

FEATURES

AD5544: 16-bit resolution

INL of ± 1 LSB (B Grade)

AD5554: 14-bit resolution

INL of ± 0.5 LSB (B Grade)

2 mA full-scale current $\pm 20\%$, with $V_{REF} = \pm 10$ V

0.9 μ s settling time to $\pm 0.1\%$

12 MHz multiplying bandwidth

Midscale glitch of -1 nV-sec

Midscale or zero-scale reset

4 separate, 4-quadrant multiplying reference inputs

SPI-compatible, 3-wire interface

Double-buffered registers enable

Simultaneous multichannel change

Internal power-on reset

Temperature range: -40°C to $+125^{\circ}\text{C}$

Compact 28-lead SSOP and 32-lead LFCSP

APPLICATIONS

Automatic test equipment

Instrumentation

Digitally controlled calibration

GENERAL DESCRIPTION

The AD5544/AD5554 quad, 16-/14-bit, current output, digital-to-analog converters (DACs) are designed to operate from a 2.7 V to 5.5 V supply range.

The applied external reference input voltage (V_{REFX}) determines the full-scale output current. Integrated feedback resistors (R_{FB}) provide temperature-tracking, full-scale voltage outputs when combined with an external I-to-V precision amplifier.

A double-buffered serial data interface offers high speed, 3-wire, SPI- and microcontroller-compatible inputs using serial data in (SDI), a chip select (\overline{CS}), and clock (CLK) signals. In addition, a serial data out pin (SDO) allows for daisy-chaining when multiple packages are used. A common, level-sensitive, load DAC strobe (LDAC) input allows the simultaneous update of all DAC outputs from previously loaded input registers. Additionally, an internal power-on reset forces the output voltage to 0 at system turn-on. The MSB pin allows system reset assertion (\overline{RS}) to force all registers to zero code when MSB = 0 or to half-scale code when MSB = 1.

FUNCTIONAL BLOCK DIAGRAM

¹AD5544 IS 16-BIT; AD5554 IS 14-BIT

Figure 1.

The AD5544 is packaged in the compact 28-lead SSOP and 32-lead LFCSP. The AD5554 is packaged in the compact 28-lead SSOP.

The EV-AD5544/45SDZ is available for evaluating DAC performance. For more information, see the UG-285 evaluation board user guide.

ABSOLUTE MAXIMUM RATINGS

Table 3.

Parameter	Rating
V_{DD} to GND	-0.3 V, +8 V
V_{SS} to GND	+0.3 V, -7 V
V_{REFX} to GND	-18 V, +18 V
Logic Input and Output to GND	-0.3 V, +8 V
$V(I_{OUTX})$ to GND	-0.3 V, $V_{DD} + 0.3$ V
A_{GNDX} to DGND	-0.3 V, +0.3 V
Input Current to Any Pin Except Supplies	± 50 mA
Package Power Dissipation	$(T_J \text{ max} - T_A)/\theta_{JA}$
Thermal Resistance	θ_{JA}
28-Lead SSOP	100°C/W
32-Lead LFCSP	32.5°C/W
Maximum Junction Temperature (T_J Max)	150°C
Operating Temperature Range	-40°C to +125°C
Storage Temperature Range	-65°C to +150°C
Lead Temperature	
Vapor Phase, 60 Sec	215°C
Infrared, 15 Sec	220°C

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

 2. CONNECT THE EXPOSED PAD TO AGNDx.

Figure 6. LFCSP Pin Configuration

Table 4. Pin Function Descriptions

TSSOP Pin No.	LFCSP Pin No.	Mnemonic	Description
1	29	AGND A	DAC A Analog Ground.
2	30	IOUT A	DAC A Current Output.
3	32	VREF A	DAC A Reference Voltage Input Terminal. Establishes DAC A full-scale output voltage. This pin can be tied to the VDD pin.
4	1	RFB A	DAC A Feedback Resistor Connection. Establish the voltage output for DAC A by connecting this pin to an external amplifier output.
5	2	MSB	MSB Bit. Set this pin during a reset pulse (\overline{RS}) or at system power-on if tied to ground or VDD.
6	3	\overline{RS}	Reset Pin, Active Low Input. Input registers and DAC registers are set to all 0s or half-scale code (0x8000 for the AD5544 and 0x2000 for the AD5554), determined by the voltage on the MSB pin. Register data = 0x0000 when MSB = 0.
7	4	VDD	Positive Power Supply Input. Specified range of operation: 5 V ± 10%.
8	5	\overline{CS}	Chip Select, Active Low Input. Disables shift register loading when high. Transfers serial register data to the input register when $\overline{CS}/\overline{LDAC}$ returns high. Does not affect LDAC operation.
9	6	CLK	Clock Input. Positive edge clocks data into the shift register.
10	7	SDI	Serial Data Input. Input data loads directly into the shift register.
11	8	RFB B	DAC B Feedback Resistor Connection. Establish the voltage output for DAC B by connecting this pin to an external amplifier output.
12	10	VREF B	DAC B Reference Voltage Input Terminal. Establishes DAC B full-scale output voltage. This pin can be tied to the VDD pin.
13	11	IOUT B	DAC B Current Output.
14	12	AGND B	DAC B Analog Ground.
15	13	AGND C	DAC C Analog Ground.
16	14	IOUT C	DAC C Current Output.
17	15	VREF C	DAC C Reference Voltage Input Terminal. Establishes DAC C full-scale output voltage. This pin can be tied to the VDD pin.
18	17	RFB C	DAC C Feedback Resistor Connection. Establish the voltage output for DAC C by connecting this pin to an external amplifier output.
19	9, 16, 25, 26, 31	DNC	Do Not Connect. Leave these pins unconnected.
20	18	SDO	Serial Data Output. Input data loads directly into the shift register. Data appears at SDO at 19 clock pulses for the AD5544 and 17 clock pulses for the AD5554 after input at the SDI pin.
21	19	\overline{LDAC}	Load DAC Register Strobe, Level Sensitive Active Low. Transfers all input register data to DAC registers. Asynchronous active low input. See Table 8 and Table 9 for operation.

TSSOP Pin No.	LFCSP Pin No.	Mnemonic	Description
22	20	A _{GND} F	High Current Analog Force Ground.
23	21	V _{SS}	Negative Bias Power Supply Input. Specified range of operation: -5.5 V to +0.3 V.
24	22	DGND	Digital Ground Pin.
25	23	R _{FB} D	DAC D Feedback Resistor Connection. Establish the voltage output for DAC D by connecting this pin to an external amplifier output.
26	24	V _{REF} D	DAC D Reference Voltage Input Terminal. Establishes DAC D full-scale output voltage. This pin can be tied to the V _{DD} pin.
27	27	I _{OUT} D	DAC D Current Output.
28	28	A _{GND} D	DAC D Analog Ground.
N/A ¹		EPAD	Connect the exposed pad to AGNDx.

¹ N/A means not applicable.

Figure 19. AD5544/AD5554 Power Supply Current vs. Logic Input Voltage

THEORY OF OPERATION

The [AD5544](#) and the [AD5554](#) contain four 16-bit and 14-bit, current output DACs, respectively. Each DAC has its own independent multiplying reference input. Both the [AD5544](#) and the [AD5554](#) use a 3-wire, SPI-compatible serial data interface, with a configurable asynchronous \overline{RS} pin for half-scale (MSB = 1) or zero-scale (MSB = 0) preset. In addition, an \overline{LDAC} strobe enables 4-channel, simultaneous updates for hardware synchronized output voltage changes.

DIGITAL-TO-ANALOG CONVERTER (DAC)

Each part contains four current-steering R-R ladder DACs. Figure 20 shows a typical equivalent DAC. Each DAC contains a matching feedback resistor for use with an external I-to-V converter amplifier. The R_{FBX} pin connects to the output of the external amplifier. The I_{OUTX} terminal connects to the inverting input of the external amplifier. The A_{GNDX} pin should be Kelvin-connected to the load point, requiring full 16-bit accuracy. These DACs are designed to operate with both negative and positive reference voltage.

The V_{DD} power pin is used only by the logic to drive the DAC switches on and off. Note that a matching switch is used in series with the internal 5 k Ω feedback resistor. If users attempt to measure the value of R_{FB} , power must be applied to V_{DD} to achieve continuity. An additional V_{SS} bias pin is used to guard the substrate during high temperature applications, minimizing zero-scale leakage currents that double every 10°C. The DAC output voltage is determined by V_{REF} and the digital data (D) in the following equations:

$$V_{OUT} = -V_{REF} \times \frac{D}{65,536} \quad (\text{for the AD5544}) \quad (1)$$

$$V_{OUT} = -V_{REF} \times \frac{D}{16,384} \quad (\text{for the AD5554}) \quad (2)$$

Note that the output polarity is opposite the V_{REF} polarity for dc reference voltages.

DIGITAL INTERFACE CONNECTIONS OMITTED FOR CLARITY. SWITCHES S1 AND S2 ARE CLOSED, AND V_{DD} MUST BE POWERED.

Figure 20. Typical Equivalent DAC Channel

These DACs are also designed to accommodate ac reference input signals. Both the [AD5544](#) and the [AD5554](#) accommodate input reference voltages in the range of -15 V to $+15\text{ V}$. The reference voltage inputs exhibit a constant nominal input resistance of $5\text{ k}\Omega \pm 30\%$. On the other hand, the I_{OUTA} , I_{OUTB} , I_{OUTC} , and I_{OUTD} DAC outputs are code dependent and produce various output resistances and capacitances. The choice of external amplifier should take into account the variation in impedance generated by the [AD5544/AD5554](#) on the inverting input node of the amplifier. The feedback resistance, in parallel with the DAC ladder resistance, dominates output voltage noise. For multiplying mode applications, an external feedback compensation capacitor, C_{FB} , may be needed to provide a critically damped output response for step changes in reference input voltages. Figure 21 shows the gain vs. frequency performance at various attenuation settings using a 23 pF external feedback capacitor connected across the I_{OUTX} and R_{FBX} terminals for the [AD5544](#) and the [AD5554](#), respectively. To maintain good analog performance, power supply bypassing of 0.01 μF , in parallel with 1 μF , is recommended. Under these conditions, a clean power supply with low ripple voltage capability should be used. Switching power supplies is usually not suitable for this application due to the higher ripple voltage and PSS frequency-dependent characteristics. It is best to derive the supply of the [AD5544/AD5554](#) from system analog supply voltages. Do not use the digital supply (see Figure 22).

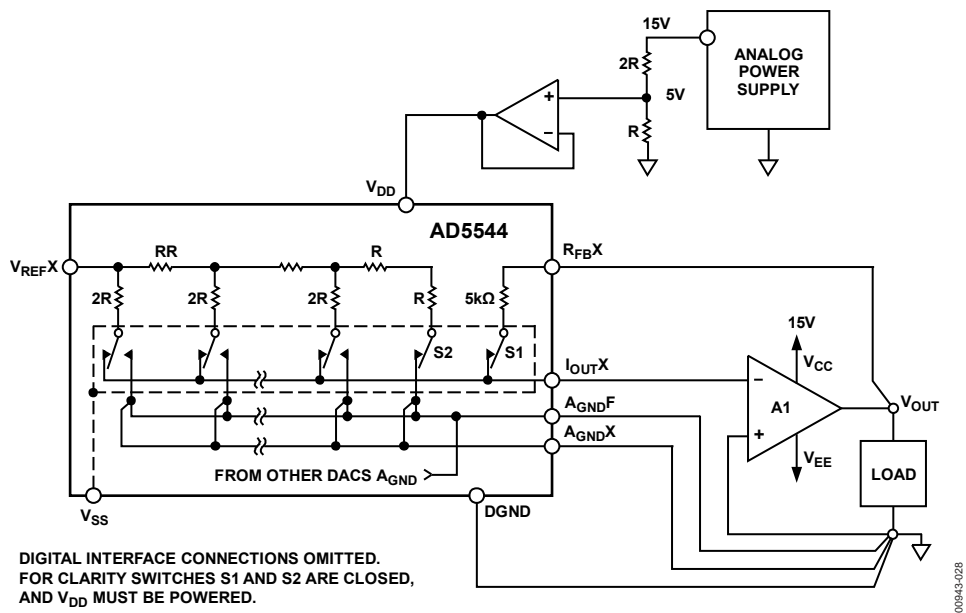

Figure 22. Recommended Kelvin-Sensed Hookup

00043-028

SERIAL DATA INTERFACE

The AD5544/AD5554 use a 3-wire ($\overline{\text{CS}}$, SDI, CLK), SPI-compatible serial data interface. Serial data of the AD5544/AD5554 is clocked into the serial input register in an 18-bit and 16-bit data-word format, respectively. The MSB bits are loaded first. Table 5 defines the 18 data-word bits for the AD5544, and Table 6 defines the 16 data-word bits for the AD5554. Data is placed on the SDI pin and clocked into the register on the positive clock edge of CLK, subject to the data setup and data hold time requirements specified in the interface timing specifications (see Table 1 and Table 2).

Data can be clocked in only while the $\overline{\text{CS}}$ chip select pin is active low. For the AD5544, only the last 18 bits clocked into the serial register are interrogated when the $\overline{\text{CS}}$ pin returns to the logic high state; extra data bits are ignored. For the AD5554, only the last 16 bits clocked into the serial register are interrogated when the $\overline{\text{CS}}$ pin returns to the logic high state. Because most microcontrollers output serial data in 8-bit bytes, three right justified data bytes can be written to the AD5544. Keeping the $\overline{\text{CS}}$ line low between the first, second, and third byte transfers results in a successful serial register update.

Similarly, two right justified data bytes can be written to the AD5554. Keeping the $\overline{\text{CS}}$ line low between the first and second byte transfer results in a successful serial register update.

When the data is properly aligned in the shift register, the positive edge of the $\overline{\text{CS}}$ initiates the transfer of new data to the target DAC register, determined by the decoding of Address Bit A1 and Address Bit A0. For the AD5544, Table 5, Table 7, Table 8, and Figure 3 define the characteristics of the software serial interface.

For the AD5554, Table 6, Table 7, Table 9, and Figure 4 define the characteristics of the software serial interface. Figure 23 and Figure 24 show the equivalent logic interface for the key digital control pins for the AD5544. The AD5554 has a similar configuration, except that it has 14 data bits. Two additional pins, $\overline{\text{RS}}$ and MSB, provide hardware control over the preset function and DAC register loading. If these functions are not needed, the $\overline{\text{RS}}$ pin can be tied to logic high. The asynchronous input $\overline{\text{RS}}$ pin forces all input and the DAC registers to either the zero-code state (MSB = 0) or the half-scale state (MSB = 1).

Table 5. AD5544 Serial Input Register Data Format (Data Is Loaded in the MSB-First Format)¹

MSB															LSB		
B17	B16	B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0
A1	A0	D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0

¹ Only the last 18 bits of data clocked into the serial register (address + data) are inspected when the positive edge of the $\overline{\text{CS}}$ line returns to logic high. At this point, an internally generated load strobe transfers the serial register data contents (Bit D15 to Bit D0) to the decoded DAC input register address determined by Bit A1 and Bit A0. Any extra bits clocked into the AD5544 shift register are ignored; only the last 18 bits clocked in are used. If double-buffered data is not needed, the $\overline{\text{LDAC}}$ pin can be tied logic low to disable the DAC registers.

Table 6. AD5554 Serial Input Register Data Format (Data Is Loaded in the MSB-First Format)¹

MSB															LSB
B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0
A1	A0	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0

¹ Only the last 16 bits of data clocked into the serial register (address + data) are inspected when the positive edge of the $\overline{\text{CS}}$ line returns to logic high. At this point, an internally generated load strobe transfers the serial register data contents (Bit D13 to Bit D0) to the decoded DAC input register address determined by Bit A1 and Bit A0. Any extra bits clocked into the AD5554 shift register are ignored; only the last 16 bits clocked in are used. If double-buffered data is not needed, the $\overline{\text{LDAC}}$ pin can be tied logic low to disable the DAC registers.

ESD PROTECTION CIRCUITS

All logic input pins contain back-biased ESD protection Zener diodes that are connected to ground (DGND) and V_{DD} , as shown in Figure 25.

Figure 25. Equivalent ESD Protection Circuits

00943-031

POWER-ON RESET

When the V_{DD} power supply is turned on, an internal reset strobe forces all the input and DAC registers to the zero-code state or half-scale state, depending on the MSB pin voltage. The V_{DD} power supply should have a smooth positive ramp without drooping to have consistent results, especially in the region of $V_{DD} = 1.5\text{ V}$ to 2.3 V . The V_{SS} supply has no effect on the power-on reset performance. The DAC register data stays at a zero-scale or half-scale setting until a valid serial register data load takes place.

POWER SUPPLY SEQUENCE

As standard practice, it is recommended that V_{DD} , V_{SS} , and ground be powered up prior to any reference. The ideal power-up sequence is as follows: A_{GNDx} , DGND, V_{DD} , V_{SS} , V_{REFx} , and the digital inputs. A noncompliance power-up sequence may elevate the reference current, but the devices resume normal operation once V_{DD} and V_{SS} are powered up.

LAYOUT AND POWER SUPPLY BYPASSING

It is good practice to employ a compact, minimum lead length layout design. The leads to the input should be as direct as possible with a minimum conductor length. Ground paths should have low resistance and low inductance.

Similarly, it is good practice to bypass the power supplies with quality capacitors for optimum stability. Supply leads to the device should be bypassed with 0.01 μF to 0.1 μF disc or chip ceramic capacitors. Low ESR 1 μF to 10 μF tantalum or electrolytic capacitors should also be applied at V_{DD} to minimize any transient disturbance and filter any low frequency ripple (see Figure 26). Users should not apply switching regulators for V_{DD} due to the power supply rejection ratio (PSRR) degradation over frequency.

Figure 26. Power Supply Bypassing and Grounding Connection

GROUNDING

The DGND and AGNDX pins of the AD5544/AD5554 serve as digital and analog ground references. To minimize the digital ground bounce, the DGND terminal should be joined remotely at a single point to the analog ground plane (see Figure 26).

APPLICATIONS INFORMATION

The AD5544/AD5554 are, inherently, two-quadrant multiplying DACs. That is, they can be easily set up for unipolar output operation. The full-scale output polarity is the inverse of the reference input voltage.

In some applications, it may be necessary to generate the full four-quadrant multiplying capability or a bipolar output swing. This is easily accomplished using an additional external amplifier (A2) configured as a summing amplifier (see Figure 27).

Figure 27. Four-Quadrant Multiplying Application Circuit

In this circuit, the first and second amplifiers (A1 and A2) provide a total gain of 2, which increases the output voltage span to 20 V. Biasing the external amplifier with a 10 V offset from the reference voltage results in a full four-quadrant multiplying circuit. The transfer equation of this circuit shows that both negative and positive output voltages are created as the input data (D) is incremented from code zero ($V_{OUT} = -10$ V) to midscale ($V_{OUT} = 0$ V) to full scale ($V_{OUT} = 10$ V).

$$V_{OUT} \left(\frac{D}{32,768} - 1 \right) \times -V_{REF} \text{ (for the AD5544)} \quad (3)$$

$$V_{OUT} \left(\frac{D}{8192} - 1 \right) \times -V_{REF} \text{ (for the AD5554)} \quad (4)$$

REFERENCE SELECTION

When selecting a reference for use with the AD55xx series of current output DACs, pay attention to the output voltage, temperature coefficient specification of the reference. Choosing a precision reference with a low output temperature coefficient minimizes error sources. Table 10 lists some of the references available from Analog Devices, Inc., that are suitable for use with this range of current output DACs.

AMPLIFIER SELECTION

The primary requirement for the current-steering mode is an amplifier with low input bias currents and low input offset voltage. Because of the code-dependent output resistance of the DAC, the input offset voltage of an op amp is multiplied by the variable gain of the circuit. A change in this noise gain between two adjacent digital fractions produces a step change in the output voltage due to the amplifier's input offset voltage. This output voltage change is superimposed upon the desired change in output between the two codes and gives rise to a differential linearity error, which, if large enough, can cause the DAC to be nonmonotonic.

The input bias current of an op amp also generates an offset at the voltage output because of the bias current flowing in the feedback resistor, R_{FB} .

Common-mode rejection of the op amp is important in voltage-switching circuits because it produces a code-dependent error at the voltage output of the circuit.

Provided that the DAC switches are driven from true wideband, low impedance sources (V_{IN} and AGND), they settle quickly. Consequently, the slew rate and settling time of a voltage-switching DAC circuit is determined largely by the output op amp. To obtain minimum settling time in this configuration, minimize capacitance at the V_{REF} node (the voltage output node in this application) of the DAC. This is done by using low input capacitance buffer amplifiers and careful board design.

Analog Devices offers a wide range of amplifiers for both precision dc and ac applications, as listed in Table 11 and Table 12.
