ANALOG Dual-Channel Ultralow Noise Amplifier with Selectable Gain and Input Impedance

Data Sheet

FEATURES

Low noise Input voltage noise: 0.85 nV/√Hz Current noise: 2.0 pA/√Hz **High speed** 200 MHz bandwidth (G = 12.04 dB) 295 V/us slew rate Selectable gain $G = 12.04 dB (\times 4)$ G = 18.06 dB (×8) G = 21.58 dB (×12) G = 24.08 dB (×16) Active input impedance matching Integrated input clamp diodes Single-ended input, differential output Supply range: 4.5 V to 5.5 V Low power: 60 mW/channel

APPLICATIONS

CW Doppler ultrasound front ends Low noise preamplification Predriver for I/Q demodulators and phase shifters Wideband analog-to-digital drivers

GENERAL DESCRIPTION

The AD8432 is a dual-channel, low power, ultralow noise amplifier with selectable gain and active impedance matching. Each channel has a single-ended input, differential output, and integrated input clamps. By pin strapping the gain setting pins, four accurate gains of G = 12.04 dB, 18.06 dB, 21.58 dB, and 24.08 dB (×4, ×8, ×12, and ×16, respectively) are possible. A bandwidth of 200 MHz at G = 12.04 dB makes this amplifier well suited for many high speed applications.

The exceptional noise performance of the AD8432 is made possible by the active impedance matching. Using a feedback network, the input impedance of the amplifiers can be adjusted to match the signal source impedance without compromising the noise performance. Impedance matching and low noise in the AD8432 allow designers to create wider dynamic range systems that are able to detect even very low level signals. FUNCTIONAL BLOCK DIAGRAM

AD8432

The AD8432 achieves $0.85 \text{ nV}/\sqrt{\text{Hz}}$ input-referred voltage noise for a gain of 12.04 dB. The AD8432's ultralow noise, low distortion, gain accuracy, and channel-to-channel matching are ideal for high performance ultrasound systems and for processing I/Q demodulator signals.

The AD8432 operates on a single supply of 5 V at 24 mA. It is available in a 4 mm × 4 mm, 24-lead LFSCP. The LFCSP features an exposed paddle that provides a low thermal resistance path to the PCB, which enables more efficient heat transfer and increases reliability. The operating temperature range is -40° C to $+85^{\circ}$ C.

ABSOLUTE MAXIMUM RATINGS

Table 2.

Parameter	Rating
Voltage	
Supply Voltage	5.5 V
Input Voltage	0 V to VPS
Power Dissipation	120 mW
Temperature	
Operating Temperature	–40°C to +85°C
Storage Temperature	–65°C to +150°C
Package Glass Transition Temperature (T _G)	150°C
Lead Temperature (Soldering, 60 sec)	300°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

THERMAL RESISTANCE

 θ_{JA} is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages. The θ_{JA} value in Table 3 assumes a 4-layer JEDEC standard board with zero airflow.

Table 3. Thermal Resistance¹

Parameter	θ _{JA} θ _{JC}		θ _{JB}	Ψ,,	Unit
40-Lead LFCSP	57.9	11.2	35.9	1.1	°C/W

¹ 4-layer JEDEC board (2S2P).

MAXIMUM POWER DISSIPATION

The maximum safe power dissipation for the AD8432 is limited by the associated rise in junction temperature (T_1) on the die. At approximately 150°C, which is the glass transition temperature, the properties of the plastic change. Even temporarily exceeding this temperature limit may change the stresses that the package exerts on the die, permanently shifting the parametric performance of the amplifiers. Exceeding a temperature of 150°C for an extended period can cause changes in silicon devices, potentially resulting in a loss of functionality.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

THEORY OF OPERATION LOW NOISE AMPLIFIER (LNA)

The AD8432 is a dual-channel, ultralow noise amplifier with integrated pin-strappable, gain-setting resistors. The resistors can be externally connected to achieve differential gains of 12.04 dB, 18.06 dB, 21.58 dB, and 24.08 dB (\times 4, \times 8, \times 12, and \times 16, respectively). A simplified schematic of an LNA is shown in Figure 65.

The LNA is driven with a single-ended input and measured differentially at the output. The inverting input INL must be ac-coupled to ground through a capacitor for proper operation. The LNA cannot be driven differentially due to the asymmetry of the internal gain setting resistors. The gain from the inverting input INL to the single-ended output (OPH or OPL) does not match the gain from the noninverting input INH to the singleended output.

The AD8432 inputs have a dc bias voltage of 3.25 V, which is generated internally. The inputs must be ac-coupled through a series capacitor to maintain the dc bias level of the inputs. Likewise, the AD8432 outputs have a dc bias voltage of 2.5 V. An ac coupling capacitor in series with each single-ended output is recommended to prevent improper loading of the outputs. The AD8432 inputs have a dc bias voltage of 3.25 V, which is generated internally. The inputs must be ac-coupled through a series capacitor to maintain the dc bias level of the inputs (see CINL and CINH in Figure 65).

The AD8432 supports a differential output voltage of 4.8 V p-p for the common-mode output voltage of 2.5 V. Therefore, for a

differential gain of G = 12.04 dB, the maximum input voltage allowed is 1.2 V p-p.

Clamping the inputs ensures quick recovery from large input voltages. The input back-to-back diodes, which are integrated inside the die (IND1 and IND2), should be used for the lowest gain configuration (12.04 dB) to protect the input from overdriving. They should be connected after the source resistance or before the INH coupling capacitor.

The use of a fully differential topology and negative feedback minimizes distortion. A differential signal enables smaller swings at each output, which results in reduction of third-order distortion.

The AD8432 is a voltage feedback amplifier. Due to gain bandwidth product (GBW), a decrease in bandwidth should be expected as the gain increases. Table 5 displays the values of the -3 dB bandwidth for each gain with unterminated input impedance.

GAIN SETTING TECHNIQUE

Pin strapping is used to set the gain of the amplifier. Gain setting resistors are integrated in the LNA and are accessible externally through the GOH, GMH, GML, and GOL pins. By externally shorting these pins, and thereby shorting or connecting the internal resistors, the AD8432 can be configured for four different gains. Table 5 shows which pins must be connected to achieve the desired gain.

Figure 65. Simplified Schematic of a Single LNA Channel, Including External Shunt and Feedback Components

Differential Gain (dB)	Single Gain (dB)	–3 dB BW (MHz)	RG1 (Ω)	RG2 (Ω)	RG3 (Ω)	RG4 (Ω)	RG5 (Ω)	RG6 (Ω)	RG7 (Ω)
12.04	6.02	200	12	12	Connect GMH to GOH	Connect GOH to OPH	24	Connect GML to GOL	Connect GOL to OPL
18.06	12.04	90	12	12	24	Connect GOH to OPH	24	24	Connect GOL to OPL
21.58	15.56	50	12	12	Connect GMH to GOH	48	24	Connect GML to GOL	48
24.08	18.06	32	12	12	24	48	24	24	48

Table 5. Gain Setting Using a Pin-Strapping Technique and -3 dB Bandwidth for Each Gain Configuration

The single-ended gain from INH to OPH (see Figure 65) is defined as

$$G_{OPH-INH} = \frac{R_{G1} + R_{G2} + R_{G3} + R_{G4}}{R_{G1}}$$

The single-ended gain from INH to OPL is defined as

 $G_{OPL-INH} = -\frac{R_{G5} + R_{G6} + R_{G7}}{R_{GI}}$

The values of the seven gain resistors were chosen so that both single-ended gains are equal. For example, to set a gain of 12.04 dB (G = \times 4) differentially, the gain from INH to each output (OPH, OPL) should be 6.02 dB (G = \times 2).

INH to OPH: For $R_{G1} = R_{G2} = R_G$, then

$$G_{OPH-INH} = \frac{R_{G1} + R_{G2}}{R_{G1}} = \frac{2 \times R_G}{R_G} = 2$$

INH to OPL: For $R_{G1} = R_G$ and $R_{G5} = 2 \times R_G$, then

$$G_{OPL-INH} = -\frac{R_{G5}}{R_{G1}} = -\frac{2 \times R_G}{R_G} = -2$$

ACTIVE INPUT RESISTANCE MATCHING

The AD8432 reduces noise and optimizes signal power transfer by using active input termination to perform signal source resistance matching.

The primary purpose of input impedance matching is to optimize the input signal power transfer. With resistive termination, the input noise increases due to the thermal noise of the terminating resistor and the increased contribution of the input voltage noise generator of the LNA. With active impedance matching, however, the contributions of both are smaller than they are for resistive termination by a factor of $1/(1 + \frac{1}{2} \text{ LNA})$ gain. The noise figure (NF) for the three terminating schemes is shown in Figure 67.

Figure 66. Input Resistance Matching

To achieve this active impedance match, connect a feedback resistor, R_{FB} , between the INH and OPL (see Figure 66). R_{IN} is given in Equation 1, where G/2 is the single-ended gain.

 R_{D}

$$_{N} = \frac{R_{FB}}{1 + \frac{G}{2}} \tag{1}$$

In addition, to further reduce the input resistance, there is an internal resistance of 6.2 k Ω in parallel with the source resistance, such that

$$R_{IN} = \frac{R_{FB}}{1 + \frac{G}{2}} \left\| R_{INTERNAL} \right\|$$
(2)

Equation 3 should be used to calculate $R_{\rm FB}$ accurately for a desired input resistance and single-ended gain. Refer to Table 6 for calculated results for $R_{\rm FB}$ for several input resistance and gain combinations.

$$\Rightarrow R_{FB} = \frac{R_{IN} \left(1 + \frac{G}{2}\right)}{1 - \frac{R_{IN}}{R_{INTERNAL}}}, R_{INTERNAL} = 6.2 \text{ k}\Omega$$
(3)

Figure 67. Noise Figure vs. R_s for Resistive, Active Match, and Unterminated Inputs

Figure 68. Noise Figure vs. R_s for Various Values of R_{IN}, Actively Matched

The user must determine the level of matching accuracy desired and adjust R_{FB} accordingly. The R_{FB} and C_{FB} network presents a load to OPL that OPH does not see. The user can add an identical load on OPH to improve slightly the distortion caused by this imbalance.

There is a feedback capacitor (C_{FB}) in series with R_{FB} (see Figure 65) because the dc levels of the positive output and the positive input are different. At higher frequencies, the value of the feedback capacitor must be considered.

The unterminated bandwidth ($R_{FB} = \infty$) is 200 MHz. The AD8432 has a low input-referred voltage noise of 0.85 nV/ \sqrt{Hz} at the lowest gain, 12.04 dB (unterminated configuration). To achieve such low noise, the dual amplifier consumes 24 mA, resulting in a power consumption of 120 mW.

APPLICATIONS INFORMATION

The AD8432 LNA provides precision gain and ultralow noise performance with minimal external components. Because it is a high performance part, care must be taken to ensure that it is configured optimally to attain the best performance and dynamic range for the system.

TYPICAL SETUP

The internal bias circuitry of the AD8432 sets the input bias voltage at 3.25 V and the output bias voltage at 2.5 V. It is important to ac couple the inputs through a capacitor to maintain the internal dc bias levels. When active input termination is used (R_{FB}), a decoupling capacitor (C_{FB}) is required to isolate the input and output bias voltages of the LNA. A typical value for C_{FB} is 0.1 µF, but a smaller value capacitor is more appropriate at higher frequencies.

The unterminated input impedance of the AD8432 is 6.2 k Ω . Any input resistance between 50 Ω and 6.2 k Ω can be synthesized using active impedance matching.

At the lowest gain (12.04 dB), the gain response exhibits some peaking at higher frequencies. A resistor-capacitor shunt network (RC) at the input (see RSHx and CSHx in Figure 69) is recommended to reduce gain peaking and enhance stability at higher frequencies.

Table 7 shows the recommended values of $\rm R_{FB}, \rm C_{SH},$ and $\rm R_{SH}$ for all four gains and several input impedance combinations. The values for the $\rm C_{SH}$ and $\rm R_{SH}$ network are determined empirically and can be customized as needed to optimize performance. As $\rm R_{IN}$ increases, the value of $\rm C_{SH}$ diminishes, and for higher input impedance values, no capacitor may be required.

I/Q DEMODULATION FRONT END

The AD8432 low noise amplifiers can be used to drive the differential RF inputs of the dual AD8333 or the quad AD8339 I/Q demodulators. The primary application for the AD8339 is phased array beamforming in medical ultrasound, specifically in CW Doppler processing. Other applications include phased array radar and smart antennas for mobile communications.

Figure 70. Block Diagram of AD8432 and AD8339 Application for Ultrasound Beamforming

Because of its low output noise and low distortion, the AD8432 ensures minimal degradation in dynamic range while amplifying the RF input signal. At the lowest gain of 12.04 dB, the AD8432 contributes only $3.4 \text{ nV}/\sqrt{\text{Hz}}$ output voltage noise.

Figure 70 shows a simplified block diagram of one channel of the AD8432 driving the AD8339. The AD8432 outputs can be connected directly to the AD8339 RF inputs through 20 Ω resistors. A differential clock signal, 4LO, which is applied to the

4LOP and 4LON pins of the AD8339, has a frequency 4× that of the RF inputs. The AD8339 downconverts the RF signals, generates quadrature, and phase-shifts the resultant I and Q signals.

The I and Q outputs of the AD8339 are current outputs. A transimpedance amplifier, such as the AD8021, processes the outputs and performs several functions, including the following:

- Current-to-voltage conversion
- Summation amplifier for multiple channels
- Active low-pass filter

In beamforming applications, the I and Q outputs of a number of receiver channels are summed, which increases the system dynamic range by 10 \log_{10} (N), where N is the number of channels being summed. The external RC feedback network of the AD8021 is a 100 kHz low-pass filter as shown in Figure 70. See the AD8333 and AD8339 datasheets for more details on implementing I/Q demodulators.

Evaluation boards are available for the AD8432 and the AD8339 to facilitate system level design and testing. A detailed reference schematic of the setup is shown in Figure 71. The AD8432 is shown in this configuration with a gain of 12.04 dB, with unterminated inputs. If active termination is preferred, use an R_{FB} and C_{FB} network as discussed in the Theory of Operation section. The IND1/IND2 clamping diodes can be connected to IN1/IN2 to protect the LNA input from being overdriven.

Figure 71. Schematic of the AD8432 (G = 12.04 dB) and AD8339 Application for Ultrasound Beamforming

DIFFERENTIAL-TO-SINGLE-ENDED CONVERSION

Some applications require the low noise and high dynamic range of the AD8432; however, they may also require a singleended output, rather than a differential output. The AD8129 or AD8130 differential receiver amplifier can be used for the differential-to-single-ended conversion of the AD8432 output, as shown in Figure 72.

The AD8129 is a low noise, high gain (10 or greater) amplifier intended for applications over very long cables, where signal attenuation is significant. The AD8130 is stable at a gain of 1 and can be used for applications where lower gains are required. The AD8129 and AD8130 have user-adjustable gain, set by the ratio of two resistors, to help compensate for losses in the transmission line. A transformer or balun can also be used to convert the differential output of the AD8432 to a single-ended output. Transformers have lower distortion; however, care must be taken to properly match the impedance of the transformer. The test circuit for distortion measurements in Figure 58 uses an ADTT1-1 transformer to perform differential-to-single-ended conversion.

EVALUATION BOARD

Figure 73 is a photo of the AD8432 evaluation board. Completely assembled and pretested, the board provides convenient and fast verification of system design and to assess the performance of the AD8432 under user-specific operating conditions. The remainder of this section describes the operation and construction of the board.

Figure 74 through Figure 79 are various artwork and assembly views and Figure 80 shows the schematic diagram. The board provides access to the inputs, the outputs, and the gain settings. As shipped, the board is configured for a gain of 21 dB and 50 Ω input termination. Multiple combinations of gain and impedance matching are available to the user.

Figure 73. Evaluation Board

CONNECTION AND OPERATION

Power Supply

The AD8432 requires only a single 5 V supply connected to the +5V red test loop and black test loop GND next to it. Separate power pins are provided for the two LNA channels, but the two amplifier sections are wired together and rf-decoupled by small inductors as a precaution. The remaining red test loops are for pin probing as necessary. Should the need for amplifier isolation arise, simply un-power the unneeded amplifier by removing L3 or L4. (Refer to Figure 74 and Figure 80.

Input Termination

The AD8432 features active input termination and boards are shipped for 50 Ω . The input impedance is determined by the LNA gain, and the feedback resistors R_{FB1} and R_{FB2} (see the schematic in Figure 80) and source impedance (refer to the Theory of Operation section and Table 7). C_{FB} provides the necessary ac coupling between the input and output when using active termination; a 0.1 μ F capacitor is recommended. The R_{FB} and C_{FB} network presents a load to the OPL; if needed, an equivalent load at OPH balances the differential output.

Switches CLAMP1 and CLAMP2 connect the input clamping diodes (IND1 and IND2) across the signal path. The diodes provide input overvoltage protection in applications where fast transient pulses exceeding 5.5 V or less than –0.6 V are present. Clamping diodes enable faster overdrive recovery times, especially at the lowest gain (12.04 dB). Fast transients are usually not fatal to the device, which features ESD protection in any event.

Setting the Amplifier Gain

The violet test loops OPnn, GOnn and GMnn and Resistors R1–R4 and Resistors R9–R12 are provided for gain adjustment. Install 0 Ω resistors to reduce gain, leaving the positions open to increase gain. As shipped, the evaluation board is configured for G = 21 dB (12×). Table 8 lists the configuration for the four available LNA gain values.

Table 8. Gain Setting Configuration

INA1	LNA2	GAIN dB(×)			
LNAI		8(4)	18(8)	21(12)	24(16)
R1	R9	Y ¹	Y ¹	open	open
R2	R10	Y ¹	open	Y ¹	open
R3	R11	Y ¹	open	Y ¹	open
R4	R12	Y ¹	Y ¹	open	open

¹ Y = Install 0 Ω .

Output

The 4-pin headers PR1OUT and PR2OUT are placed close to the AD8432, and provide a way for monitoring the differential output or the single-ended output using a high impedance differential probe. The two inner pins of the headers are connected to OPL/OPH, and the two outer pins of the headers are connected to ground.
