

FEATURES

- Industry-standard-compatible pinout**
- High current drive capability**
- Precise UVLO comparator with hysteresis**
- 3.3 V-compatible inputs**
- 10 ns typical rise time and fall time at 2.2 nF load**
- Matched propagation delays between channels**
- Fast propagation delay**
- 4.5 V to 18 V supply voltage**
- Parallelable dual outputs**
- Rated from -40°C to $+125^{\circ}\text{C}$ junction temperature**
- Thermally enhanced packages, 8-lead SOIC_N_EP and 8-lead MINI_SO_EP**

APPLICATIONS

- AC-to-dc switch mode power supplies**
- DC-to-dc power supplies**
- Synchronous rectification**
- Motor drives**

GENERAL DESCRIPTION

The ADP3654 high current and dual high speed driver is capable of driving two independent N-channel power MOSFETs. The driver uses the industry-standard footprint but adds high speed switching performance.

The wide input voltage range allows the driver to be compatible with both analog and digital PWM controllers.

Digital power controllers are powered from a low voltage supply, and the driver is powered from a higher voltage supply. The ADP3654 driver adds UVLO and hysteresis functions, allowing safe startup and shutdown of the higher voltage supply when used with low voltage digital controllers.

The driver is available in thermally enhanced SOIC_N_EP and MINI_SO_EP packaging to maximize high frequency and current switching in a small printed circuit board (PCB) area.

ABSOLUTE MAXIMUM RATINGS

Table 2.

| Parameter | Rating |
|--|----------------------------|
| VDD | −0.3 V to +20 V |
| OUTA, OUTB | |
| DC | −0.3 V to $V_{DD} + 0.3$ V |
| <200 ns | −2 V to $V_{DD} + 0.3$ V |
| INA, INB | −0.3 V to $V_{DD} + 0.3$ V |
| ESD | |
| Human Body Model (HBM) | 3.5 kV |
| Field Induced Charged Device Model (FICDM) | |
| SOIC_N_EP | 1.5 kV |
| MINI_SO_EP | 1.0 kV |
| θ_{JA} , JEDEC 4-Layer Board | |
| SOIC_N_EP ¹ | 59°C/W |
| MINI_SO_EP ¹ | 43°C/W |
| Junction Temperature Range | −40°C to +150°C |
| Storage Temperature Range | −65°C to +150°C |
| Lead Temperature | |
| Soldering (10 sec) | 300°C |
| Vapor Phase (60 sec) | 215°C |
| Infrared (15 sec) | 260°C |

¹ θ_{JA} is measured per JEDEC standards, JESD51-2, JESD51-5, and JESD51-7, as appropriate with the exposed pad soldered to the PCB.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device.

Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

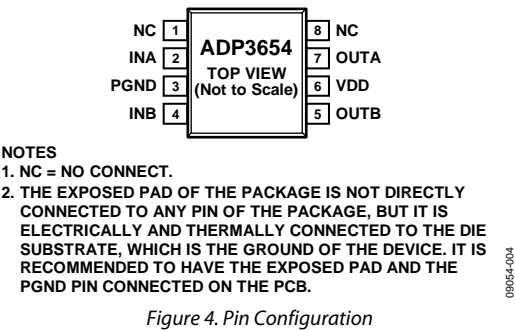

Table 3. Pin Function Descriptions

| Pin No. | Mnemonic | Description |
|---------|----------|---|
| 1 | NC | No Connect. |
| 2 | INA | Input Pin for Channel A Gate Driver. |
| 3 | PGND | Ground. This pin should be closely connected to the source of the power MOSFET. |
| 4 | INB | Input Pin for Channel B Gate Driver. |
| 5 | OUTB | Output Pin for Channel B Gate Driver. |
| 6 | VDD | Power Supply Voltage. Bypass this pin to PGND with a ~1 μ F to 5 μ F ceramic capacitor. |
| 7 | OUTA | Output Pin for Channel A Gate Driver. |
| 8 | NC | No Connect. |
| 9 | EPAD | Exposed Pad. The exposed pad of the package is not directly connected to any pin of the package, but it is electrically and thermally connected to the die substrate, which is the ground of the device. It is recommended to have the exposed pad and the PGND pin connected on the PCB. |

TYPICAL PERFORMANCE CHARACTERISTICS

$V_{DD} = 12\text{ V}$, $T_J = 25^\circ\text{C}$, unless otherwise noted.

THEORY OF OPERATION

The ADP3654 dual driver is optimized for driving two independent enhancement N-channel MOSFETs or insulated gate bipolar transistors (IGBTs) in high switching frequency applications.

These applications require high speed, fast rise and fall times, as well as short propagation delays. The capacitive nature of the aforementioned gated devices requires high peak current capability as well.

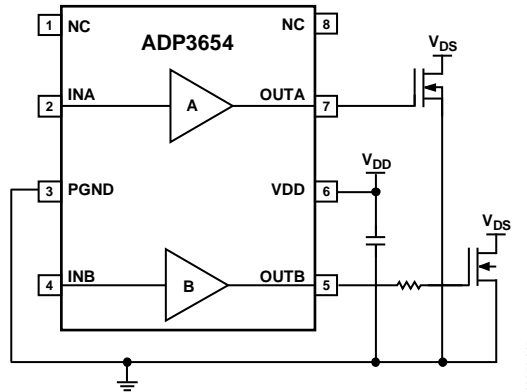

Figure 15. Typical Application Circuit

INPUT DRIVE REQUIREMENTS (INA AND INB)

The ADP3654 is designed to meet the requirements of modern digital power controllers; the signals are compatible with 3.3 V logic levels. At the same time, the input structure allows for input voltages as high as V_{DD} .

An internal pull-down resistor is present at the input, which guarantees that the power device is off in the event that the input is left floating.

LOW-SIDE DRIVERS (OUTA, OUTB)

The ADP3654 dual drivers are designed to drive ground referenced N-channel MOSFETs. The bias is internally connected to the V_{DD} supply and PGND.

When ADP3654 is disabled, both low-side gates are held low. Internal impedance is present between the OUTA pin and GND and between the OUTB pin and GND; this feature ensures that the power MOSFET is normally off when bias voltage is not present.

When interfacing ADP3654 to external MOSFETs, the designer should consider ways to make a robust design that minimizes stresses on both the driver and the MOSFETs. These stresses include exceeding the short time duration voltage ratings on the OUTA and OUTB pins, as well as the external MOSFET.

Power MOSFETs are usually selected to have a low on resistance to minimize conduction losses, which usually implies a large input gate capacitance and gate charge.

SUPPLY CAPACITOR SELECTION

For the supply input (V_{DD}) of the ADP3654, a local bypass capacitor is recommended to reduce the noise and to supply some of the peak currents that are drawn.

An improper decoupling can dramatically increase the rise times because excessive resonance on the OUTA and OUTB pins can, in some extreme cases, damage the device, due to inductive overvoltage on the V_{DD} , OUTA, or OUTB pin.

The minimum capacitance required is determined by the size of the gate capacitances being driven, but as a general rule, a 4.7 μF , low ESR capacitor should be used. Multilayer ceramic chip (MLCC) capacitors provide the best combination of low ESR and small size. Use a smaller ceramic capacitor (100 nF) with a better high frequency characteristic in parallel to the main capacitor to further reduce noise.

Keep the ceramic capacitor as close as possible to the ADP3654 device and minimize the length of the traces going from the capacitor to the power pins of the device.

PCB LAYOUT CONSIDERATIONS

Use the following general guidelines when designing PCBs:

- Trace out the high current paths and use short, wide (>40 mil) traces to make these connections.
- Minimize trace inductance between the OUTA and OUTB outputs and MOSFET gates.
- Connect the PGND pin of the ADP3654 device as closely as possible to the source of the MOSFETs.
- Place the V_{DD} bypass capacitor as close as possible to the V_{DD} and PGND pins.
- Use vias to other layers, when possible, to maximize thermal conduction away from the IC.

ADP3654

Figure 16 shows an example of the typical layout based on the preceding guidelines.

Figure 16. External Component Placement Example

Note that the exposed pad of the package is not directly connected to any pin of the package, but it is electrically and thermally connected to the die substrate, which is the ground of the device.

PARALLEL OPERATION

The two driver channels present in the ADP3654 device can be combined to operate in parallel to increase drive capability and minimize power dissipation in the driver.

The connection scheme is shown in Figure 17. In this configuration, INA and INB are connected together, and OUTA and OUTB are connected together.

Particular attention must be paid to the layout in this case to optimize load sharing between the two drivers.

Figure 17. Parallel Operation

THERMAL CONSIDERATIONS

When designing a power MOSFET gate drive, the maximum power dissipation in the driver must be considered to avoid exceeding maximum junction temperature.

Data on package thermal resistance is provided in Table 2 to help the designer with this task.

There are several equally important aspects that must be considered, such as the following:

- Gate charge of the power MOSFET being driven
- Bias voltage value used to power the driver
- Maximum switching frequency of operation
- Value of external gate resistance
- Maximum ambient (and PCB) temperature
- Type of package

All of these factors influence and limit the maximum allowable power dissipated in the driver.

The gate of a power MOSFET has a nonlinear capacitance characteristic. For this reason, although the input capacitance is usually reported in the MOSFET data sheet as C_{iss} , it is not useful to calculate power losses.

The total gate charge necessary to turn on a power MOSFET device is usually reported on the device data sheet under Q_G . This parameter varies from a few nanocoulombs (nC) to several hundred nC, and is specified at a specific V_{GS} value (10 V or 4.5 V).

The power necessary to charge and then discharge the gate of a power MOSFET can be calculated as:

$$P_{GATE} = V_{GS} \times Q_G \times f_{SW}$$

where:

V_{GS} is the bias voltage powering the driver (VDD).

Q_G is the total gate charge.

f_{SW} is the maximum switching frequency.

The power dissipated for each gate (P_{GATE}) still needs to be multiplied by the number of drivers (in this case, 1 or 2) being used in each package, and it represents the total power dissipated in charging and discharging the gates of the power MOSFETs.

Not all of this power is dissipated in the gate driver because part of it is actually dissipated in the external gate resistor, R_G . The larger the external gate resistor is, the smaller the amount of power that is dissipated in the gate driver.

In modern switching power applications, the value of the gate resistor is kept at a minimum to increase switching speed and minimize switching losses.

In all practical applications where the external resistor is in the order of a few ohms, the contribution of the external resistor can be neglected, and the extra loss is assumed in the driver, providing a good guard band to the power loss calculations.

In addition to the gate charge losses, there are also dc bias losses, due to the bias current of the driver. This current is present regardless of the switching.

$$P_{DC} = V_{DD} \times I_{DD}$$

The total estimated loss is the sum of P_{DC} and P_{GATE} .

$$P_{LOSS} = P_{DC} + (n \times P_{GATE})$$

where n is the number of gates driven.

When the total power loss is calculated, the temperature increase can be calculated as

$$\Delta T_J = P_{LOSS} \times \theta_{JA}$$

Design Example

For example, consider driving two IRFS4310Z MOSFETs with a V_{DD} of 12 V at a switching frequency of 300 kHz, using an ADP3654 in the SOIC_N_EP package.

The maximum PCB temperature considered for this design is 85°C.

From the MOSFET data sheet, the total gate charge is $Q_G = 120$ nC.

$$P_{GATE} = 12 \text{ V} \times 120 \text{ nC} \times 300 \text{ kHz} = 432 \text{ mW}$$

$$P_{DC} = 12 \text{ V} \times 1.2 \text{ mA} = 14.4 \text{ mW}$$

$$P_{LOSS} = 14.4 \text{ mW} + (2 \times 432 \text{ mW}) = 878.4 \text{ mW}$$

The SOIC_N_EP thermal resistance is 59°C/W.

$$\Delta T_J = 878.4 \text{ mW} \times 59^\circ\text{C/W} = 51.8^\circ\text{C}$$

$$T_J = T_A + \Delta T_J = 136.8^\circ\text{C} \leq T_{JMAX}$$

This estimated junction temperature does not factor in the power dissipated in the external gate resistor and, therefore, provides a certain guard band.

If a lower junction temperature is required by the design, the MINI_SO_EP package can be used, which provides a thermal resistance of 43°C/W, so that the maximum junction temperature is

$$\Delta T_J = 878.4 \text{ mW} \times 43^\circ\text{C/W} = 37.7^\circ\text{C}$$

$$T_J = T_A + \Delta T_J = 122.7^\circ\text{C} \leq T_{JMAX}$$

Other options to reduce power dissipation in the driver include reducing the value of the V_{DD} bias voltage, reducing switching frequency, and choosing a power MOSFET with smaller gate charge.
