

FEATURES

Offset voltage:

- 25 μV maximum at 25°C (B grade, 8-lead SOIC, single/ dual)
- 50 μV maximum at 25°C (A grade, 8-lead SOIC, single/ dual)
- 50 μV maximum at 25°C (A grade, 14-lead SOIC, quad)

Offset voltage drift:

- 0.25 $\mu\text{V}/^\circ\text{C}$ maximum (B grade, 8-lead SOIC, single/dual)
- 0.55 $\mu\text{V}/^\circ\text{C}$ maximum (A grade, 8-lead SOIC, single/dual)
- 0.75 $\mu\text{V}/^\circ\text{C}$ maximum (A grade, 14-lead SOIC, quad)

MSL1 rated

- Low input bias current: 1 nA maximum at $T_A = 25^\circ\text{C}$
- Low voltage noise density: 6.9 nV/ $\sqrt{\text{Hz}}$ typical at $f = 1000 \text{ Hz}$
- CMRR, PSRR, and $A_V > 120 \text{ dB}$ minimum
- Low supply current: 400 μA per amplifier typical
- Wide gain bandwidth product: 3.9 MHz at $\pm 5 \text{ V}$

Dual-supply operation:

- Specified at $\pm 5 \text{ V}$ to $\pm 15 \text{ V}$
- Operates at $\pm 2.5 \text{ V}$ to $\pm 15 \text{ V}$

Unity gain stable

No phase reversal

Long-term offset voltage drift (10,000 hours): 0.5 μV typical

Temperature hysteresis: 1 μV typical

APPLICATIONS

- Process control front-end amplifiers
- Optical network control circuits
- Instrumentation
- Precision sensors and controls
- Precision filters

GENERAL DESCRIPTION

The single ADA4077-1, dual ADA4077-2, and quad ADA4077-4 amplifiers feature extremely low offset voltage and drift, and low input bias current, noise, and power consumption. Outputs are stable with capacitive loads of more than 1000 pF with no external compensation.

Applications for this amplifier include sensor signal conditioning (such as thermocouples, resistance temperature detectors (RTDs), strain gages), process control front-end amplifiers, and precision diode power measurement in optical and wireless transmission systems. The ADA4077-1/ADA4077-2/ADA4077-4 are useful in line powered and portable instrumentation, precision filters, and voltage or current measurement and level setting.

Unlike other amplifiers, the ADA4077-1/ADA4077-2/ADA4077-4 have an MSL1 rating that is compliant with the most stringent of assembly processes, and they are specified over the extended industrial temperature range from -40°C to $+125^\circ\text{C}$ for the most demanding operating environments.

ABSOLUTE MAXIMUM RATINGS

Table 4.

Parameter	Rating
Supply Voltage	36 V
Input Voltage	$\pm V_{SY}$
Input Current ¹	± 10 mA
Differential Input Voltage	$\pm V_{SY}$
Output Short-Circuit Duration to GND	Indefinite
Storage Temperature Range	-65°C to +150°C
Operating Temperature Range	-40°C to +125°C
Junction Temperature Range	-65°C to +150°C
Maximum Reflow Temperature (MSL1 Rating) ²	260°C
Lead Temperature, Soldering (10 sec)	300°C
Electrostatic Discharge (ESD)	
Human Body Model (HBM) ³	6 kV
Field Induced Charge Device Model (FICDM) ⁴	1.25 kV

¹ The input pins have clamp diodes to the power supply pins and to each other. Limit the input current to 10 mA or less whenever input signals exceed the power supply rail by 0.3 V.

² IPC/JEDEC J-STD-020 applicable standard.

³ ESDA/JEDEC JS-001-2011 applicable standard.

⁴ JESD22-C101 (ESD FICDM standard of JEDEC) applicable standard.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

THERMAL RESISTANCE

θ_{JA} is specified for the worst case conditions, that is, a device soldered in a circuit board for surface-mount packages.

Table 5. Thermal Resistance

Package Type	θ_{JA}	θ_{JC}	Unit
8-Lead MSOP	190	44	°C/W
8-Lead SOIC	158	43	°C/W
14-Lead TSSOP	240	43	°C/W
14-Lead SOIC	115	36	°C/W

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

THEORY OF OPERATION

The [ADA4077-1/ADA4077-2/ADA4077-4](#) are the sixth generation of the Analog Devices, Inc., industry-standard [OP07](#) amplifier family. The [ADA4077-1/ADA4077-2/ADA4077-4](#) are high precision, low noise operational amplifiers with a combination of extremely low offset voltage and very low input bias currents. Unlike JFET amplifiers, the low bias and offset currents are relatively insensitive to ambient temperatures, even up to 125°C.

The Analog Devices proprietary process technology and linear design expertise have produced high voltage amplifiers with superior performance to the [OP07/OP77/OP177/OP1177](#) in tiny, 8-lead SOIC and 8-lead MSOP packages ([ADA4077-1](#) and [ADA4077-2](#)) and 14-lead TSSOP and 14-lead SOIC packages ([ADA4077-4](#)). Despite their small size, the [ADA4077-1/ADA4077-2/ADA4077-4](#) offer numerous improvements, including low wideband noise, wide bandwidth, lower offset and offset drift, lower input bias current, and complete freedom from phase inversion.

The [ADA4077-1/ADA4077-2/ADA4077-4](#) have an operating temperature range of -40°C to $+125^{\circ}\text{C}$ with an MSL1 rating, which is as wide as any similar device in a plastic surface-mount package. This MSL1 rating is increasingly important as printed circuit board (PCB) and overall system sizes continue to shrink, causing internal system temperatures to rise.

In the [ADA4077-1/ADA4077-2/ADA4077-4](#), the power consumption is reduced by a factor of four compared to the [OP177](#), and the bandwidth and slew rate are both increased by a factor of six. The low power dissipation and very stable performance vs. temperature also reduce warmup drift errors to insignificant levels.

Inputs are protected internally from overvoltage conditions referenced to either supply rail. Like any high performance amplifier, maximum performance is achieved by following appropriate circuit and PCB guidelines.

APPLICATIONS INFORMATION

OUTPUT PHASE REVERSAL

Phase reversal is defined as a change of polarity in the amplifier transfer function. Many operational amplifiers exhibit phase reversal when the voltage applied to the input is greater than the maximum common-mode voltage. In some instances, this phase reversal can cause permanent damage to the amplifier. In feedback loops, it can result in system lockups or equipment damage. The [ADA4077-1/ADA4077-2/ADA4077-4](#) are immune to phase reversal problems even at input voltages beyond the power supply settings.

Figure 70. No Phase Reversal

LOW POWER LINEARIZED RTD

A common application for a single element varying bridge is an RTD thermometer amplifier, as shown in Figure 71. The excitation is delivered to the bridge by a 2.5 V reference applied at the top of the bridge.

RTDs can have a thermal resistance as high as $0.5^{\circ}\text{C}/\text{mW}$ to $0.8^{\circ}\text{C}/\text{mW}$. To minimize errors due to resistor drift, keep the current low through each leg of the bridge. In this circuit, the amplifier supply current flows through the bridge. However, at a maximum supply current of $500\ \mu\text{A}$ for the [ADA4077-2](#), the RTD dissipates less than $0.1\ \text{mW}$ of power, even at the highest resistance. Therefore, errors due to power dissipation in the bridge are kept under 0.1°C .

Calibration of the bridge is made at the minimum value of the temperature to be measured by adjusting R_p until the output is zero.

To calibrate the output span, set the full-scale and linearity potentiometers to midpoint, and apply a 500°C temperature to the sensor, or substitute the equivalent 500°C RTD resistance.

Adjust the full-scale potentiometer for a 5 V output. Finally, apply 250°C or the equivalent RTD resistance, and adjust the linearity potentiometer for a 2.5 V output. The circuit achieves higher than $\pm 0.5^{\circ}\text{C}$ accuracy after adjustment.

Figure 71. Low Power Linearized RTD Circuit

PROPER BOARD LAYOUT

The [ADA4077-1/ADA4077-2/ADA4077-4](#) are high precision devices. To ensure optimum performance at the PCB level, care must be taken in the design of the board layout.

To avoid leakage currents, maintain a clean and moisture free board surface. Coating the surface creates a barrier to moisture accumulation, and reduces parasitic resistance on the board.

Keeping supply traces short and properly bypassing the power supplies minimizes the power supply disturbances caused by the output current variation, such as when driving an ac signal into a heavy load. Connect bypass capacitors as closely as possible to the device supply pins. Stray capacitances are a concern at the outputs and the inputs of the amplifier. It is recommended that the signal traces be kept at least 5 mm from supply lines to minimize coupling.

A variation in temperature across the PCB can cause a mismatch in the Seebeck voltages at solder joints and other points where dissimilar metals are in contact, resulting in thermal voltage errors. To minimize these thermocouple effects, orient resistors so that heat sources warm both ends equally. Ensure, where possible, that input signal paths contain matching numbers and types of components, to match the number and type of thermocouple junctions. For example, dummy components such as zero value resistors can be used to match real resistors in the opposite input path. Place matching components in close proximity to each other, and orient them in the same manner. Ensure that leads are of equal length so that thermal conduction is in equilibrium. Keep heat sources on the PCB as far away from amplifier input circuitry as is practical.

The use of a ground plane is highly recommended. A ground plane reduces electromagnetic interference (EMI) noise and maintains a constant temperature across the circuit board.

LONG-TERM DRIFT

The stability of a precision signal path over its lifetime or between calibration procedures is dependent on the long-term stability of the analog components in the path, such as op amps, references, and data converters. To help system designers predict the long-term drift of circuits that use the ADA4077-1/ADA4077-2/ADA4077-4, Analog Devices measured the offset voltage of multiple units for 10,000 hours (more than 13 months) using a high precision measurement system, including an ultrastable oil bath. To replicate real-world system performance, the devices under test (DUTs) were soldered onto an FR4 PCB using a standard reflow profile (as defined in the JEDEC J-STD-020D standard), as opposed to testing them in sockets. This manner of testing is important because expansion and contraction of the PCB can apply stress to the integrated circuit (IC) package and contribute to shifts in the offset voltage.

The ADA4077-1/ADA4077-2/ADA4077-4 have extremely low long-term drift (LTD). Figure 72 shows the LTD of the ADA4077-1 (SOIC package). The red, blue, and green traces show sample units. Note that the mean drift over 10,000 hours is less than 0.5 μV , or less than 2% of their maximum specified offset voltage of 25 μV at room temperature.

Figure 72. Measured Long-Term Drift of the ADA4077-1/ADA4077-2/ADA4077-4 Offset Voltage over 10,000 Hours

TEMPERATURE HYSTERESIS

In addition to stability over time as described in the Long-Term Drift section, it is useful to know the temperature hysteresis, that is, the stability vs. cycling of temperature. Hysteresis is an important parameter because it tells the system designer how closely the signal returns to its starting amplitude after the ambient temperature changes and subsequent return to room temperature. Figure 73 shows the change in input offset voltage as the temperature cycles three times from room temperature to 125°C to -40°C and back to room temperature. The dotted line is an initial preconditioning cycle to eliminate the original temperature-induced offset shift from exposure to production solder reflow temperatures. In the three full cycles, the offset hysteresis is typically only 1 μV , or 1.5% of its 65 μV maximum offset voltage over the full operating temperature range. The histogram in Figure 74 shows that the hysteresis is larger when the device is cycled through only a half cycle, from room temperature to 125°C and back to room temperature.
