) or any device Reset. Once enabled, the designated I/O pins become dedicated TAP pins.

The PIC32MX3XX/4XX implements a 4-pin JTAG interface with these pins:

- TCK (Test Clock Input): Provides the clock for test logic.
- TMS (Test Mode Select Input): Used by the TAP to control test operations.
- TDI (Test Data Input): Serial input for test instructions and data.
- TDO (Test Data Output): Serial output for test instructions and data.

28.2.4.2 JTAG Registers

The JTAG module uses a number of registers of various sizes as part of its operation. In terms of bit count, most of the JTAG registers are single bit register cells, integrated into the I/O ports. Regardless of their location within the module, none of the JTAG registers are located within the device data memory space, and cannot be directly accessed by the user in normal operating modes.

28.2.4.3 Instruction Shift Register and Instruction Register

The Instruction Shift register is a 5-bit shift register used for selecting the actions to be performed and/or what data registers to be accessed. Instructions are shifted in, Least Significant bit first, and then decoded.

A list and description of implemented instructions is given in Section 28.2.4.6 "JTAG Instructions".

28.2.4.4 Data Registers

Once an instruction is shifted in and updated into the Instruction Register, the TAP controller places certain data registers between the TDI and TDO pins. Additional data values can then be shifted into these data registers as needed.

The PIC32MX3XX/4XX device supports three data registers:

- BYPASS Register: A single bit register which allows the boundary scan test data to pass through the selected device to adjacent devices. The BYPASS register is placed between the TDI and TDO pins when the BYPASS instruction is active.
- DEVID Register: A 32-bit part identifier. It consists of an 11-bit manufacturer ID assigned by the IEEE (29h for Microchip Technology), device part number and device revision identifier. When the IDCODE instruction is active, the device ID register is placed between the TDI and TDO pins. The device data ID is then shifted out on to the TDO pin, on the next 32 falling edges of TCK, after the TAP controller is in the Shift_DR.
- MCHP Command Shift Register: An 8-bit Shift register that is placed between the TDI and TDO pins when the MCHP_CMD instruction is active. This Shift register is used to shift in Microchip commands.

28.2.4.5 Boundary Scan Register (BSR)

The BSR is a large Shift register that is comprised of all the I/O Boundary Scan Cells (BSCs), daisy-chained together. Each I/O pin has one BSC, each containing 3 BSC registers, an input cell, an output cell and a control cell. When the SAMPLE/PRELOAD or EXTEST instructions are active, the BSR is placed between the TDI and TDO pins, with the TDI pin as the input and the TDO pin as the output.

The size of the BSR depends on the number of I/O pins on the device. For example, the 100-pin PIC32MX general purpose parts have 82 I/O pins. With 3 BSC registers for each of the 82 I/Os, this yields a Boundary Scan register length of 244 bits. This is due to the MCLR pin being an input only BSR cell. Information on the I/O port pin count of other PIC32MX3XX/4XX devices can be found in their specific device data sheets.

28.2.4.6 JTAG Instructions

PIC32MX3XX/4XX devices support the mandatory instruction set specified by IEEE 1149.1, as well as several optional public instructions defined in the specification. These devices also implement instructions that are specific to Microchip devices.

The mandatory JTAG instructions are:

- BYPASS (0x1F): Used for bypassing a device in a test chain; this allows the testing of off-chip circuitry and board level interconnections.
- SAMPLE/PRELOAD (0x02): Captures the I/O states of the component, providing a snapshot of its operation.
- EXTEST (0x06): Allows the external circuitry and interconnections to be tested, by either forcing various test patterns on the output pins, or capturing test results from the input pins.

Microchip has implemented optional JTAG instructions and manufacturer-specific JTAG commands in PIC32MX3XX/4XX devices. Please refer to Table 28-3, Table 28-4, Table 28-5 and Table 28-6.

Opcode	Name	Device Integration
0x1F	Bypass	Bypasses device in test chain
0x00	HIGHZ	Places device in a high-impedance state, all pins are forced to inputs
0x01	ID Code	Shifts out the device's ID code
0x02	Sample/Preload	Samples all pins or loads a specific value into output latch
0x06	EXTEST	Boundary scan

TABLE 28-3: JTAG COMMANDS

TABLE 28-4: MICROCHIP TAP IR COMMANDS

Opcode	Name	Device Integration
0x01	MTAP_IDCODE	Shifts out the device's ID code
0x07	MTAP_COMMAND	Configures Microchip TAP controller for DR commands
0x04	MTAP_SW_MTAP	Selects Microchip TAP controller

Opcode	Name	Device Integration
0x05	MTAP SW ETAP	Selects EJTAG TAP controller

TABLE 28-5: MICROCHIP TAP 8-BIT DR COMMANDS

Opcode	Name	Device Integration
0x00	MCHP_STATUS	Performs NOP and returns status
0xD1	MCHP_ASERT_RST	Requests Assert Device Reset
0xD0	MCHP_DE_ASSERT_RST	Requests Deassert Device Reset
0xFC	MCHP_ERASE	Performs a chip erase
0xFE	MCHP_FLASH_ENABLE	Enables fetches and loads to the Flash from the CPU
0xFD	MCHP_FLASH_DISABLE	Disables fetches and loads to the Flash from the CPU
0xFF	MCHP_READ_CONFIG	Forces device to reread the configuration settings and initialize accordingly

TABLE 28-6: EJTAG COMMANDS

Opcode	Name	Device Integration	Data Length for the Following DR
0x00		Not used	
0x01	IDCODE	Selects the device's ID Code register	32 bits
0x02		Not used	
0x03	IMPCODE	Selects Implementation register	
0x04 ⁽²⁾	MTAP_SW_MTAP	Selects Microchip TAP controller	
0x05 ⁽²⁾	MTAP_SW_ETAP	Selects EJTAG TAP controller ⁽¹⁾	
0x06-0x07		Not used	
0x08	ADDRESS	Selects the Address register	32 bits
0x09	DATA	Selects the Data register	32 bits
0x0A	CONTROL	Selects the EJTAG Control register ⁽¹⁾	32 bits
0x0B	ALL	Selects the Address, Data, EJTAG Control register ⁽¹⁾	96 bits
0x0C	EJTAGBOOT	Forces the CPU to take a debug exception after boot	1 bit
0x0D	NORMALBOOT	Makes the CPU execute the reset handler after a boot	1 bit
0x0E	FASTDATA	Selects the Data and Fast Data registers	1 bit
0x0F-0x1B		Reserved	
0x1C-0xFE		Not used	
0xFF		Selects the Bypass register	

Note 1: For complete information about EJTAG commands and protocol, refer to the EJTAG Specification available on MIPS Technologies web site, www.mips.com.

2: Not EJTAG commands but are recognized by the Microchip implementation.

28.2.5 BOUNDARY SCAN TESTING (BST)

Boundary Scan Testing (BST) is the method of controlling and observing the boundary pins of the JTAG compliant device, like those of the PIC32MX3XX/4XX, utilizing software control. BST can be used to test connectivity between devices by daisy-chaining JTAG compliant devices to form a single scan chain. Several scan chains can exist on a PCB to form multiple scan chains. These multiple scan chains can then be driven simultaneously to test many components in parallel. Scan chains can contain both JTAG compliant devices and non-JTAG compliant devices.

A key advantage of BST is that it can be implemented without physical test probes; all that is needed is a 4wire interface and an appropriate test platform. Since JTAG boundary scan has been available for many years, many software tools exist for testing scan chains without the need for extensive physical probing. The main drawback to BST is that it can only evaluate digital signals and circuit continuity; it cannot measure input or output voltage levels or currents.

28.2.5.1 Related JTAG Files

To implement BST, all JTAG test tools will require a Boundary Scan Description Language (BSDL) file. BSDL is a subset of VHDL (VHSIC Hardware Description Language), and is described as part of IEEE. 1149.1. The device-specific BSDL file describes how the standard is implemented on a particular device and how it operates.

The BSDL file for a particular device includes the following:

- The pinout and package configuration for the particular device
- The physical location of the TAP pins
- · The Device ID register and the device ID
- · The length of the Instruction Register
- The supported BST instructions and their binary codes
- The length and structure of the Boundary Scan register
- · The boundary scan cell definition

Device-specific BSDL files are available at Microchip's web site, www.microchip.com.

The name for each BSDL file is the device name and silicon revision–for example, PIC32MX3XX/4XX 320F128L_A2.BSD is the BSDL file for PIC32MX3XX/4XX 320F128L, silicon revision A2.

28.3 Interrupts

Programming and debugging operations are not performed during code execution and are therefore not affected by interrupts. Trace operations will report the change in code execution when a interrupt occurs but the trace controller is not affected by interrupts.

28.4 I/O Pins

In order to interface the numerous programming and debugging option available and still provide peripheral access to the pins, the pins are multiplexed with peripherals. Table 28-7 describes the function of the programming and debug related pins.

		Fur	nction		
Pin Name	Program Mode	Debug Mode	Trace Mode	Boundary Scan Mode	Description
MCLR	MCLR	MCLR	MCLR	MCLR	Master Clear, used to enter ICSP™ mode and to override JTAGEN (DDPCON<3>)
PGC1	PGC1/ Alternate	PGC1/ Alternate	PGC1/ Alternate	Alternate	ICSP clock, determined by ICESEL Configuration bit (DEVCFG0<3>)
PGD1	PGD1/ Alternate	PGD1/ Alternate	PGD1/ Alternate	Alternate	ICSP data, determined by ICESEL (DEVCFG0<3>) and DEBUG Configuration bits (DEVCFG0<1:0>)
PGC2	PGC2/ Alternate	PGC2/ Alternate	PGC2/ Alternate	Alternate	Alternate ICSP clock, determined by ICESEL (DEVCFG0<3>) and DEBUG Configuration bits (DEVCFG0<1:0>)
PGD2	PGD2/ Alternate	PGD2/ Alternate	PGD2/ Alternate	Alternate	Alternate ICSP data, determined by ICESEL (DEVCFG0<3>) and DEBUG Configuration bits (DEVCFG0<1:0>)
TCK	ТСК	TCK	TCK	Alternate	JTAG clock, determined by JTAGEN control bit (DDPCON<3>)
TDO	TDO	TDO	TDO	Alternate	JTAG data out, determined by JTAGEN control bit (DDPCON<3>)
TDI	TDI	TDI	TDI	Alternate	JTAG data in, determined by JTAGEN control bit (DDPCON<3>)
TMS	TMS	TMS	TMS	Alternate	JTAG test mode select, determined by JTAGEN control bit (DDPCON<3>)
TRCLK	Alternate	Alternate	TRCLK	Alternate	Trace clock, determined by TROEN control bit (DDPCON<2>)
TRD0	Alternate	Alternate	TRD0	Alternate	Trace data, determined by TROEN control bit (DDPCON<2>)
TRD1	Alternate	Alternate	TRD1	Alternate	Trace data, determined by TROEN control bit (DDPCON<2>)
TRD2	Alternate	Alternate	TRD2	Alternate	Trace data, determined by TROEN control bit (DDPCON<2>)
TRD3	Alternate	Alternate	TRD3	Alternate	Trace data, determined by TROEN control bit (DDPCON<2>)

TABLE 28-7: PROGRAMMING AND DEBUGGING PIN FUNCTIONS

NOTES:

29.0 DEVELOPMENT SUPPORT

The PIC[®] microcontrollers are supported with a full range of hardware and software development tools:

- Integrated Development Environment
 - MPLAB[®] IDE Software
- Assemblers/Compilers/Linkers
 - MPASM[™] Assembler
 - MPLAB C18 and MPLAB C30 C Compilers
 - MPLINK™ Object Linker/
 - MPLIB™ Object Librarian
 - MPLAB ASM30 Assembler/Linker/Library
- Simulators
 - MPLAB SIM Software Simulator
- · Emulators
 - MPLAB ICE 2000 In-Circuit Emulator
 - MPLAB REAL ICE™ In-Circuit Emulator
- In-Circuit Debugger
 - MPLAB ICD 2
- Device Programmers
 - PICSTART® Plus Development Programmer
 - MPLAB PM3 Device Programmer
 - PICkit[™] 2 Development Programmer
- Low-Cost Demonstration and Development Boards and Evaluation Kits

29.1 MPLAB Integrated Development Environment Software

The MPLAB IDE software brings an ease of software development previously unseen in the 8/16-bit microcontroller market. The MPLAB IDE is a Windows[®] operating system-based application that contains:

- A single graphical interface to all debugging tools
 - Simulator
 - Programmer (sold separately)
 - Emulator (sold separately)
 - In-Circuit Debugger (sold separately)
- · A full-featured editor with color-coded context
- A multiple project manager
- Customizable data windows with direct edit of contents
- · High-level source code debugging
- Visual device initializer for easy register initialization
- · Mouse over variable inspection
- Drag and drop variables from source to watch windows
- · Extensive on-line help
- Integration of select third party tools, such as HI-TECH Software C Compilers and IAR C Compilers

The MPLAB IDE allows you to:

- Edit your source files (either assembly or C)
- One touch assemble (or compile) and download to PIC MCU emulator and simulator tools (automatically updates all project information)
- · Debug using:
 - Source files (assembly or C)
 - Mixed assembly and C
 - Machine code

MPLAB IDE supports multiple debugging tools in a single development paradigm, from the cost-effective simulators, through low-cost in-circuit debuggers, to full-featured emulators. This eliminates the learning curve when upgrading to tools with increased flexibility and power.

29.2 MPASM Assembler

The MPASM Assembler is a full-featured, universal macro assembler for all PIC MCUs.

The MPASM Assembler generates relocatable object files for the MPLINK Object Linker, Intel[®] standard HEX files, MAP files to detail memory usage and symbol reference, absolute LST files that contain source lines and generated machine code and COFF files for debugging.

The MPASM Assembler features include:

- Integration into MPLAB IDE projects
- User-defined macros to streamline assembly code
- Conditional assembly for multi-purpose source files
- Directives that allow complete control over the assembly process

29.3 MPLAB C18 and MPLAB C30 C Compilers

The MPLAB C18 and MPLAB C30 Code Development Systems are complete ANSI C compilers for Microchip's PIC18 and PIC24 families of microcontrollers and the dsPIC30 and dsPIC33 family of digital signal controllers. These compilers provide powerful integration capabilities, superior code optimization and ease of use not found with other compilers.

For easy source level debugging, the compilers provide symbol information that is optimized to the MPLAB IDE debugger.

29.4 MPLINK Object Linker/ MPLIB Object Librarian

The MPLINK Object Linker combines relocatable objects created by the MPASM Assembler and the MPLAB C18 C Compiler. It can link relocatable objects from precompiled libraries, using directives from a linker script.

The MPLIB Object Librarian manages the creation and modification of library files of precompiled code. When a routine from a library is called from a source file, only the modules that contain that routine will be linked in with the application. This allows large libraries to be used efficiently in many different applications.

The object linker/library features include:

- Efficient linking of single libraries instead of many smaller files
- Enhanced code maintainability by grouping related modules together
- Flexible creation of libraries with easy module listing, replacement, deletion and extraction

29.5 MPLAB ASM30 Assembler, Linker and Librarian

MPLAB ASM30 Assembler produces relocatable machine code from symbolic assembly language for dsPIC30F devices. MPLAB C30 C Compiler uses the assembler to produce its object file. The assembler generates relocatable object files that can then be archived or linked with other relocatable object files and archives to create an executable file. Notable features of the assembler include:

- Support for the entire dsPIC30F instruction set
- · Support for fixed-point and floating-point data
- · Command line interface
- Rich directive set
- Flexible macro language
- · MPLAB IDE compatibility

29.6 MPLAB SIM Software Simulator

The MPLAB SIM Software Simulator allows code development in a PC-hosted environment by simulating the PIC MCUs and dsPIC[®] DSCs on an instruction level. On any given instruction, the data areas can be examined or modified and stimuli can be applied from a comprehensive stimulus controller. Registers can be logged to files for further run-time analysis. The trace buffer and logic analyzer display extend the power of the simulator to record and track program execution, actions on I/O, most peripherals and internal registers.

The MPLAB SIM Software Simulator fully supports symbolic debugging using the MPLAB C18 and MPLAB C30 C Compilers, and the MPASM and MPLAB ASM30 Assemblers. The software simulator offers the flexibility to develop and debug code outside of the hardware laboratory environment, making it an excellent, economical software development tool.

29.7 MPLAB ICE 2000 High-Performance In-Circuit Emulator

The MPLAB ICE 2000 In-Circuit Emulator is intended to provide the product development engineer with a complete microcontroller design tool set for PIC microcontrollers. Software control of the MPLAB ICE 2000 In-Circuit Emulator is advanced by the MPLAB Integrated Development Environment, which allows editing, building, downloading and source debugging from a single environment.

The MPLAB ICE 2000 is a full-featured emulator system with enhanced trace, trigger and data monitoring features. Interchangeable processor modules allow the system to be easily reconfigured for emulation of different processors. The architecture of the MPLAB ICE 2000 In-Circuit Emulator allows expansion to support new PIC microcontrollers.

The MPLAB ICE 2000 In-Circuit Emulator system has been designed as a real-time emulation system with advanced features that are typically found on more expensive development tools. The PC platform and Microsoft[®] Windows[®] 32-bit operating system were chosen to best make these features available in a simple, unified application.

29.8 MPLAB REAL ICE In-Circuit Emulator System

MPLAB REAL ICE In-Circuit Emulator System is Microchip's next generation high-speed emulator for Microchip Flash DSC and MCU devices. It debugs and programs PIC[®] Flash MCUs and dsPIC[®] Flash DSCs with the easy-to-use, powerful graphical user interface of the MPLAB Integrated Development Environment (IDE), included with each kit.

The MPLAB REAL ICE probe is connected to the design engineer's PC using a high-speed USB 2.0 interface and is connected to the target with either a connector compatible with the popular MPLAB ICD 2 system (RJ11) or with the new high-speed, noise tolerant, Low-Voltage Differential Signal (LVDS) interconnection (CAT5).

MPLAB REAL ICE is field upgradeable through future firmware downloads in MPLAB IDE. In upcoming releases of MPLAB IDE, new devices will be supported, and new features will be added, such as software breakpoints and assembly code trace. MPLAB REAL ICE offers significant advantages over competitive emulators including low-cost, full-speed emulation, real-time variable watches, trace analysis, complex breakpoints, a ruggedized probe interface and long (up to three meters) interconnection cables.

29.9 MPLAB ICD 2 In-Circuit Debugger

Microchip's In-Circuit Debugger, MPLAB ICD 2, is a powerful, low-cost, run-time development tool, connecting to the host PC via an RS-232 or high-speed USB interface. This tool is based on the Flash PIC MCUs and can be used to develop for these and other PIC MCUs and dsPIC DSCs. The MPLAB ICD 2 utilizes the in-circuit debugging capability built into the Flash devices. This feature, along with Microchip's In-Circuit Serial Programming[™] (ICSP[™]) protocol, offers costeffective, in-circuit Flash debugging from the graphical user interface of the MPLAB Integrated Development Environment. This enables a designer to develop and debug source code by setting breakpoints, single stepping and watching variables, and CPU status and peripheral registers. Running at full speed enables testing hardware and applications in real time. MPLAB ICD 2 also serves as a development programmer for selected PIC devices.

29.10 MPLAB PM3 Device Programmer

The MPLAB PM3 Device Programmer is a universal, CE compliant device programmer with programmable voltage verification at VDDMIN and VDDMAX for maximum reliability. It features a large LCD display (128 x 64) for menus and error messages and a modular, detachable socket assembly to support various package types. The ICSP™ cable assembly is included as a standard item. In Stand-Alone mode, the MPLAB PM3 Device Programmer can read, verify and program PIC devices without a PC connection. It can also set code protection in this mode. The MPLAB PM3 connects to the host PC via an RS-232 or USB cable. The MPLAB PM3 has high-speed communications and optimized algorithms for quick programming of large memory devices and incorporates an SD/MMC card for file storage and secure data applications.

29.11 PICSTART Plus Development Programmer

The PICSTART Plus Development Programmer is an easy-to-use, low-cost, prototype programmer. It connects to the PC via a COM (RS-232) port. MPLAB Integrated Development Environment software makes using the programmer simple and efficient. The PICSTART Plus Development Programmer supports most PIC devices in DIP packages up to 40 pins. Larger pin count devices, such as the PIC16C92X and PIC17C76X, may be supported with an adapter socket. The PICSTART Plus Development Programmer is CE compliant.

29.12 PICkit 2 Development Programmer

The PICkit[™] 2 Development Programmer is a low-cost programmer and selected Flash device debugger with an easy-to-use interface for programming many of Microchip's baseline, mid-range and PIC18F families of Flash memory microcontrollers. The PICkit 2 Starter Kit includes a prototyping development board, twelve sequential lessons, software and HI-TECH's PICC[™] Lite C compiler, and is designed to help get up to speed quickly using PIC[®] microcontrollers. The kit provides everything needed to program, evaluate and develop applications using Microchip's powerful, mid-range Flash memory family of microcontrollers.

29.13 Demonstration, Development and Evaluation Boards

A wide variety of demonstration, development and evaluation boards for various PIC MCUs and dsPIC DSCs allows quick application development on fully functional systems. Most boards include prototyping areas for adding custom circuitry and provide application firmware and source code for examination and modification.

The boards support a variety of features, including LEDs, temperature sensors, switches, speakers, RS-232 interfaces, LCD displays, potentiometers and additional EEPROM memory.

The demonstration and development boards can be used in teaching environments, for prototyping custom circuits and for learning about various microcontroller applications.

In addition to the PICDEM[™] and dsPICDEM[™] demonstration/development board series of circuits, Microchip has a line of evaluation kits and demonstration software for analog filter design, KEELOQ[®] security ICs, CAN, IrDA[®], PowerSmart battery management, SEEVAL[®] evaluation system, Sigma-Delta ADC, flow rate sensing, plus many more.

Check the Microchip web page (www.microchip.com) for the complete list of demonstration, development and evaluation kits.

30.0 ELECTRICAL CHARACTERISTICS

This section provides an overview of PIC32MX3XX/4XX electrical characteristics. Additional information will be provided in future revisions of this document as it becomes available.

Absolute maximum ratings for the PIC32MX3XX/4XX are listed below. Exposure to these maximum rating conditions for extended periods may affect device reliability. Functional operation of the device at these or any other conditions above the parameters indicated in the operation listings of this specification is not implied.

Absolute Maximum Ratings⁽¹⁾

Ambient temperature under bias	40°C to +85°C
Storage temperature	
Voltage on VDD with respect to Vss	-0.3V to +4.0V
Voltage on any combined analog and digital pin and MCLR, with respect to Vss	0.3V to (VDD + 0.3V)
Voltage on any digital only pin with respect to Vss	-0.3V to +5.5V
Voltage on VDDCORE with respect to Vss	-0.3V to 2.0V
Maximum current out of Vss pin(s)	
Maximum current into VDD pin(s) (Note 1)	
Maximum output current sunk by any I/O pin	25 mA
Maximum output current sourced by any I/O pin	25 mA
Maximum current sunk by all ports	200 mA
Maximum current sourced by all ports (Note 1)	200 mA
Note 1: Maximum allowable current is a function of device maximum power dissipation	(see Table 30-2).

Note: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operation listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

30.1 DC Characteristics

Characteristic	VDD Range	Temp Range	Max Frequency	
Characteristic	(in Volts)	(in °C)	PIC32MX3XX/4XX	
DC5	2.3-3.6V	-40°C to +85°C	80 MHz ⁽¹⁾	

TABLE 30-1: OPERATING MIPS VS. VOLTAGE

Note 1: 40 MHz maximum for PIC32MX 40MHz family variants.

TABLE 30-2: THERMAL OPERATING CONDITIONS

Rating	Symbol	Min	Тур	Мах	Unit
PIC32MX3XX/4XX					
Operating Junction Temperature Range	TJ	-40	_	+125	°C
Operating Ambient Temperature Range	TA	-40	_	+85	°C
Power Dissipation: Internal Chip Power Dissipation: PINT = VDD x (IDD - S IOH) I/O Pin Power Dissipation: I/O = S ({VDD - VOH} x IOH) + S (VOL x IOL))	PD	PINT + PI/O			W
Maximum Allowed Power Dissipation	Pdmax	(TJ — TA)/θJ	IA	W

TABLE 30-3: THERMAL PACKAGING CHARACTERISTICS

Characteristic	Symbol	Тур	Мах	Unit	Notes
Package Thermal Resistance, 100-Pin TQFP (12x12x1 mm)	θја	52.3		°C/W	1
Package Thermal Resistance, 64-Pin TQFP (10x10x1 mm)	θja	38.3	_	°C/W	1

Note 1: Junction to ambient thermal resistance, Theta-JA (θ JA) numbers are achieved by package simulations.

TABLE 30-4: DC TEMPERATURE AND VOLTAGE SPECIFICATIONS

DC25b	302	_	μA	+85°C				
DC26	_	107	μA	-40°C		7		
DC26a	_	180	μA	+25°C	3.6V			
DC26b		697	μA	+85°C	7			

TABLE 30-5: DC CHARACTERISTICS: OPERATING CURRENT (IDD)⁽¹⁾

Note 1: A device's IDD supply current is mainly a function of the operating voltage and frequency. Other factors, such as PBCLK (Peripheral Bus Clock) frequency, number of peripheral modules enabled, internal code execution pattern, execution from Program Flash memory vs. RAM, I/O pin loading and switching rate, oscillator type as well as temperature can have an impact on the current consumption.

2: The test conditions for IDD measurements are as follows: Oscillator mode = EC+PLL with OSC1 driven by external square wave from rail to rail and PBCLK divisor = 1:8. CPU, Program Flash and SRAM data memory are operational, Program Flash memory Wait states = 7 and program cache disabled. All peripheral modules are disabled (ON bit = 0). WDT and FSCM are disabled. All I/O pins are configured as inputs and pulled to Vss. MCLR = VDD.

3: Data in "Typical" column is at 3.3V, 25°C at specified operating frequency unless otherwise stated. Parameters are for design guidance only and are not tested.

TABLE 30-6: DC CHARACTERISTICS: IDLE CURRENT (IIDLE)

DC CHARACT	ERISTICS		Standard Operating Conditions: 2.3V to 3.6V(unless otherwise stated)Operating temperature $-40^{\circ}C \le TA \le +85^{\circ}C$ for Industrial

OS30	TosL, TosH	External Clock In (OSC1) High or Low Time	0.45 x Tosc	_	—	ns	EC			
OS31	TosR, TosF	External Clock In (OSC1) Rise or Fall Time		—	0.05 x Tosc	ns	EC			

Note 1: Data in "Typ" column is at 3.3V, 25°C unless otherwise stated. Parameters are for design guidance only and are not tested.

2: Instruction cycle period (TcY) equals the input oscillator time base period. All specified values are based on characterization data for that particular oscillator type under standard operating conditions with the device executing code. Exceeding these specified limits may result in an unstable oscillator operation and/or higher than expected current consumption. All devices are tested to operate at "min." values with an external clock applied to the OSC1/CLKI pin.

- **3:** 40 MHz maximum for PIC32MX 40 MHz family variants.
- 4: PLL input requirements: 4 MHz ≤ FPLLIN ≤ 5 MHz (use PLL prescaler to reduce FOSC).

Legend:	XXX	Customer-specific information		
	Y	Year code (last digit of calendar year)		
	YY	Year code (last 2 digits of calendar year)		
	WW	Week code (week of January 1 is week '01')		
	NNN	Alphanumeric traceability code		
		Pb-free JEDEC designator for Matte Tin (Sn)		
	*	This package is Pb-free. The Pb-free JEDEC designator ((e3))		
		can be found on the outer packaging for this package.		
Note:	ote: In the event the full Microchip part number cannot be marked on one line, it will			
		d over to the next line, thus limiting the number of available s for customer-specific information.		

31.2 Package Details

The following sections give the technical details of the packages.

64-Lead Plastic Thin Quad Flatpack (PT) – 10x10x1 mm Body, 2.00 mm [TQFP]

Note: For the most current package drawings, please see the Microchip Packaging Specification located at http://www.microchip.com/packaging

Notes:

- 1. Pin 1 visual index feature may vary, but must be located within the hatched area.
- 2. Chamfers at corners are optional; size may vary.

Lead Thickness

Mold Draft Angle Top

Mold Draft Angle Bottom

Lead Width

3. Dimensions D1 and E1 do not include mold flash or protrusions. Mold flash or protrusions shall not exceed 0.25 mm per side.
