

## PFM/PWM Step-Up DC/DC Controller

### Features

- Assured Start-up at 0.9V
- 50 $\mu$ A (Typ) Supply Current ( $f_{OSC} = 100\text{kHz}$ )
- 300mA Output Current @  $V_{IN} \geq 2.7\text{V}$
- 0.5 $\mu$ A Shutdown Mode
- 100kHz and 300kHz Switching Frequency Options
- Programmable Soft-Start
- 84% Typical Efficiency
- Small Package: 5-Pin SOT-23A

### Applications

- Palmtops
- Battery-Operated Systems
- Positive LCD Bias Generators
- Portable Communicators

### Device Selection Table

Part Number	Output Voltage (V)*	Package	Osc. Freq. (kHz)	Operating Temp. Range
TC110501ECT	5.0	5-Pin SOT-23A	100	-40°C to +85°C
TC110331ECT	3.3	5-Pin SOT-23A	100	-40°C to +85°C
TC110301ECT	3.0	5-Pin SOT-23A	100	-40°C to +85°C
TC110503ECT	5.0	5-Pin SOT-23A	300	-40°C to +85°C
TC110333ECT	3.3	5-Pin SOT-23A	300	-40°C to +85°C
TC110303ECT	3.0	5-Pin SOT-23A	300	-40°C to +85°C

\*Other output voltages are available. Please contact Microchip Technology Inc. for details.

### Package Type

### General Description

The TC110 is a step-up (Boost) switching controller that furnishes output currents of up to 300mA while delivering a typical efficiency of 84%. The TC110 normally operates in pulse width modulation mode (PWM), but automatically switches to pulse frequency modulation (PFM) at low output loads for greater efficiency. Supply current draw for the 100kHz version is typically only 50 $\mu$ A, and is reduced to less than 0.5 $\mu$ A when the SHDN input is brought low. Regulator operation is suspended during shutdown. The TC110 accepts input voltages from 2.0V to 10.0V, with a guaranteed start-up voltage of 0.9V.

The TC110 is available in a small 5-Pin SOT-23A package, occupies minimum board space and uses small external components (the 300kHz version allows for less than 5mm surface-mount magnetics).

**3:**  $V_R$  is the factory output voltage setting.

## 2.0 PIN DESCRIPTIONS

The descriptions of the pins are listed in Table 2-1.

**TABLE 2-1: PIN FUNCTION TABLE**

Pin No. (5-Pin SOT-23A)	Symbol	Description
1	$V_{OUT}$	Internal device power and voltage sense input. This dual function input provides both feedback voltage sensing and internal chip power. It should be connected to the regulator output. (See Section 4.0, Applications).
2	$V_{DD}$	Power supply voltage input.
3	$\overline{SHDN/SS}$	Shutdown input. A logic low on this input suspends device operation and supply current is reduced to less than 0.5 $\mu$ A. The device resumes normal operation when $\overline{SHDN}$ is again brought high. An RC circuit connected to this input also determines the soft-start time.
4	GND	Ground terminal.
5	EXT	External switch transistor drive complimentary output. This pin drives the external switching transistor. It may be connected to the base of the external bipolar transistor or gate of the external N-channel MOSFET. (See Section 4.0, Applications).

## 3.0 DETAILED DESCRIPTION

The TC110 is a PFM/PWM step-up DC/DC controller for use in systems operating from two or more cells, or in low voltage, line-powered applications. It uses PWM as the primary modulation scheme, but automatically converts to PFM at output duty cycles less than approximately 25%. The conversion to PFM provides reduced supply current, and therefore higher operating efficiency at low loads. The TC110 uses an external switching transistor, allowing construction of switching regulators with maximum output currents of 300mA.

The TC110 consumes only 70 $\mu$ A, typical, of supply current and can be placed in a 0.5 $\mu$ A shutdown mode by bringing the shutdown input ( $\overline{\text{SHDN}}$ ) low. The regulator remains disabled while in shutdown mode, and normal operation resumes when  $\overline{\text{SHDN}}$  is brought high. Other features include start-up at  $V_{\text{IN}} = 0.9\text{V}$  and an externally programmable soft start time.

### 3.1 Operating Mode

The TC110 is powered by the voltage present on the  $V_{\text{DD}}$  input. The applications circuits of Figure 3-1 and Figure 3-2 show operation in the bootstrapped and non-bootstrapped modes. In bootstrapped mode, the TC110 is powered from the output (start-up voltage is supplied by  $V_{\text{IN}}$  through the inductor and Schottky diode while Q1 is off). In bootstrapped mode, the switching transistor is turned on harder because its gate voltage is higher (due to the boost action of the regulator), resulting in higher output current capacity.

The TC110 is powered from the input supply in the non-bootstrapped mode. In this mode, the supply current to the TC110 is minimized. However, the drive applied to the gate of the switching transistor swings from the input supply level to ground, so the transistor's ON resistance increases at low input voltages. Overall efficiency is increased since supply current is reduced, and less energy is consumed charging and discharging the gate of the MOSFET. While the TC110 is guaranteed to start up at 0.9V the device performs to specifications at 2.0V and higher.

## 3.2 Low Power Shutdown Mode

The TC110 enters a low power shutdown mode when  $\overline{\text{SHDN}}$  is brought low. While in shutdown, the oscillator is disabled and the output switch (internal or external) is shut off. Normal regulator operation resumes when  $\overline{\text{SHDN}}$  is brought high.  $\overline{\text{SHDN}}$  may be tied to the input supply if not used.

**Note:** Because the TC110 uses an external diode, a leakage path between the input voltage and the output node (through the inductor and diode) exists while the regulator is in shutdown. Care must be taken in system design to assure the input supply is isolated from the load during shutdown.

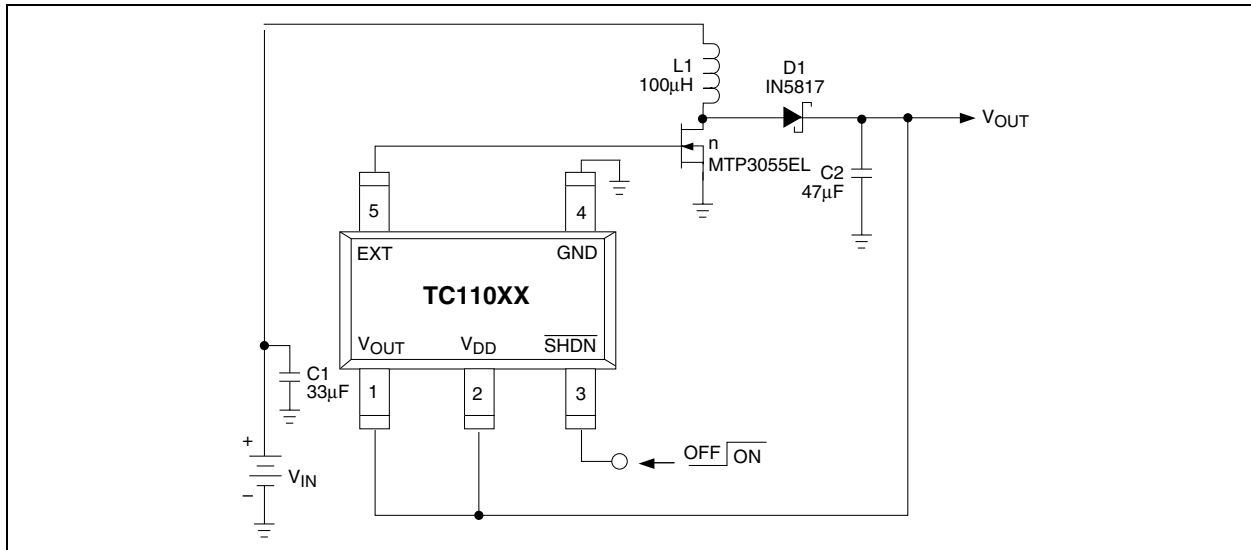

### 3.3 Soft Start

Soft start allows the output voltage to gradually ramp from 0V to rated output value during start-up. This action minimizes (or eliminates) overshoot, and in general, reduces stress on circuit components. Figure 3-3 shows the circuit required to implement soft start (values of 470K and 0.1 $\mu$ F for  $R_{\text{SS}}$  and  $C_{\text{SS}}$ , respectively, are adequate for most applications).

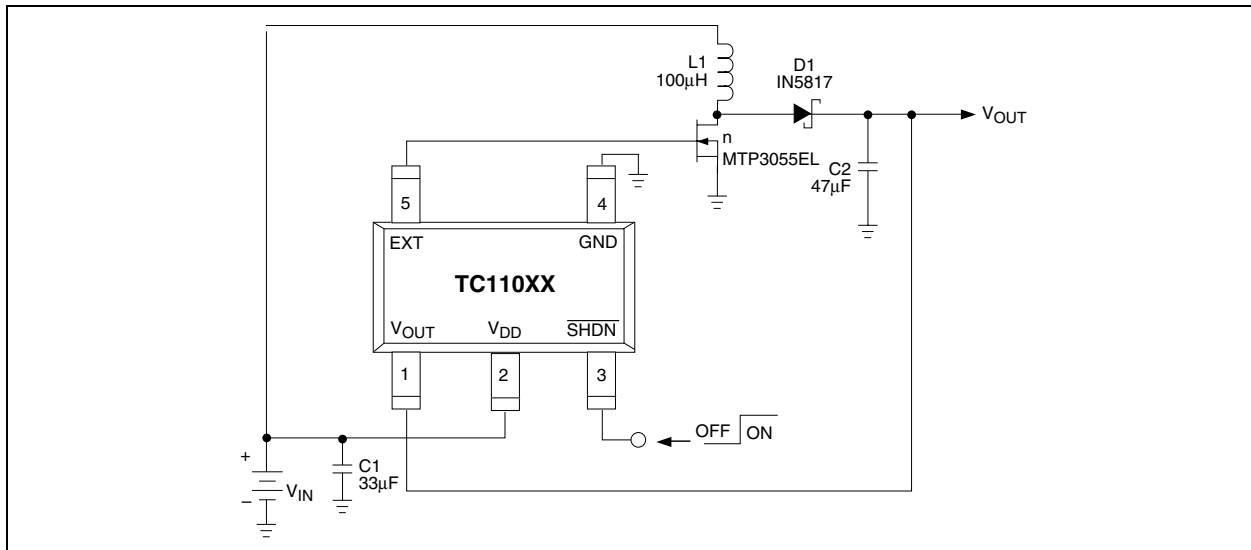

### 3.4 Input Bypass Capacitors

Using an input bypass capacitor reduces peak current transients drawn from the input supply and reduces the switching noise generated by the regulator. The source impedance of the input supply determines the size of the capacitor that should be used.

**FIGURE 3-1: BOOTSTRAPPED OPERATION**

**FIGURE 3-2: NON-BOOTSTRAPPED OPERATION**

**FIGURE 3-3: SOFT START/SHUTDOWN CIRCUIT**

## 3.5 Output Capacitor

The effective series resistance of the output capacitor directly affects the amplitude of the output voltage ripple. (The product of the peak inductor current and the ESR determines output ripple amplitude.) Therefore, a capacitor with the lowest possible ESR should be selected. Smaller capacitors are acceptable for light loads or in applications where ripple is not a concern. The Sprague 595D series of tantalum capacitors are among the smallest of all low ESR surface mount capacitors available. Table 4-1 lists suggested components and suppliers.

## 3.6 Inductor Selection

Selecting the proper inductor value is a trade-off between physical size and power conversion requirements. Lower value inductors cost less, but result in higher ripple current and core losses. They are also more prone to saturate since the coil current ramps faster and could overshoot the desired peak value. This not only reduces efficiency, but could also cause the current rating of the external components to be exceeded. Larger inductor values reduce both ripple current and core losses, but are larger in physical size and tend to increase the start-up time slightly.

A 22μH inductor is recommended for the 300kHz versions and a 47μH inductor is recommended for the 100kHz versions. Inductors with a ferrite core (or equivalent) are also recommended. For highest efficiency, use inductors with a low DC resistance (less than 20 mΩ).

The inductor value directly affects the output ripple voltage. Equation 3-3 is derived as shown below, and can be used to calculate an inductor value, given the required output ripple voltage and output capacitor series resistance:

### EQUATION 3-1:

$$V_{\text{RIPPLE}} \approx \text{ESR}(\text{di})$$

where ESR is the equivalent series resistance of the output filter capacitor, and  $V_{\text{RIPPLE}}$  is in volts.

Expressing di in terms of switch ON resistance and time:

### EQUATION 3-2:

$$V_{\text{RIPPLE}} \approx \frac{\text{ESR} [(V_{\text{IN}} - V_{\text{SW}})t_{\text{ON}}]}{L}$$

Solving for L:

### EQUATION 3-3:

$$L \approx \frac{\text{ESR} [(V_{\text{IN}} - V_{\text{SW}})t_{\text{ON}}]}{V_{\text{RIPPLE}}}$$

Care must be taken to ensure the inductor can handle peak switching currents, which can be several times load currents. Exceeding rated peak current will result in core saturation and loss of inductance. The inductor should be selected to withstand currents greater than  $I_{\text{PK}}$  (Equation 3-10) without saturating.

Calculating the peak inductor current is straightforward. Inductor current consists of an AC (sawtooth) current centered on an average DC current (i.e., input current). Equation 3-6 calculates the average DC current. Note that minimum input voltage and maximum load current values should be used:

### EQUATION 3-4:

$$\text{Input Power} = \frac{\text{Output Power}}{\text{Efficiency}}$$

Re-writing in terms of input and output currents and voltages:

### EQUATION 3-5:

$$(V_{\text{INMIN}})(I_{\text{INMAX}}) = \frac{(V_{\text{OUTMAX}})(I_{\text{OUTMAX}})}{\text{Efficiency}}$$

Solving for input current:

### EQUATION 3-6:

$$I_{\text{INMAX}} = \frac{(V_{\text{OUTMAX}})(I_{\text{OUTMAX}})}{(\text{Efficiency})(V_{\text{INMAX}})}$$

The sawtooth current is centered on the DC current level; swinging equally above and below the DC current calculated in Equation 3-6. The peak inductor current is the sum of the DC current plus half the AC current. Note that minimum input voltage should be used when calculating the AC inductor current (Equation 3-9).

### EQUATION 3-7:

$$V = \frac{L(\text{di})}{dt}$$

### EQUATION 3-8:

$$\text{di} = \frac{V(dt)}{dt}$$

### EQUATION 3-9:

$$\text{di} = \frac{[(V_{\text{INMIN}} - V_{\text{SW}})t_{\text{ON}}]}{L}$$

where:  $V_{\text{SW}} = V_{\text{CESAT}}$  of the switch (note if a CMOS switch is used substitute  $V_{\text{CESAT}}$  for  $r_{\text{DS(on)}} \times I_{\text{IN}}$ )

Combining the DC current calculated in Equation 3-6, with half the peak AC current calculated in Equation 3-9, the peak inductor current is given by:

### EQUATION 3-10:

$$I_{\text{PK}} = I_{\text{INMAX}} + 0.5(\text{di})$$

## 3.7 Output Diode

For best results, use a Schottky diode such as the MA735, 1N5817, MBR0520L or equivalent. Connect the diode between the FB (or SENSE) input as close to the IC as possible. Do not use ordinary rectifier diodes since the higher threshold voltages reduce efficiency.

## 3.8 External Switching Transistor Selection

The EXT output is designed to directly drive an N-channel MOSFET or NPN bipolar transistor. N-channel MOSFETs afford the highest efficiency because they do not draw continuous gate drive current, but are typically more expensive than bipolar transistors. If using an N-channel MOSFET, the gate should be connected directly to the EXT output as shown in Figure 3-1 and Figure 3-1. EXT is a complementary output with a maximum ON resistances of  $43\Omega$  to  $V_{DD}$  when high and  $27\Omega$  to ground when low. Peak currents should be kept below 10mA.

When selecting an N-channel MOSFET, there are three important parameters to consider: total gate charge (Qg); ON resistance ( $r_{DS(on)}$ ) and reverse transfer capacitance (CRSS). Qg is a measure of the total gate capacitance that will ultimately load the EXT output. Too high a Qg can reduce the slew rate of the EXT output sufficiently to grossly lower operating efficiency. Transistors with typical Qg data sheet values of 50nC or less can be used. For example, the Si9410DY has a Qg (typ) of 17nC @  $V_{GS} = 5V$ . This equates to a gate current of:

$$I_{GATEMAX} = f_{MAX} \times Qg = 115kHz \times 17nC = 2mA$$

The two most significant losses in the N-channel MOSFET are switching loss and  $I^2R$  loss. To minimize these, a transistor with low  $r_{DS(on)}$  and low CRSS should be used.

Bipolar NPN transistors can be used, but care must be taken when determining base current drive. Too little current will not fully turn the transistor on, and result in unstable regulator operation and low efficiency. Too high a base drive causes excessive power dissipation in the transistor and increase switching time due to over-saturation. For peak efficiency, make  $R_B$  as large as possible, but still guaranteeing the switching transistor is completely saturated when the minimum value of  $h_{FE}$  is used.

## 3.9 Board Layout Guidelines

As with all inductive switching regulators, the TC110 generates fast switching waveforms which radiate noise. Interconnecting lead lengths should be minimized to keep stray capacitance, trace resistance and radiated noise as low as possible. In addition, the GND pin, input bypass capacitor and output filter capacitor ground leads should be connected to a single point. The input capacitor should be placed as close to power and ground pins of the TC110 as possible.

## 4.0 APPLICATIONS

### 4.1 Circuit Examples

Figure 4-1 shows a TC110 operating as a 100kHz bootstrapped regulator with soft start. This circuit uses an NPN switching transistor (Zetex FZT690B) that has an  $h_{FE}$  of 400 and  $V_{CESAT}$  of 100 mV at  $I_C = 1A$ . Other high beta transistors can be used, but the values of  $R_B$  and  $C_B$  may need adjustment if  $h_{FE}$  is significantly different from that of the FZT690B.

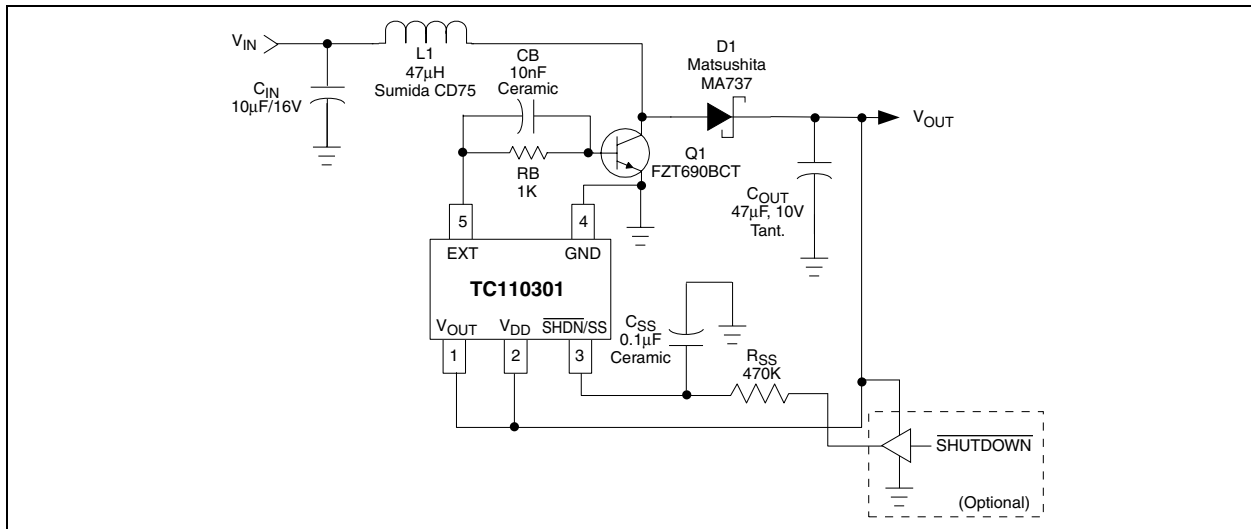

Figure 4-2 and Figure 4-3 both utilize an N-channel switching transistor (Silconix Si9410DY). This transistor is a member of the Littlefoot™ family of small outline MOSFETs. The circuit of Figure 4-2 operates in bootstrapped mode, while the circuit of Figure 4-3 operates in non-bootstrapped mode.
