

FEATURES

Up to 533 MHz high performance Blackfin processor
 Two 16-bit MACs, two 40-bit ALUs, four 8-bit video ALUs, 40-bit shifter
 RISC-like register and instruction model for ease of programming and compiler friendly support
 Advanced debug, trace, and performance monitoring
 Wide range of operating voltages (see [Operating Conditions on Page 23](#))
 Programmable on-chip voltage regulator
 316-ball Pb-free CSP_BGA package

MEMORY

Up to 148K bytes of on-chip memory (see [Table 1 on Page 3](#))
 Optional 8M bit parallel flash with boot option
 Memory management unit providing memory protection
 External memory controller with glueless support for SDRAM, SRAM, flash, and ROM
 Flexible memory booting options from SPI and external memory

PERIPHERALS

Parallel peripheral interface (PPI) supporting ITU-R 656 video data formats
 4 dual-channel, full-duplex synchronous serial ports, supporting 16 stereo I²S channels
 2 DMA controllers supporting 26 peripheral DMAs
 4 memory-to-memory DMAs
 Controller area network (CAN) 2.0B controller
 3 SPI-compatible ports
 Three 32-bit timer/counters with PWM support
 3 UARTs with support for IrDA
 2 TWI controllers compatible with I²C industry standard
 Up to 54 general-purpose I/O pins (GPIO)
 Real-time clock, watchdog timer, and 32-bit core timer
 On-chip PLL capable of frequency multiplication
 Debug/JTAG interface

Added Timer Clock Timing	44
Added missing timing specifications to Table 39 in Timer Cycle Timing	45

GENERAL DESCRIPTION

The ADSP-BF538/ADSP-BF538F processors are members of the Blackfin® family of products, incorporating the Analog Devices, Inc./Intel Micro Signal Architecture (MSA). Blackfin processors combine a dual-MAC state-of-the-art signal processing engine, the advantages of a clean, orthogonal RISC-like microprocessor instruction set, and single-instruction, multiple-data (SIMD) multimedia capabilities into a single instruction set architecture.

The ADSP-BF538/ADSP-BF538F processors are completely code compatible with other Blackfin processors, differing only with respect to performance, peripherals, and on-chip memory. Specific performance, peripherals, and memory configurations are shown in [Table 1](#).

Table 1. Processor Features

Feature	ADSP-BF538	ADSP-BF538F8
SPORTs	4	4

Maximum Frequency	533 MHz 1066 MMACS	533 MHz 1066 MMACS
Package Option	BC-316	BC-316

By integrating a rich set of industry-leading system peripherals and memory, Blackfin processors are the platform of choice for next generation applications that require RISC-like programmability, multimedia support, and leading edge signal processing in one integrated package.

LOW POWER ARCHITECTURE

Blackfin processors provide world class power management and performance. They are designed using a low power and low voltage methodology and feature dynamic power management, which is the ability to vary both the voltage and frequency of operation to significantly lower overall power consumption. Varying the voltage and frequency can result in a substantial reduction in power consumption, compared with just varying the frequency of operation. This translates into longer battery life and lower heat dissipation.

SYSTEM INTEGRATION

The ADSP-BF538/ADSP-BF538F processors are highly integrated system-on-a-chip solutions for the next generation of consumer and industrial applications including audio and video signal processing. By combining advanced memory configurations, such as on-chip flash memory, industry-standard interfaces, and a high performance signal processing core, cost-effective solutions can be quickly developed, without the need for costly external components. The system peripherals include three UART ports, three SPI ports, four serial ports (SPORTs), one CAN interface, two 2-wire interfaces (TWI), four general-purpose timers (three with PWM capability), a real-time clock, a watchdog timer, a parallel peripheral interface (PPI), and general-purpose I/O pins.

ADSP-BF538/ADSP-BF538F PROCESSOR PERIPHERALS

The ADSP-BF538/ADSP-BF538F processors contain a rich set of peripherals connected to the core via several high bandwidth buses, providing flexibility in system configuration as well as excellent overall system performance (see the block diagram [1](#)). The general-purpose peripherals include functions such as UART, timers with PWM (pulse-width modulation) and pulse measurement capability, general-purpose I/O pins, a real-time clock, and a watchdog timer. This set of functions satisfies a wide variety of typical system support needs and is augmented by the system expansion capabilities of the device. In addition to these general-purpose peripherals, the processors contain high speed serial and parallel ports for interfacing to a variety of audio, video, and modem codec functions. A CAN 2.0B controller is provided for automotive and industrial control networks. An interrupt controller manages interrupts from the on-chip peripherals or from external sources. Power management control functions tailor the performance and power characteristics of the processors and system to many application scenarios.

All of the peripherals, except for general-purpose I/O, CAN, TWI, real-time clock, and timers, are supported by a flexible DMA structure. There are also four separate memory DMA channels dedicated to data transfers between the processor's various memory spaces, including external SDRAM and asynchronous memory. Multiple on-chip buses running at up to 133 MHz provide enough bandwidth to keep the processor core running with activity on all of the on-chip and external peripherals.

The ADSP-BF538/ADSP-BF538F processors include an on-chip voltage regulator in support of the processor's dynamic power management capability. The voltage regulator provides a range of core voltage levels from V_{DDEXT} . The voltage regulator can be bypassed as needed.

ADSP-BF538/ADSP-BF538F

BLACKFIN PROCESSOR CORE

As shown in Figure 2 on Page 4, the Blackfin processor core contains two 16-bit multipliers, two 40-bit accumulators, two 40-bit ALUs, four video ALUs, and a 40-bit shifter. The computation units process 8-bit, 16-bit, or 32-bit data from the register file.

The compute register file contains eight 32-bit registers. When performing compute operations on 16-bit operand data, the register file operates as 16 independent 16-bit registers. All operands for compute operations come from the multiplexed register file and instruction constant fields.

Each MAC can perform a 16-bit by 16-bit multiply in each cycle, accumulating the results into the 40-bit accumulators. Signed and unsigned formats, rounding, and saturation are supported.

The ALUs perform a traditional set of arithmetic and logical operations on 16-bit or 32-bit data. In addition, many special instructions are included to accelerate various signal processing tasks. These include bit operations such as field extract and population count, modulo 2^{32} multiply, divide primitives, saturation and rounding, and sign/exponent detection. The set of video

instructions includes byte alignment and packing operations, 16-bit and 8-bit adds with clipping, 8-bit average operations, and 8-bit subtract/absolute value/accumulate (SAA) operations. The compare/select and vector search instructions are also provided.

For certain instructions, two 16-bit ALU operations can be performed simultaneously on register pairs (a 16-bit high half and 16-bit low half of a compute register). Quad 16-bit operations are possible using the second ALU.

The 40-bit shifter can perform shifts and rotates and is used to support normalization, field extract, and field deposit instructions.

The program sequencer controls the flow of instruction execution, including instruction alignment and decoding. For program flow control, the sequencer supports PC relative and indirect conditional jumps (with static branch prediction), and subroutine calls. Hardware is provided to support zero overhead looping. The architecture is fully interlocked, meaning that the programmer need not manage the pipeline when executing instructions with data dependencies.

Figure 2. Blackfin Processor Core

The address arithmetic unit provides two addresses for simultaneous dual fetches from memory. It contains a multiported register file consisting of four sets of 32-bit index, modify, length, and base registers (for circular buffering), and eight additional 32-bit pointer registers (for C style indexed stack manipulation).

Blackfin processors support a modified Harvard architecture in combination with a hierarchical memory structure. Level 1 (L1) memories are those that typically operate at the full processor speed with little or no latency. At the L1 level, the instruction memory holds instructions only. The two data memories hold data, and a dedicated scratchpad data memory stores stack and local variable information.

In addition, multiple L1 memory blocks are provided, offering a configurable mix of SRAM and cache. The memory management unit (MMU) provides memory protection for individual tasks that may be operating on the core and can protect system registers from unintended access.

The architecture provides three modes of operation: user mode, supervisor mode, and emulation mode. User mode has restricted access to certain system resources, thus providing a protected software environment, while supervisor mode has unrestricted access to the system and core resources.

The Blackfin processor instruction set has been optimized so that 16-bit opcodes represent the most frequently used instructions, resulting in excellent compiled code density. Complex DSP instructions are encoded into 32-bit opcodes, representing fully featured multifunction instructions. Blackfin processors support a limited multi-issue capability, where a 32-bit instruction can be issued in parallel with two 16-bit instructions, allowing the programmer to use many of the core resources in a single instruction cycle.

The Blackfin processor assembly language uses an algebraic syntax for ease of coding and readability. The architecture has been optimized for use in conjunction with the C/C++ compiler, resulting in fast and efficient software implementations.

MEMORY ARCHITECTURE

The ADSP-BF538/ADSP-BF538F processors view memory as a single unified 4G byte address space, using 32-bit addresses. All resources, including internal memory, external memory, and I/O control registers, occupy separate sections of this common address space. The memory portions of this address space are arranged in a hierarchical structure to provide a good cost/performance balance of some very fast, low latency on-chip memory as cache or SRAM, and larger, lower cost and performance off-chip memory systems. See [Figure 3](#).

The L1 memory system is the primary highest performance memory available to the Blackfin processor. The off-chip memory system, accessed through the External Bus Interface Unit (EBIU), provides expansion with SDRAM, flash memory, and SRAM, optionally accessing up to 132M bytes of physical memory.

Figure 3. ADSP-BF538/ADSP-BF538F Internal/External Memory Map

The memory DMA controllers provide high bandwidth data movement capability. They can perform block transfers of code or data between the internal memory and the external memory spaces.

Internal (On-Chip) Memory

The ADSP-BF538/ADSP-BF538F processors have three blocks of on-chip memory, providing high bandwidth access to the core.

The first is the L1 instruction memory, consisting of 80K bytes SRAM, of which 16K bytes can be configured as a four way set-associative cache. This memory is accessed at full processor speed.

The second on-chip memory block is the L1 data memory, consisting of two banks of up to 32K bytes each. Each memory bank is configurable, offering both two-way set-associative cache and SRAM functionality. This memory block is accessed at full processor speed.

The third memory block is a 4K byte scratchpad SRAM, which runs at the same speed as the L1 memories, but is only accessible as data SRAM and cannot be configured as cache memory.

ADSP-BF538/ADSP-BF538F

External (Off-Chip) Memory

External memory is accessed via the external bus interface unit (EBIU). This 16-bit interface provides a glueless connection to a bank of synchronous DRAM (SDRAM) as well as up to four banks of asynchronous memory devices including flash, EPROM, ROM, SRAM, and memory mapped I/O devices.

The PC133-compliant SDRAM controller can be programmed to interface to up to 128M bytes of SDRAM. The SDRAM controller allows one row to be open for each internal SDRAM bank, for up to four internal SDRAM banks, improving overall system performance.

The asynchronous memory controller can be programmed to control up to four banks of devices with very flexible timing parameters for a wide variety of devices. Each bank occupies a 1M byte segment regardless of the size of the devices used, so that these banks will only be contiguous if each is fully populated with 1M byte of memory.

Flash Memory (ADSP-BF538F8 Only)

The ADSP-BF538F8 processor contains a separate flash die, connected to the EBIU bus, within the package of the processor. Figure 4 shows how the flash memory die and Blackfin processor die are connected.

The ADSP-BF538F8 contains an 8M bit (512K × 16-bit) bottom boot sector Spansion S29AL008J known good die flash memory. For additional information, visit www.spansion.com. Features include the following:

- Access times as fast as 70 ns (EBIU registers must be set appropriately)
- Sector protection
- One million write cycles per sector
- 20 year data retention

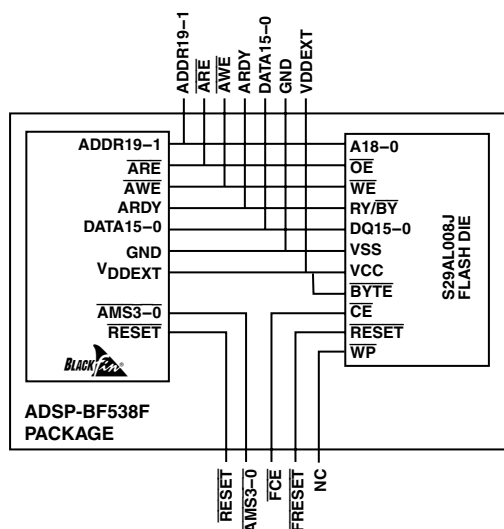

Figure 4. Internal Connection of Flash Memory (ADSP-BF538F8)

The Blackfin processor connects to the flash memory die with address, data, chip enable, write enable, and output enable controls as if it were an external memory device. Note that the write-protect input pin to the flash is not connected and inaccessible, disabling this feature.

The flash chip enable pin \overline{FCE} must be connected to $\overline{AMS0}$ or $\overline{AMS3-1}$ through a printed circuit board trace. When connected to $\overline{AMS0}$, the Blackfin processor can boot from the flash die. When connected to $\overline{AMS3-1}$, the flash memory appears as non-volatile memory in the processor memory map, shown in Figure 3.

Flash Memory Programming

The ADSP-BF538F8 flash memory can be programmed before or after mounting on the printed circuit board.

To program the flash prior to mounting on the printed circuit board, use a hardware programming tool that can provide the data, address, and control stimuli to the flash die through the external pins on the package. During this programming, V_{DDEXT} and GND must be provided to the package and the Blackfin must be held in reset with bus request (\overline{BR}) asserted and a CLKIN provided.

The VisualDSP++ tools can be used to program the flash memory after the device is mounted on a printed circuit board.

Flash Memory Sector Protection

To use the sector protection feature, a high voltage (+12 V nominal) must be applied to the flash \overline{FRESET} pin. Refer to the flash data sheet for details.

I/O Memory Space

Blackfin processors do not define a separate I/O space. All resources are mapped through the flat 32-bit address space. On-chip I/O devices have their control registers mapped into memory mapped registers (MMRs) at addresses near the top of the 4G byte address space. These are separated into two smaller blocks, one which contains the control MMRs for all core functions, and the other which contains the registers needed for setup and control of the on-chip peripherals outside of the core. The MMRs are accessible only in supervisor mode and appear as reserved space to on-chip peripherals.

Booting

The ADSP-BF538/ADSP-BF538F processors contain a small boot kernel, which configures the appropriate peripheral for booting. If the processor is configured to boot from boot ROM memory space, the processor starts executing from the on-chip boot ROM. For more information, see [Booting Modes on Page 16](#).

Event Handling

The event controller on the ADSP-BF538/ADSP-BF538F processors handle all asynchronous and synchronous events to the processors. The processor provides event handling that supports both nesting and prioritization. Nesting allows multiple event service routines to be active simultaneously. Prioritization

ensures that servicing of a higher priority event takes precedence over servicing of a lower priority event. The controller provides support for five different types of events:

- Emulation – An emulation event causes the processor to enter emulation mode, allowing command and control of the processor via the JTAG interface.
- Reset – This event resets the processor.
- Nonmaskable interrupt (NMI) – The NMI event can be generated by the software watchdog timer or by the NMI input signal to the processor. The NMI event is frequently used as a power-down indicator to initiate an orderly shut-down of the system.
- Exceptions – Events that occur synchronously to program flow (the exception is taken before the instruction is allowed to complete). Conditions such as data alignment violations and undefined instructions cause exceptions.
- Interrupts – Events that occur asynchronously to program flow. They are caused by input pins, timers, and other peripherals, as well as by an explicit software instruction.

Each event type has an associated register to hold the return address and an associated return-from-event instruction. When an event is triggered, the state of the processors is saved on the supervisor stack.

The ADSP-BF538/ADSP-BF538F processors' event controllers consist of two stages, the core event controller (CEC) and the system interrupt controller (SIC). The core event controller works with the system interrupt controller to prioritize and control all system events. Conceptually, interrupts from the peripherals enter into the SIC and are then routed directly into the general-purpose interrupts of the CEC.

Core Event Controller (CEC)

The CEC supports nine general-purpose interrupts (IVG15–7), in addition to the dedicated interrupt and exception events. Of these general-purpose interrupts, the two lowest priority interrupts (IVG15–14) are recommended to be reserved for software interrupt handlers, leaving seven prioritized interrupt inputs to support the peripherals of the processor.

Table 2 describes the inputs to the CEC, identifies their names in the event vector table (EVT), and lists their priorities.

System Interrupt Controller (SIC)

The system interrupt controllers (SIC) provides the mapping and routing of events from the many peripheral interrupt sources to the prioritized general-purpose interrupt inputs of the CEC. Although the ADSP-BF538/ADSP-BF538F processors provide a default mapping, programs can alter the mappings and priorities of interrupt events by writing the appropriate values into the interrupt assignment registers (SIC_IARx).

Table 3 describes the inputs into the SIC and the default mappings into the CEC.

Table 2. Core Event Controller (CEC)

Priority (0 is Highest)	Event Class	EVT Entry
0	Emulation/Test Control	EMU
1	Reset	RST

Event Control

The ADSP-BF538/ADSP-BF538F processors provide the user with a very flexible mechanism to control the processing of events. In the CEC, three registers are used to coordinate and control events. Each register is 32 bits wide:

- CEC interrupt latch register (ILAT) – The ILAT register indicates when events have been latched. The appropriate bit is set when the processor has latched the event and cleared when the event has been accepted into the system. This register is updated automatically by the controller, but it may also be written to clear (cancel) latched events. This register may be read while in supervisor mode and may only be written while in supervisor mode when the corresponding IMASK bit is cleared.
- CEC interrupt mask register (IMASK) – The IMASK register controls the masking and unmasking of individual events. When a bit is set in the IMASK register, that event is unmasked and will be processed by the CEC when asserted. A cleared bit in the IMASK register masks the event, preventing the processor from servicing the event even though the event may be latched in the ILAT register. This register

may be read or written while in supervisor mode. General-purpose interrupts can be globally enabled and disabled with the STI and CLI instructions, respectively.

- CEC interrupt pending register (IPEND) – The IPEND register keeps track of all nested events. A set bit in the IPEND register indicates the event is currently active or nested at some level. This register is updated automatically by the controller but may be read while in supervisor mode.

The SIC allows further control of event processing by providing three 32-bit interrupt control and status registers. Each register contains a bit corresponding to each of the peripheral interrupt events shown in [Table 3 on Page 7](#).

- SIC interrupt mask registers (SIC_IMASKx) – These registers control the masking and unmasking of each peripheral interrupt event. When a bit is set in these registers, that peripheral event is unmasked and will be processed by the system when asserted. A cleared bit in these registers masks the peripheral event, preventing the processor from servicing the event.
- SIC interrupt status registers (SIC_ISRx) – As multiple peripherals can be mapped to a single event, these registers allow the software to determine which peripheral event source triggered the interrupt. A set bit indicates the peripheral is asserting the interrupt, and a cleared bit indicates the peripheral is not asserting the event.
- SIC interrupt wake-up enable registers (SIC_IWRx) – By enabling the corresponding bit in these registers, a peripheral can be configured to wake up the processor, should the core be idled or in sleep mode when the event is generated. (For more information, see [Dynamic Power Management on Page 13](#).)

Because multiple interrupt sources can map to a single general-purpose interrupt, multiple pulse assertions can occur simultaneously, before or during interrupt processing for an interrupt event already detected on this interrupt input. The IPEND register contents are monitored by the SICs as the interrupt acknowledgement.

The appropriate ILAT register bit is set when an interrupt rising edge is detected (detection requires two core clock cycles). The bit is cleared when the respective IPEND register bit is set. The IPEND bit indicates that the event has entered into the processor pipeline. At this point the CEC will recognize and queue the next rising edge event on the corresponding event input. The minimum latency from the rising edge transition of the general-purpose interrupt to the IPEND output asserted is three core clock cycles; however, the latency can be much higher, depending on the activity within and the state of the processor.

DMA CONTROLLERS

The ADSP-BF538/ADSP-BF538F processors have two, independent DMA controllers that support automated data transfers with minimal overhead for the processor core. DMA transfers can occur between the processor internal memories and any of its DMA capable peripherals. Additionally, DMA transfers can be accomplished between any of the DMA capable peripherals and external devices connected to the external memory inter-

faces, including the SDRAM controller and the asynchronous memory controller. DMA capable peripherals include the SPORTs, SPI ports, UARTs, and PPI. Each individual DMA capable peripheral has at least one dedicated DMA channel.

The DMA controllers support both 1-dimensional (1-D) and 2-dimensional (2-D) DMA transfers. DMA transfer initialization can be implemented from registers or from sets of parameters called descriptor blocks.

The 2-D DMA capability supports arbitrary row and column sizes up to 64K elements by 64K elements, and arbitrary row and column step sizes up to $\pm 32K$ elements. Furthermore, the column step size can be less than the row step size, allowing implementation of interleaved data streams. This feature is especially useful in video applications where data can be deinterleaved on the fly.

Examples of DMA types supported by the processor DMA controller include:

- A single, linear buffer that stops upon completion
- A circular, auto-refreshing buffer that interrupts on each full or fractionally full buffer
- 1-D or 2-D DMA using a linked list of descriptors
- 2-D DMA using an array of descriptors, specifying only the base DMA address within a common page

In addition to the dedicated peripheral DMA channels, there are four memory DMA channels provided for transfers between the various memories of the ADSP-BF538/ADSP-BF538F processor's systems. This enables transfers of blocks of data between any of the memories—including external SDRAM, ROM, SRAM, and flash memory—with minimal processor intervention. Memory DMA transfers can be controlled by a very flexible descriptor based methodology or by a standard register based autobuffer mechanism.

REAL-TIME CLOCK

The ADSP-BF538/ADSP-BF538F processors' real-time clock (RTC) provides a robust set of digital watch features, including current time, stopwatch, and alarm. The RTC is clocked by a 32.768 kHz crystal external to the processor. The RTC peripheral has dedicated power supply pins so that it can remain powered up and clocked even when the rest of the processors are in a low power state. The RTC provides several programmable interrupt options, including interrupt per second, minute, hour, or day clock ticks, interrupt on programmable stopwatch countdown, or interrupt at a programmed alarm time.

The 32.768 kHz input clock frequency is divided down to a 1 Hz signal by a prescaler. The counter function of the timer consists of four counters: a 60 second counter, a 60 minute counter, a 24 hour counter, and a 32,768 day counter.

When enabled, the alarm function generates an interrupt when the output of the timer matches the programmed value in the alarm control register. There are two alarms: The first alarm is for a time of day. The second alarm is for a day and time of that day.

The stopwatch function counts down from a programmed value, with one second resolution. When the stopwatch is enabled and the counter underflows, an interrupt is generated.

Like the other peripherals, the RTC can wake up the processors from sleep mode upon generation of any RTC wake-up event. Additionally, an RTC wake-up event can wake up the processor from deep sleep mode and wake up the on-chip internal voltage regulator from the powered down hibernate state.

Connect RTC pins RTXI and RTXO with external components as shown in Figure 5.

SUGGESTED COMPONENTS:
 ECLIPTEK EC38J (THROUGH-HOLE PACKAGE)
 EPSON MC405 12 pF LOAD (SURFACE-MOUNT PACKAGE)
 C1 = 22pF
 C2 = 22pF
 R1 = 10M Ω

NOTE: C1 AND C2 ARE SPECIFIC TO CRYSTAL SPECIFIED FOR X1. CONTACT CRYSTAL MANUFACTURER FOR DETAILS. C1 AND C2 SPECIFICATIONS ASSUME BOARD TRACE CAPACITANCE OF 3pF.

Figure 5. External Components for RTC

WATCHDOG TIMER

The ADSP-BF538/ADSP-BF538F processors include a 32-bit timer that can be used to implement a software watchdog function. A software watchdog can improve system availability by forcing the processor to a known state through generation of a hardware reset, nonmaskable interrupt (NMI), or general-purpose interrupt, if the timer expires before being reset by software. The programmer initializes the count value of the timer, enables the appropriate interrupt, then enables the timer. Thereafter, the software must reload the counter before it counts to zero from the programmed value. This protects the system from remaining in an unknown state where software, which would normally reset the timer, has stopped running due to an external noise condition or software error.

If configured to generate a hardware reset, the watchdog timer resets both the core and the processor peripherals. After a reset, software can determine if the watchdog was the source of the hardware reset by interrogating a status bit in the watchdog timer control register.

The timer is clocked by the system clock (SCLK) at a maximum frequency of f_{SCLK} .

TIMERS

There are four general-purpose programmable timer units in the ADSP-BF538/ADSP-BF538F processors. Three timers have an external pin that can be configured either as a pulse-width modulator (PWM) or timer output, as an input to clock the

ADSP-BF538/ADSP-BF538F

timer, or as a mechanism for measuring pulse widths and periods of external events. These timers can be synchronized to an external clock input to the PF1 pin (TACLK), an external clock input to the PPI_CLK pin (TMRCLK), or to the internal SCLK.

The timer units can be used in conjunction with UART0 to measure the width of the pulses in the data stream to provide an auto-baud detect function for a serial channel.

The timers can generate interrupts to the processor core providing periodic events for synchronization, either to the system clock or to a count of external signals.

In addition to the three general-purpose programmable timers, a fourth timer is also provided. This extra timer is clocked by the internal processor clock and is typically used as a system tick clock for generation of operating system periodic interrupts.

SERIAL PORTS (SPORTs)

The ADSP-BF538/ADSP-BF538F processors incorporate four dual-channel synchronous serial ports for serial and multiprocessor communications. The SPORTs support the following features:

- I²S capable operation.
- Bidirectional operation – Each SPORT has two sets of independent transmit and receive pins, enabling 16 channels of I²S stereo audio.
- Buffered (8-deep) transmit and receive ports – Each port has a data register for transferring data words to and from other processor components and shift registers for shifting data in and out of the data registers.
- Clocking – Each transmit and receive port can either use an external serial clock or generate its own, in frequencies ranging from ($f_{SCLK}/131,070$) Hz to ($f_{SCLK}/2$) Hz.
- Word length – Each SPORT supports serial data words from 3 bits to 32 bits in length, transferred most significant bit first or least significant bit first.
- Framing – Each transmit and receive port can run with or without frame sync signals for each data word. Frame sync signals can be generated internally or externally, active high or low, and with either of two pulse widths and early or late frame sync.
- Companding in hardware – Each SPORT can perform A-law or μ -law companding according to ITU recommendation G.711. Companding can be selected on the transmit and/or receive channel of the SPORT without additional latencies.
- DMA operations with single-cycle overhead – Each SPORT can automatically receive and transmit multiple buffers of memory data. The processor can link or chain sequences of DMA transfers between a SPORT and memory.

- Interrupts – Each transmit and receive port generates an interrupt upon completing the transfer of a data word or after transferring an entire data buffer or buffers through DMA.
- Multichannel capability – Each SPORT supports 128 channels out of a 1024 channel window and is compatible with the H.100, H.110, MVIP-90, and HMVIP standards.

SERIAL PERIPHERAL INTERFACE (SPI) PORTS

The ADSP-BF538/ADSP-BF538F processors incorporate three SPI-compatible ports that enable the processor to communicate with multiple SPI compatible devices.

The SPI interface uses three pins for transferring data: two data pins (master output-slave input, MOSI_x, and master input-slave output, MISO_x) and a clock pin (serial clock, SCK_x). An SPI chip select input pin (\overline{SPIxSS}) lets other SPI devices select the processor. For SPI0, seven SPI chip select output pins ($\overline{SPI0SEL7-I}$) let the processor select other SPI devices. SPI1 and SPI2 each have a single SPI chip select output pin ($\overline{SPI1SEL1}$ and $\overline{SPI2SEL1}$) for SPI point-to-point communication. Each of the SPI select pins are reconfigured GPIO pins. Using these pins, the SPI ports provide a full-duplex, synchronous serial interface, which supports both master/slave modes and multi-master environments.

The SPI ports' baud rate and clock phase/polarities are programmable, and they each have an integrated DMA controller, configurable to support transmit or receive data streams. Each SPI's DMA controller can only service unidirectional accesses at any given time.

The SPI port's clock rate is calculated as:

$$SPI \text{ Clock Rate} = \frac{f_{SCLK}}{2 \times SPIx_BAUD}$$

where the 16-bit $SPIx_BAUD$ register contains a value of 2 to 65,535.

During transfers, the SPI port simultaneously transmits and receives by serially shifting data in and out on its two serial data lines. The serial clock line synchronizes the shifting and sampling of data on the two serial data lines.

2-WIRE INTERFACE

The ADSP-BF538/ADSP-BF538F processors have two 2-wire interface (TWI) modules that are compatible with the Philips Inter-IC bus standard. The TWI modules offer the capabilities of simultaneous master and slave operation, support for 7-bit addressing and multimedia data arbitration. The TWI also includes master clock synchronization and support for clock low extension.

The TWI interface uses two pins for transferring clock (SCL_x) and data (SDA_x) and supports the protocol at speeds up to 400 kbps.

The TWI interface pins are compatible with 5 V logic levels.

UART PORTS

The ADSP-BF538/ADSP-BF538F processors incorporate three full-duplex universal asynchronous receiver/transmitter (UART) ports, which are fully compatible with PC standard UARTs. The UART ports provide a simplified UART interface to other peripherals or hosts, supporting full-duplex, DMA supported, asynchronous transfers of serial data. The UART ports include support for 5 data bits to 8 data bits, 1 stop bit or 2 stop bits, and none, even, or odd parity. The UART ports support two modes of operation:

- PIO (programmed I/O) – The processor sends or receives data by writing or reading I/O mapped UART registers. The data is double buffered on both transmit and receive.
- DMA (direct memory access) – The DMA controller transfers both transmit and receive data. This reduces the number and frequency of interrupts required to transfer data to and from memory. Each UART has two dedicated DMA channels, one for transmit and one for receive. These DMA channels have lower default priority than most DMA channels because of their relatively low service rates.

Each UART port's baud rate, serial data format, error code generation and status, and interrupts are programmable:

- Supporting bit rates ranging from ($f_{SCLK}/1,048,576$) to ($f_{SCLK}/16$) bits per second.
- Supporting data formats from 7 to 12 bits per frame.
- Both transmit and receive operations can be configured to generate maskable interrupts to the processor.

Each UART port's clock rate is calculated as:

$$UART\ Clock\ Rate = \frac{f_{SCLK}}{16 \times UART_Divisor}$$

where the 16-bit *UART_Divisor* comes from the UARTx_DLH register (most significant 8 bits) and UARTx_DLL register (least significant 8 bits).

In conjunction with the general-purpose timer functions, auto-baud detection is supported on UART0.

The capabilities of the UARTs are further extended with support for the Infrared Data Association (IrDA[®]) Serial Infrared Physical Layer Link Specification (SIR) protocol.

GENERAL-PURPOSE PORTS

The ADSP-BF538/ADSP-BF538F processors have up to 54 general-purpose I/O pins that are multiplexed with other peripherals. They are arranged into Ports C, D, E, and F as shown in [Table 4](#).

The general-purpose I/O pins may be individually controlled by manipulation of the control and status registers. These pins may be polled to determine their status.

- GPIO direction control register – Specifies the direction of each individual GPIO pin as input or output.
- GPIO control and status registers – The processor employs a “write one to modify” mechanism that allows any combination of individual GPIO to be modified in a single

instruction, without affecting the level of any other GPIO. Four control registers and a data register are provided for each GPIO port. One register is written in order to set GPIO values, one register is written in order to clear GPIO values, one register is written in order to toggle GPIO values, and one register is written in order to specify a GPIO input or output. Reading the GPIO data allows software to determine the state of the input GPIO pins.

In addition to the GPIO function described above, the 16 Port F pins can be individually configured to generate interrupts.

- GPIO pin interrupt mask registers – The two GPIO pin interrupt mask registers allow each individual PFX pin to function as an interrupt to the processor. Similar to the two GPIO control registers that are used to set and clear individual GPIO pin values, one GPIO pin interrupt mask register sets bits to enable interrupt function, and the other GPIO pin interrupt mask register clears bits to disable interrupt function. PFX pins defined as inputs can be configured to generate hardware interrupts, while output PFX pins can be triggered by software interrupts.
- GPIO pin interrupt sensitivity registers – The two GPIO pin interrupt sensitivity registers specify whether individual PFX pins are level- or edge-sensitive and specify—if edge-sensitive—whether just the rising edge or both the rising and falling edges of the signal are significant. One register selects the type of sensitivity, and one register selects which edges are significant for edge-sensitivity.

Table 4. GPIO Ports

Peripheral	Alternate GPIO Port Function
PPI	GPIO Port F15–3
SPORT2	GPIO Port E7–0
SPORT3	GPIO Port E15–8
SPI0	GPIO Port F7–0
SPI1	GPIO Port D4–0
SPI2	GPIO Port D9–5
UART1	GPIO Port D11–10
UART2	GPIO Port D13–12
CAN	GPIO Port C1–0
GPIO	GPIO Port C9–4 ¹

¹ These pins are GPIO only and cannot be reconfigured through software. PC1 and PC4 are open-drain when configured as GPIO outputs.

PARALLEL PERIPHERAL INTERFACE

The ADSP-BF538/ADSP-BF538F processors provide a parallel peripheral interface (PPI) that can connect directly to parallel ADC and DAC converters, video encoders and decoders, and other general-purpose peripherals. The PPI consists of a dedicated input clock pin, up to 3 frame synchronization pins, and up to 16 data pins. The input clock supports parallel data rates at up to $f_{SCLK}/2$ MHz, and the synchronization signals can be configured as either inputs or outputs.

ADSP-BF538/ADSP-BF538F

The PPI supports a variety of general-purpose and ITU-R 656 modes of operation. In general-purpose mode, the PPI provides half-duplex, bidirectional data transfer with up to 16 bits of data. Up to 3 frame synchronization signals are also provided. In ITU-R 656 mode, the PPI provides half-duplex, bi-directional transfer of 8- or 10-bit video data. Additionally, on-chip decode of embedded start-of-line (SOL) and start-of-field (SOF) preamble packets is supported.

General-Purpose Mode Descriptions

The general-purpose modes of the PPI are intended to suit a wide variety of data capture and transmission applications. Three distinct submodes are supported:

- Input mode – frame syncs and data are inputs into the PPI.
- Frame capture mode – frame syncs are outputs from the PPI, but data are inputs.
- Output mode – frame syncs and data are outputs from the PPI.

Input Mode

Input mode is intended for ADC applications, as well as video communication with hardware signaling. In its simplest form, PPI_FS1 is an external frame sync input that controls when to read data. The PPI_DELAY MMR allows for a delay (in PPI_CLK cycles) between reception of this frame sync and the initiation of data reads. The number of input data samples is user programmable and defined by the contents of the PPI_COUNT register. The PPI supports 8-bit, and 10-bit through 16-bit data, and is programmable in the PPI_CONTROL register.

Frame Capture Mode

Frame capture mode allows the video source(s) to act as a slave (e.g., for frame capture). The ADSP-BF538/ADSP-BF538F processors control when to read from the video source(s). PPI_FS1 is an HSYNC output and PPI_FS2 is a VSYNC output.

Output Mode

Output mode is used for transmitting video or other data with up to three output frame syncs. Typically, a single frame sync is appropriate for data converter applications, whereas two or three frame syncs could be used for sending video with hardware signaling.

ITU-R 656 Mode Descriptions

The ITU-R 656 modes of the PPI are intended to suit a wide variety of video capture, processing, and transmission applications. Three distinct submodes are supported:

- Active video only mode
- Vertical blanking only mode
- Entire field mode

Active Video Only Mode

Active video only mode is used when only the active video portion of a field is of interest and not any of the blanking intervals. The PPI does not read in any data between the end of active

video (EAV) and start of active video (SAV) preamble symbols, or any data present during the vertical blanking intervals. In this mode, the control byte sequences are not stored to memory; they are filtered by the PPI. After synchronizing to the start of Field 1, the PPI ignores incoming samples until it sees an SAV code. The user specifies the number of active video lines per frame (in PPI_COUNT register).

Vertical Blanking Interval Mode

In this mode, the PPI only transfers vertical blanking interval (VBI) data.

Entire Field Mode

In this mode, the entire incoming bit stream is read in through the PPI. This includes active video, control preamble sequences, and ancillary data that may be embedded in horizontal and vertical blanking intervals. Data transfer starts immediately after synchronization to Field 1.

CONTROLLER AREA NETWORK (CAN) INTERFACE

The ADSP-BF538/ADSP-BF538F processors provide a CAN controller that is a communication controller implementing the Controller Area Network (CAN) V2.0B protocol. This protocol is an asynchronous communications protocol used in both industrial and automotive control systems. CAN is well suited for control applications due to its capability to communicate reliably over a network since the protocol incorporates CRC checking, message error tracking, and fault node confinement.

The CAN controller is based on a 32-entry mailbox RAM and supports both the standard and extended identifier (ID) message formats specified in the CAN protocol specification, revision 2.0, part B.

Each mailbox consists of eight 16-bit data words. The data is divided into fields, which includes a message identifier, a time stamp, a byte count, up to 8 bytes of data, and several control bits. Each node monitors the messages being passed on the network. If the identifier in the transmitted message matches an identifier in one of its mailboxes, then the module knows that the message was meant for it, passes the data into its appropriate mailbox, and signals the processor of message arrival with an interrupt.

The CAN controller can wake up the processor from sleep mode upon generation of a wake-up event, such that the processor can be maintained in a low power mode during idle conditions. Additionally, a CAN wake-up event can wake up the on-chip internal voltage regulator from the powered-down hibernate state.

The electrical characteristics of each network connection are very stringent, therefore the CAN interface is typically divided into 2 parts: a controller and a transceiver. This allows a single controller to support different drivers and CAN networks. The ADSP-BF538/ADSP-BF538F CAN module represents the controller part of the interface. This module's network I/O is a single transmit output and a single receive input, which connect to a line transceiver.

The CAN clock is derived from the processor system clock (SCLK) through a programmable divider and therefore does not require an additional crystal.

DYNAMIC POWER MANAGEMENT

The ADSP-BF538/ADSP-BF538F processors provide four operating modes, each with a different performance/power profile. In addition, dynamic power management provides the control functions to dynamically alter the processor core supply voltage, further reducing power dissipation. Control of clocking to each of the processor peripherals also reduces power consumption. See [Table 5](#) for a summary of the power settings for each mode.

Full-On Operating Mode—Maximum Performance

In the full-on mode, the PLL is enabled and is not bypassed, providing capability for maximum operational frequency. This is the power-up default execution state in which maximum performance can be achieved. The processor core and all enabled peripherals run at full speed.

Active Operating Mode—Moderate Dynamic Power Savings

In the active mode, the PLL is enabled but bypassed. Because the PLL is bypassed, the processor's core clock (CCLK) and system clock (SCLK) run at the input clock (CLKIN) frequency. DMA access is available to appropriately configured L1 memories.

In the active mode, it is possible to disable the PLL through the PLL Control register (PLL_CTL). If disabled, the PLL must be re-enabled before transitioning to the full-on or sleep modes.

Table 5. Power Settings

Mode	PLL	PLL Bypassed	Core Clock (CCLK)	System Clock (SCLK)	Internal Power (V _{DDINT})
Full On	Enabled	No	Enabled	Enabled	On
Active	Enabled/Disabled	Yes	Enabled	Enabled	On
Sleep	Enabled	—	Disabled	Enabled	On
Deep Sleep	Disabled	—	Disabled	Disabled	On
Hibernate	Disabled	—	Disabled	Disabled	Off

Sleep Operating Mode—High Dynamic Power Savings

The sleep mode reduces dynamic power dissipation by disabling the clock to the processor core (CCLK). The PLL and system clock (SCLK), however, continue to operate in this mode. Typically, an external event or RTC activity will wake up the processor. When in the sleep mode, assertion of a wake-up event enabled in the SIC_IWRx register causes the processor to sense the value of the BYPASS bit in the PLL control register (PLL_CTL). If BYPASS is disabled, the processor transitions to the full on mode. If BYPASS is enabled, the processor will transition to the active mode. When in the sleep mode, system DMA access to L1 memory is not supported.

Deep Sleep Operating Mode—Maximum Dynamic Power Savings

The deep sleep mode maximizes dynamic power savings by disabling the clocks to the processor core (CCLK) and to all synchronous peripherals (SCLK). Asynchronous peripherals such as the RTC may still be running, but will not be able to access internal resources or external memory. This powered down mode can only be exited by assertion of the reset interrupt (RESET) or by an asynchronous interrupt generated by the RTC. When in deep sleep mode, an RTC asynchronous interrupt causes the processor to transition to the active mode. Assertion of RESET while in deep sleep mode causes the processor to transition to the full-on mode after processor reset.

Hibernate State—Maximum Static Power Savings

The hibernate state maximizes static power savings by disabling the voltage and clocks to the processor core (CCLK) and to all of the synchronous peripherals (SCLK). The internal voltage regulator for the processor can be shut off by writing b#00 to the `FREQ` bits of the `VR_CTL` register. This disables both CCLK and SCLK. Also, disabling these clocks, sets the internal power supply voltage (V_{DDINT}) to 0 V to provide the greatest power savings. To preserve the processor state, prior to removing power, any critical information stored internally (memory contents, register contents, and others) must be written to a nonvolatile storage device.

Because V_{DDEXT} is still supplied in clocks-disabled state, all of the external pins three-state, unless otherwise specified. This state allows other devices that are connected to the processor to still have power applied without drawing unwanted current.

There are a number of methods for wake up. The CAN module can wake up the internal supply regulator. Additionally, the `GPW` pin can be pulled low by any other device to wake up the processor. Finally, the regulator can also be woken up by a real-time clock wake-up event or by asserting the `RESET` pin. All hibernate wake-up events initiate the hardware reset sequence. Individual sources are enabled by the `VR_CTL` register.

With the exception of the `VR_CTL` and the RTC registers, all internal registers and memories lose their content in the hibernate state. State variables can be held in external SRAM or SDRAM. The `SCKELOW` bit in the `VR_CTL` register provides a means of waking from hibernate state without disrupting a self-refreshing SDRAM, provided there is also an external pull-down on the `SCKE` pin.

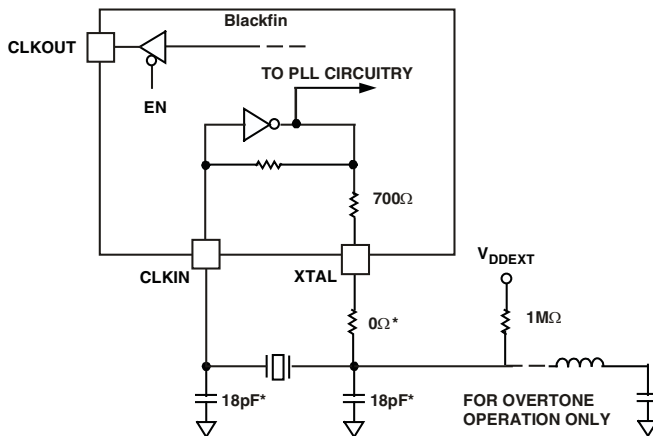

Power Savings

As shown in [Table 6](#), the ADSP-BF538/ADSP-BF538F processors support three different power domains. The use of multiple power domains maximizes flexibility, while maintaining compliance with industry standards and conventions. The 3.3 V V_{DDRTC} power domain supplies the RTC I/O and logic so that the RTC can remain functional when the rest of the chip is powered off. The 1.25 V V_{DDINT} power domain supplies all the

If an external clock is used, it should be a TTL-compatible signal and must not be halted, changed, or operated below the specified frequency during normal operation. This signal is connected to the processor's CLKIN pin. When an external clock is used, the XTAL pin must be left unconnected.

Alternatively, because the ADSP-BF538/ADSP-BF538F processors include an on-chip oscillator circuit, an external crystal may be used. For fundamental frequency operation, use the circuit shown in Figure 7. A parallel-resonant, fundamental frequency, microprocessor-grade crystal is connected across the CLKIN and XTAL pins. The on-chip resistance between CLKIN and the XTAL pin is in the 500 k Ω range. Further parallel resistors are typically not recommended. The two capacitors and the series resistor, shown in Figure 7, fine tune the phase and amplitude of the sine frequency. The capacitor and resistor values, shown in Figure 7, are typical values only. The capacitor values are dependent upon the crystal manufacturer's load capacitance recommendations and the physical PCB layout. The resistor value depends on the drive level specified by the crystal manufacturer. System designs should verify the customized values based on careful investigation on multiple devices over the allowed temperature range.

A third-overtone crystal can be used at frequencies above 25 MHz. The circuit is then modified to ensure crystal operation only at the third overtone, by adding a tuned inductor circuit as shown in Figure 7.

NOTE: VALUES MARKED WITH * MUST BE CUSTOMIZED DEPENDING ON THE CRYSTAL AND LAYOUT. PLEASE ANALYZE CAREFULLY.

Figure 7. External Crystal Connections

As shown in Figure 8, the core clock (CCLK) and system peripheral clock (SCLK) are derived from the input clock (CLKIN) signal. An on-chip PLL is capable of multiplying the CLKIN signal by a user programmable $0.5\times$ to $64\times$ multiplication factor (bounded by specified minimum and maximum VCO frequencies). The default multiplier is $10\times$, but it can be modified by a software instruction sequence. On-the-fly frequency changes can be effected by simply writing to the PLL_DIV register.

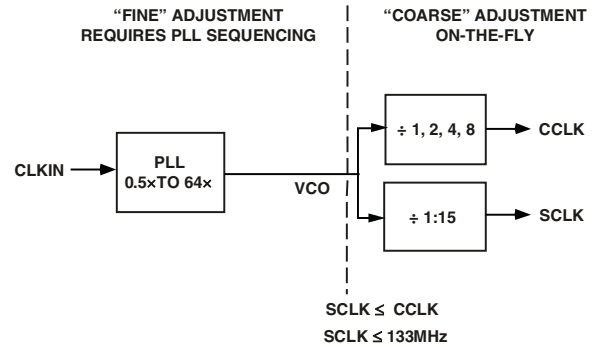

Figure 8. Frequency Modification Methods

All on-chip peripherals are clocked by the system clock (SCLK). The system clock frequency is programmable by means of the SSEL3–0 bits of the PLL_DIV register. The values programmed into the SSEL fields define a divide ratio between the PLL output (VCO) and the system clock. SCLK divider values are 1 through 15.

Table 7 illustrates typical system clock ratios:

Table 7. Example System Clock Ratios

Signal Name SSEL3–0	Divider Ratio VCO/SCLK	Example Frequency Ratios (MHz)	
		VCO	SCLK
0001	1:1	100	100
0110	6:1	300	50
1010	10:1	500	50

The maximum frequency of the system clock is f_{SCLK} . Note that the divisor ratio must be chosen to limit the system clock frequency to its maximum of f_{SCLK} . The SSEL value can be changed dynamically without any PLL lock latencies by writing the appropriate values to the PLL divisor register (PLL_DIV).

Note that when the SSEL value is changed, it will affect all the peripherals that derive their clock signals from the SCLK signal.

The core clock (CCLK) frequency can also be dynamically changed by means of the CSEL1–0 bits of the PLL_DIV register. Supported CCLK divider ratios are 1, 2, 4, and 8, as shown in Table 8. This programmable core clock capability is useful for fast core frequency modifications.

Table 8. Core Clock Ratios

Signal Name CSEL1–0	Divider Ratio VCO/CCLK	Example Frequency Ratios	
		VCO	CCLK
00	1:1	300	300
01	2:1	300	150
10	4:1	500	125
11	8:1	200	25

ADSP-BF538/ADSP-BF538F

BOOTING MODES

The ADSP-BF538/ADSP-BF538F processors have three mechanisms (listed in Table 9) for automatically loading internal L1 instruction memory after a reset. A fourth mode is provided to execute from external memory, bypassing the boot sequence.

Table 9. Booting Modes

BMODE1–0	Description
00	Execute from 16-Bit External Memory (Bypass Boot ROM)
01	Boot from 8-Bit or 16-Bit Flash, or Boot from On-Chip Flash (ADSP-BF538F Only)
10	Boot from SPI Serial Master Connected to SPI0
11	Boot from SPI Serial Slave EEPROM/Flash (8-, 16-, or 24-Bit Address Range, or Atmel AT45DB041, AT45DB081, or AT45DB161 Serial Flash) Connected to SPI0

The BMODE pins of the reset configuration register, sampled during power-on resets and software initiated resets, implement the following modes:

- Execute from 16-bit external memory – Execution starts from address 0x2000 0000 with 16-bit packing. The boot ROM is bypassed in this mode. All configuration settings are set for the slowest device possible (3-cycle hold time; 15-cycle R/W access times; 4-cycle setup).
- Boot from 8-bit or 16-bit external flash memory – The 8-bit flash boot routine located in boot ROM memory space is set up using asynchronous memory bank 0. For ADSP-BF538F processors, the on-chip flash is booted if FCE is connected to AMS0. All configuration settings are set for the slowest device possible (3-cycle hold time; 15-cycle R/W access times; 4-cycle setup).
- Boot from SPI serial EEPROM/flash (8-, 16-, or 24-bit addressable, or Atmel AT45DB041, AT45DB081, or AT45DB161) connected to SPI0– SPI0 uses the PF2 output pin to select a single SPI EEPROM/flash device, submits a read command and successive address bytes (0x00) until a valid 8-, 16-, or 24-bit, or Atmel addressable device is detected, and begins clocking data into the processor at the beginning of L1 instruction memory.
- Boot from SPI host device connected to SPI0 – The Blackfin processor operates in SPI slave mode and is configured to receive the bytes of the LDR file from an SPI host (master) agent. To hold off the host device from transmitting while the boot ROM is busy, the Blackfin processor asserts a GPIO pin, called host wait (HWAIT), to signal the host device not to send any more bytes until the flag is deasserted. The flag is chosen by the user and this information is transferred to the Blackfin processor via bits 10:5 of the FLAG header in the LDR image.

For each of the boot modes, a 10-byte header is first read from an external memory device. The header specifies the number of bytes to be transferred and the memory destination address.

Multiple memory blocks may be loaded by any boot sequence. Once all blocks are loaded, program execution commences from the start of L1 instruction SRAM.

In addition, Bit 4 of the reset configuration register can be set by application code to bypass the normal boot sequence during a software reset. For this case, the processor jumps directly to the beginning of L1 instruction memory.

To augment the boot modes, a secondary software loader is provided that adds additional booting mechanisms. This secondary loader provides the capability to boot from 16-bit flash memory, fast flash, variable baud rate, and other sources. In all boot modes except bypass, program execution starts from on-chip L1 memory address 0xFFA0 0000.

INSTRUCTION SET DESCRIPTION

The Blackfin processor family assembly language instruction set employs an algebraic syntax designed for ease of coding and readability. The instructions have been specifically tuned to provide a flexible, densely encoded instruction set that compiles to a very small final memory size. The instruction set also provides fully featured multifunction instructions that allow the programmer to use many of the processor core resources in a single instruction. Coupled with many features more often seen on microcontrollers, this instruction set is very efficient when compiling C and C++ source code. In addition, the architecture supports both user (algorithm/application code) and supervisor (O/S kernel, device drivers, debuggers, ISRs) modes of operation, allowing multiple levels of access to core processor resources.

The assembly language, which takes advantage of the processor's unique architecture, offers the following advantages:

- Seamlessly integrated DSP/CPU features are optimized for both 8-bit and 16-bit operations.
- A multi-issue load/store modified Harvard architecture, which supports two 16-bit MAC or four 8-bit ALU plus two load/store plus two pointer updates per cycle.
- All registers, I/O, and memory are mapped into a unified 4G byte memory space, providing a simplified programming model.
- Microcontroller features, such as arbitrary bit and bit-field manipulation, insertion, and extraction; integer operations on 8-, 16-, and 32-bit data types; and separate user and supervisor stack pointers.
- Code density enhancements, which include intermixing of 16- and 32-bit instructions (no mode switching, no code segregation). Frequently used instructions are encoded in 16 bits.

DEVELOPMENT TOOLS

Analog Devices supports its processors with a complete line of software and hardware development tools, including integrated development environments (which include CrossCore® Embedded Studio and/or VisualDSP++®), evaluation products, emulators, and a wide variety of software add-ins.

Integrated Development Environments (IDEs)

For C/C++ software writing and editing, code generation, and debug support, Analog Devices offers two IDEs.

The newest IDE, CrossCore Embedded Studio, is based on the Eclipse™ framework. Supporting most Analog Devices processor families, it is the IDE of choice for future processors, including multicore devices. CrossCore Embedded Studio seamlessly integrates available software add-ins to support real time operating systems, file systems, TCP/IP stacks, USB stacks, algorithmic software modules, and evaluation hardware board support packages. For more information visit www.analog.com/cces.

The other Analog Devices IDE, VisualDSP++, supports processor families introduced prior to the release of CrossCore Embedded Studio. This IDE includes the Analog Devices VDK real time operating system and an open source TCP/IP stack. For more information visit www.analog.com/visualdsp. Note that VisualDSP++ will not support future Analog Devices processors.

EZ-KIT Lite Evaluation Board

For processor evaluation, Analog Devices provides wide range of EZ-KIT Lite® evaluation boards. Including the processor and key peripherals, the evaluation board also supports on-chip emulation capabilities and other evaluation and development features. Also available are various EZ-Extenders®, which are daughter cards delivering additional specialized functionality, including audio and video processing. For more information visit www.analog.com and search on “ezkit” or “ezextender”.

EZ-KIT Lite Evaluation Kits

For a cost-effective way to learn more about developing with Analog Devices processors, Analog Devices offer a range of EZ-KIT Lite evaluation kits. Each evaluation kit includes an EZ-KIT Lite evaluation board, directions for downloading an evaluation version of the available IDE(s), a USB cable, and a power supply. The USB controller on the EZ-KIT Lite board connects to the USB port of the user's PC, enabling the chosen IDE evaluation suite to emulate the on-board processor in-circuit. This permits the customer to download, execute, and debug programs for the EZ-KIT Lite system. It also supports in-circuit programming of the on-board Flash device to store user-specific boot code, enabling standalone operation. With the full version of CrossCore Embedded Studio or VisualDSP++ installed (sold separately), engineers can develop software for supported EZ-KITs or any custom system utilizing supported Analog Devices processors.

Software Add-Ins for CrossCore Embedded Studio

Analog Devices offers software add-ins which seamlessly integrate with CrossCore Embedded Studio to extend its capabilities and reduce development time. Add-ins include board support packages for evaluation hardware, various middleware packages, and algorithmic modules. Documentation, help, configuration dialogs, and coding examples present in these add-ins are viewable through the CrossCore Embedded Studio IDE once the add-in is installed.

Board Support Packages for Evaluation Hardware

Software support for the EZ-KIT Lite evaluation boards and EZ-Extender daughter cards is provided by software add-ins called Board Support Packages (BSPs). The BSPs contain the required drivers, pertinent release notes, and select example code for the given evaluation hardware. A download link for a specific BSP is located on the web page for the associated EZ-KIT or EZ-Extender product. The link is found in the *Product Download* area of the product web page.

Middleware Packages

Analog Devices separately offers middleware add-ins such as real time operating systems, file systems, USB stacks, and TCP/IP stacks. For more information see the following web pages:

- www.analog.com/ucos3
- www.analog.com/ucfs
- www.analog.com/ucusbd
- www.analog.com/lwip

Algorithmic Modules

To speed development, Analog Devices offers add-ins that perform popular audio and video processing algorithms. These are available for use with both CrossCore Embedded Studio and VisualDSP++. For more information visit www.analog.com and search on “Blackfin software modules” or “SHARC software modules”.

Designing an Emulator-Compatible DSP Board (Target)

For embedded system test and debug, Analog Devices provides a family of emulators. On each JTAG DSP, Analog Devices supplies an IEEE 1149.1 JTAG Test Access Port (TAP). In-circuit emulation is facilitated by use of this JTAG interface. The emulator accesses the processor's internal features via the processor's TAP, allowing the developer to load code, set breakpoints, and view variables, memory, and registers. The processor must be halted to send data and commands, but once an operation is completed by the emulator, the DSP system is set to run at full speed with no impact on system timing. The emulators require the target board to include a header that supports connection of the DSP's JTAG port to the emulator.

For details on target board design issues including mechanical layout, single processor connections, signal buffering, signal termination, and emulator pod logic, see the Engineer-to-Engineer Note “Analog Devices JTAG Emulation Technical Reference” (EE-68) on the Analog Devices website (www.analog.com)—use site search on “EE-68.” This document is updated regularly to keep pace with improvements to emulator support.

ADDITIONAL INFORMATION

The following publications that describe the ADSP-BF538/ADSP-BF538F processors (and related processors) can be ordered from any Analog Devices sales office or accessed electronically on our website:

- *Getting Started with Blackfin Processors*
- *ADSP-BF538/ADSP-BF538F Blackfin Processor Hardware Reference*
- *ADSP-BF53x/ADSP-BF56x Blackfin Processor Programming Reference*
- *ADSP-BF538 Blackfin Processor Anomaly List*

RELATED SIGNAL CHAINS

A *signal chain* is a series of signal-conditioning electronic components that receive input (data acquired from sampling either real-time phenomena or from stored data) in tandem, with the output of one portion of the chain supplying input to the next. Signal chains are often used in signal processing applications to gather and process data or to apply system controls based on analysis of real-time phenomena. For more information about this term and related topics, see the "signal chain" entry in [Wikipedia](#) or the [Glossary of EE Terms](#) on the Analog Devices website.

Analog Devices eases signal processing system development by providing signal processing components that are designed to work together well. A tool for viewing relationships between specific applications and related components is available on the www.analog.com website.

The Application Signal Chains page in the Circuits from the Lab™ site (<http://www.analog.com/signalchains>) provides:

- Graphical circuit block diagram presentation of signal chains for a variety of circuit types and applications
- Drill down links for components in each chain to selection guides and application information
- Reference designs applying best practice design techniques

PIN DESCRIPTIONS

The ADSP-BF538/ADSP-BF538F processors pin definitions are listed in [Table 10](#).

All pins are three-stated during and immediately after reset, except the memory interface, asynchronous memory control, and synchronous memory control pins. These pins are all driven high, with the exception of CLKOUT, which toggles at the system clock rate. If $\overline{\text{BR}}$ is active (whether or not $\overline{\text{RESET}}$ is asserted), the memory pins are also three-stated. All unused I/O pins have their input buffers disabled with the exception of the

pins that need pull-ups or pull-downs, as noted in the table. During hibernate, all outputs are three-stated unless otherwise noted in [Table 10](#).

In order to maintain maximum functionality and reduce package size and pin count, some pins have dual, multiplexed functionality. In cases where pin functionality is reconfigurable, the default state is shown in plain text, while alternate functionality is shown in *italics*.

Table 10. Pin Descriptions

Pin Name	I/O	Function	Driver Type ¹
<i>Memory Interface</i>			
ADDR19–1	O	Address Bus for Async/Sync Access	A
DATA15–0	I/O	Data Bus for Async/Sync Access	A
$\overline{\text{ABE1}}\text{--}\overline{\text{0}}/\text{SDQM1--0}$	O	Byte Enables/Data Masks for Async/Sync Access	A
$\overline{\text{BR}}$	I	Bus Request (This pin should be pulled high when not used.)	
$\overline{\text{BG}}$	O	Bus Grant	A
$\overline{\text{BGH}}$	O	Bus Grant Hang	A
<i>Asynchronous Memory Control</i>			
$\overline{\text{AMS3}}\text{--}\overline{\text{0}}$	O	Bank Select (Require pull-ups if hibernate is used.)	A
ARDY	I	Hardware Ready Control	
$\overline{\text{AOE}}$	O	Output Enable	A
$\overline{\text{ARE}}$	O	Read Enable	A
$\overline{\text{AWE}}$	O	Write Enable	A
<i>Flash Control</i>			
$\overline{\text{FCE}}$	I	Flash Enable (This pin is internally connected to GND on the ADSP-BF538.)	
$\overline{\text{FRESET}}$	I	Flash Reset (This pin is internally connected to GND on the ADSP-BF538.)	
<i>Synchronous Memory Control</i>			
$\overline{\text{SRAS}}$	O	Row Address Strobe	A
$\overline{\text{SCAS}}$	O	Column Address Strobe	A
$\overline{\text{SWE}}$	O	Write Enable	A
SCKE	O	Clock Enable (This pin must be pulled low through a 10 k Ω resistor if hibernate state is used and SDRAM contents need to be preserved during hibernate.)	A
CLKOUT	O	Clock Output	B
SA10	O	A10 Pin	A
$\overline{\text{SMS}}$	O	Bank Select	A

$\overline{\text{NMI}}$	I	Nonmaskable Interrupt (This pin should be pulled high when not used.)	
BMODE1–0	I	Boot Mode Strap (These pins must be pulled to the state required for the desired boot mode.)	
<i>Voltage Regulator</i>			
VROUT1–0	O	External FET Drive 0 (These pins should be left unconnected when not used and are driven high during hibernate.)	
$\overline{\text{GPW}}$	I 5 V	General-Purpose Regulator Wake-Up (This pin should be pulled high when not used.)	
<i>Supplies</i>			
V _{DDEXT}	P	I/O Power Supply	
V _{DDINT}	P	Internal Power Supply	
V _{DDRTC}	P	Real-Time Clock Power Supply (This pin should be connected to V _{DDEXT} when not used and should remain powered at all times.)	
GND	G	Ground	

¹ Refer to [Figure 33 on Page 47](#) to [Figure 43 on Page 49](#).

² This pin is 5 V-tolerant when configured as an input and an open-drain when configured as an output; therefore, only the VOL curves in [Figure 37 on Page 48](#) and [Figure 38 on Page 48](#) and the Fall Time curves in [Figure 50 on Page 51](#) and [Figure 51 on Page 51](#) apply when configured as an output.

SPECIFICATIONS

Note that component specifications are subject to change without notice.

OPERATING CONDITIONS

Parameter		Conditions	Min	Nom	Max	Unit
V _{DDINT}	Internal Supply Voltage	533 MHz Speed Grade Models ^{1, 2}	0.8	1.25	1.375	V
V _{DDINT}	Internal Supply Voltage	400 MHz Speed Grade Models ^{1, 2}	0.8	1.2	1.32	V
V _{DDEXT}	External Supply Voltage	Models with on-chip flash ²	2.7	3.3	3.6	V
V _{DDEXT}	External Supply Voltage	Models without on-chip flash ^{2, 3}	2.25	3.0	3.6	V
V _{DDRTC}	Real-Time Clock Power Supply Voltage		2.25		3.6	V
V _{IH}	High Level Input Voltage ⁴	V _{DDEXT} = Maximum	2.0			V
V _{IHSV}	High Level Input Voltage ⁵	V _{DDEXT} = Maximum	2.0			V
V _{IHCLKIN}	High Level Input Voltage ⁶	V _{DDEXT} = Maximum	2.2			V
V _{IL}	Low Level Input Voltage ^{4, 7}	V _{DDEXT} = Minimum			+0.6	V
V _{ILSV}	Low Level Input Voltage ⁵	V _{DDEXT} = Minimum			+0.8	V
T _J	Junction Temperature	316-Ball Chip Scale Package Ball Grid Array (CSP_BGA) @ T _{AMBIENT} = −40°C to +85°C	−40		+110	°C

¹The regulator can generate V_{DDINT} at levels of 0.85 V to 1.2 V with -5% to +10% tolerance and 1.25 V with -4% to +10% tolerance

²See [Ordering Guide on Page 58](#).

³When V_{DDEXT} < 2.70 V, on-chip voltage regulation is not supported.

⁴The 3.3 V tolerant pins are capable of accepting up to 3.6 V maximum V_{IH}. The following bidirectional pins are 3.3 V tolerant: DATA15-0, SCK2-0, MISO2-0, MOSI2-0, PF15-0, PPI3-0, SPI1SS, SPI1SEL1, PC9-5, SPI2SS, SPI2SEL1, RX2-1, TX2-1, TSCLK3-0, RSCLK3-0, TFS3-0, RFS3-0, DT2PRI, DT2SEC, DR2PRI, DR2SEC, DT3PRI, DT3SEC, DR3PRI, DR3SEC, and TMR2-0. The following input-only pins are 3.3 V tolerant: RESET, RX0, TCK, TDI, TMS, TRST, ARDY, BMODE1-0, BR, DR0PRI, DR0SEC, DR1PRI, DR1SEC, NMI, PPI_CLK, and RTXI.

⁵The 5 V tolerant pins are capable of accepting up to 5.5 V maximum V_{IH}. The following bidirectional pins are 5 V tolerant: SCL0, SCL1, SDA0, SDA1, CANTX, CANRX, and PC4. The following input-only pin is 5 V tolerant: GPW.

⁶Parameter value applies to the CLKIN input pin.

⁷Parameter value applies to all input and bidirectional pins.

ADSP-BF538/ADSP-BF538F

The following tables describe the voltage/frequency requirements for the ADSP-BF538/ADSP-BF538F processor clocks. Take care in selecting MSEL, SSEL, and CSEL ratios so as not to exceed the maximum core clock (Table 11 and Table 12) and system clock (Table 14) specifications. Table 13 describes phase-locked loop operating conditions.

Table 11. Core Clock (CCLK) Requirements — 400 MHz Models

Parameter	Internal Regulator Setting	Max	Unit
f_{CCLK} CLK Frequency ($V_{\text{DDINT}} = 1.14 \text{ V}$ Minimum)	1.20 V	400	MHz
f_{CCLK} CLK Frequency ($V_{\text{DDINT}} = 1.045 \text{ V}$ Minimum)	1.10 V	364	MHz
f_{CCLK} CLK Frequency ($V_{\text{DDINT}} = 0.95 \text{ V}$ Minimum)	1.00 V	333	MHz
f_{CCLK} CLK Frequency ($V_{\text{DDINT}} = 0.85 \text{ V}$ Minimum)	0.90 V	280	MHz
f_{CCLK} CLK Frequency ($V_{\text{DDINT}} = 0.8 \text{ V}$ Minimum)	0.85 V	250	MHz

Table 12. Core Clock (CCLK) Requirements — 533 MHz Models

Parameter	Internal Regulator Setting	Max	Unit
f_{CCLK} Core Clock Frequency ($V_{\text{DDINT}} = 1.2 \text{ V}$ Minimum)	1.25 V	533	MHz
f_{CCLK} Core Clock Frequency ($V_{\text{DDINT}} = 1.14 \text{ V}$ Minimum)	1.20 V	500	MHz
f_{CCLK} Core Clock Frequency ($V_{\text{DDINT}} = 1.045 \text{ V}$ Minimum)	1.10 V	444	MHz
f_{CCLK} Core Clock Frequency ($V_{\text{DDINT}} = 0.95 \text{ V}$ Minimum)	1.00 V	400	MHz
f_{CCLK} Core Clock Frequency ($V_{\text{DDINT}} = 0.85 \text{ V}$ Minimum)	0.95 V	333	MHz
f_{CCLK} Core Clock Frequency ($V_{\text{DDINT}} = 0.8 \text{ V}$ Minimum)	0.85 V	250	MHz

Table 13. Phase-Locked Loop Operating Conditions

Parameter	Min	Max	Unit
f_{VCO} Voltage Controlled Oscillator (VCO) Frequency	50	$\text{Max } f_{\text{CCLK}}$	MHz

Table 14. System Clock (SCLK) Requirements

Parameter ¹	Max	Unit
f_{SCLK} CLKOUT/SCLK Frequency ($V_{\text{DDINT}} \geq 1.14 \text{ V}$)	133 ²	MHz
f_{SCLK} CLKOUT/SCLK Frequency ($V_{\text{DDINT}} < 1.14 \text{ V}$)	100	MHz

¹ $t_{\text{SCLK}} (= 1/f_{\text{SCLK}})$ must be greater than or equal to t_{CCLK} .

² Guaranteed to $t_{\text{SCLK}} = 7.5 \text{ ns}$. See Table 27 on page 33.

ELECTRICAL CHARACTERISTICS

Parameter ¹	Test Conditions	Min	Typ	Max	Unit
V _{OH}	High Level Output Voltage ²	V _{DDEXT} = +3.0 V, I _{OH} = -0.5 mA	2.4		V

I _{DDINT} ⁹	V _{DDINT} Current	f _{CCLK} > 0 MHz		I _{DDDEEPSLEEP} + (Table 17 × ASF)	mA

¹ Specifications subject to change without notice.

² Applies to output and bidirectional pins.

³ Applies to input pins except JTAG inputs.

⁴ Applies to JTAG input pins (TCK, TDI, TMS, TRST).

⁵ Applies to three-statable pins.

⁶ Applies to all signal pins.

⁷ Guaranteed, but not tested.

⁸ See the ADSP-BF538/538F Blackfin Processor Hardware Reference for definitions of sleep, deep sleep, and hibernate operating modes.

⁹ See Table 16 for the list of I_{DDINT} power vectors covered by various Activity Scaling Factors (ASF).

System designers should refer to *Estimating Power for the ADSP-BF538/BF539 Blackfin Processors (EE-298)*, which provides detailed information for optimizing designs for lowest power. All topics discussed in this section are described in detail in EE-298. Total power dissipation has two components:

1. Static, including leakage current
2. Dynamic, due to transistor switching characteristics

Many operating conditions can also affect power dissipation, including temperature, voltage, operating frequency, and processor activity. [Electrical Characteristics on Page 25](#) shows the current dissipation for internal circuitry (V_{DDINT}). I_{DDDEEPSLEEP} specifies static power dissipation as a function of voltage (V_{DDINT}) and temperature (see [Table 15](#)), and I_{DDINT} specifies the total power specification for the listed test conditions, including the dynamic component as a function of voltage (V_{DDINT}) and frequency ([Table 17](#)).

The dynamic component is also subject to an Activity Scaling Factor (ASF) which represents application code running on the processor ([Table 16](#)).

¹ The values are not guaranteed as standalone maximum specifications, they must be combined with static current per the equations of [Electrical Characteristics on Page 25](#).

ABSOLUTE MAXIMUM RATINGS

Stresses greater than those listed below may cause permanent damage to the device. These are stress ratings only. Functional operation of the device at these or any other conditions greater than those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Table 18. Absolute Maximum Ratings

Parameter	Rating
Internal (Core) Supply Voltage (V_{DDINT})	–0.3 V to +1.4 V
External (I/O) Supply Voltage (V_{DDEXT}) ¹	–0.3 V to +3.8 V
Input Voltage ^{2, 3}	–0.5 V to +3.6 V
Input Voltage ^{4, 4}	–0.5 V to +5.5 V
Output Voltage Swing	–0.5 V to $V_{DDEXT} + 0.5$ V
Junction Temperature While Biased	+125°C
Storage Temperature Range	–65°C to +150°C

¹ Parameter value applies also to V_{DDRTC} .

² Applies to 100% transient duty cycle. For other duty cycles, see Table 19.

³ Applies only when V_{DDEXT} is within specifications. When V_{DDEXT} is outside specifications, the range is $V_{DDEXT} \pm 0.2$ V.

⁴ Applies to pins designated as 5 V tolerant only.

Table 19. Maximum Duty Cycle for Input Transient Voltage¹

V_{IN} Min (V) ²	V_{IN} Max (V) ²	Maximum Duty Cycle ³
–0.50	+3.80	100%
–0.70	+4.00	40%
–0.80	+4.10	25%
–0.90	+4.20	15%
–1.00	+4.30	10%

¹ Applies to all signal pins with the exception of CLKIN, XTAL, and VROUT1–0.

² The individual values cannot be combined for analysis of a single instance of overshoot or undershoot. The worst case observed value must fall within one of the voltages specified and the total duration of the overshoot or undershoot (exceeding the 100% case) must be less than or equal to the corresponding duty cycle.

³ Duty cycle refers to the percentage of time the signal exceeds the value for the 100% case. This is equivalent to the measured duration of a single instance of overshoot or undershoot as a percentage of the period of occurrence.

ESD SENSITIVITY

	<p>ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.</p>

TIMING SPECIFICATIONS

Component specifications are subject to change with PCN notice.

Clock and Reset Timing

Table 21 and Figure 10 describe clock and reset operations. Per Absolute Maximum Ratings on Page 27, combinations of CLKIN and clock multipliers must not select core/peripheral clocks that exceed maximum operating conditions.

Table 21. Clock and Reset Timing

Parameter		Min	Max	Unit
<i>Timing Requirements</i>				
f_{CKIN}	CLKIN Frequency (Commercial/ Industrial Models) ^{1,2,3,4}	10	50	MHz
t_{CKINL}	CLKIN Low Pulse ¹	8		ns
t_{CKINH}	CLKIN High Pulse ¹	8		ns
t_{WRST}	\overline{RESET} Asserted Pulse Width Low ⁵	$11 \times t_{CKIN}$		ns
t_{NOBOOT}	\overline{RESET} Deassertion to First External Access Delay ⁶	$3 \times t_{CKIN}$	$5 \times t_{CKIN}$	ns

¹ Applies to PLL bypass mode and PLL nonbypass mode.

² Combinations of the CLKIN frequency and the PLL clock multiplier must not exceed the allowed f_{VCO} , f_{CLKK} , and f_{SCLK} settings discussed in Table 11 on Page 24 through Table 16 on Page 26.

³ The t_{CKIN} period (see Figure 10) equals $1/f_{CKIN}$.

⁴ If the DF bit in the PLL_CTL register is set, the minimum f_{CKIN} specification is 24 MHz for commercial/industrial models.

⁵ Applies after power-up sequence is complete. See Table 22 and Figure 11 for power-up reset timing.

⁶ Applies when processor is configured in No Boot Mode (BMODE2-0 = b#000).

Figure 10. Clock and Reset Timing

Table 22. Power-Up Reset Timing

Parameter		Min	Max	Unit
<i>Timing Requirement</i>				
$t_{RST_IN_PWR}$	\overline{RESET} Deasserted after the V_{DDINT} , V_{DDEXT} , V_{DDRTC} , and CLKIN Pins are Stable and Within Specification	$3500 \times t_{CKIN}$		ns

In Figure 11, $V_{DD_SUPPLIES}$ is V_{DDINT} , V_{DDEXT} , V_{DDRTC}

Figure 11. Power-Up Reset Timing

Asynchronous Memory Read Cycle Timing

Table 23 and Table 24 on Page 30 and Figure 12 and Figure 13 on Page 30 describe asynchronous memory read cycle operations for synchronous and for asynchronous ARDY.

Table 23. Asynchronous Memory Read Cycle Timing with Synchronous ARDY

Parameter		Min	Max	Unit
<i>Timing Requirements</i>				
t_{SDAT}	DATA15–0 Setup Before CLKOUT	2.1		ns
t_{HDAT}	DATA15–0 Hold After CLKOUT	0.8		ns
t_{SARDY}	ARDY Setup Before the Falling Edge of CLKOUT	4.0		ns
t_{HARDY}	ARDY Hold After the Falling Edge of CLKOUT	0.0		ns
<i>Switching Characteristics</i>				
t_{DO}	Output Delay After CLKOUT ¹		6.0	ns
t_{HO}	Output Hold After CLKOUT ¹	0.8		ns

¹ Output pins include $\overline{AMS3-0}$, $\overline{ABE1-0}$, $\overline{ADDR19-1}$, \overline{AOE} , \overline{ARE} .

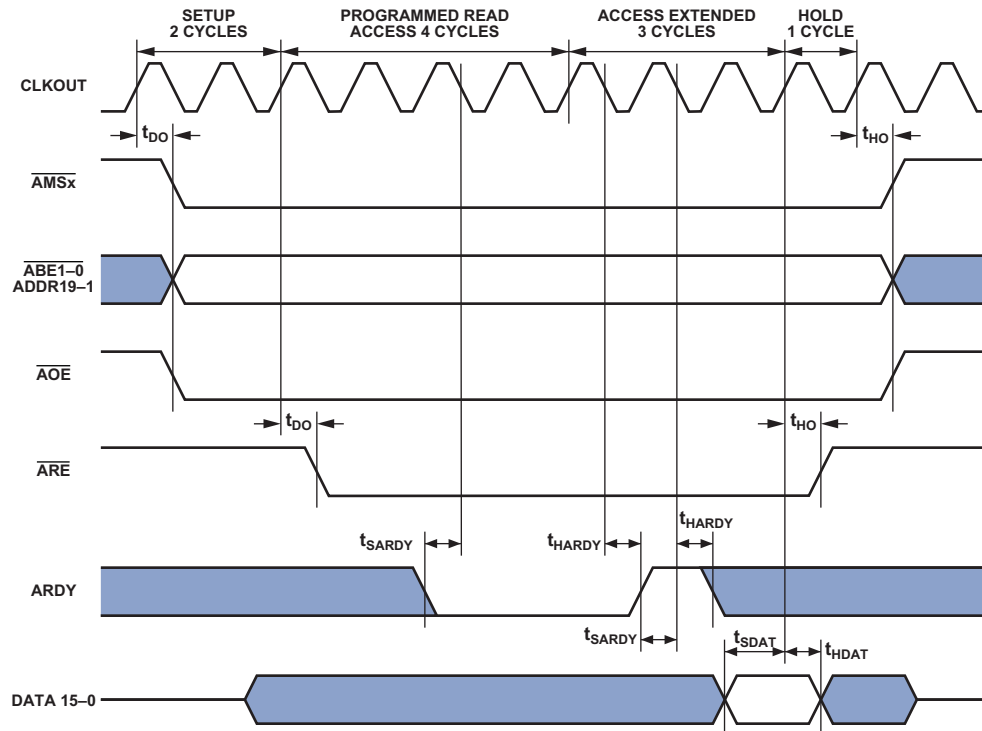

Figure 12. Asynchronous Memory Read Cycle Timing with Synchronous ARDY

ADSP-BF538/ADSP-BF538F

Serial Port Timing

Table 31 through Table 34 on Page 41 and Figure 23 on Page 39 through Figure 26 on Page 41 describe serial port operations.

Table 31. Serial Ports—External Clock

Parameter	Min	Max	Unit
<i>Timing Requirements</i>			
t_{SFSE} TFSx/RFSx Setup Before TSCLKx/RSCLKx (Externally Generated TFSx/RFSx) ¹	3.0		ns
t_{HFSE} TFSx/RFSx Hold After TSCLKx/RSCLKx (Externally Generated TFSx/RFSx) ¹	3.0		ns
t_{SDRE} Receive Data Setup Before RSCLKx ¹	3.0		ns
t_{HDRE} Receive Data Hold After RSCLKx ¹	3.0		ns
t_{SCLKEW} TSCLKx/RSCLKx Width	4.5		ns
t_{SCLKE} TSCLKx/RSCLKx Period	15.0		ns
t_{SUDTE} Start-Up Delay From SPORT Enable To First External TFSx ²	$4.0 \times t_{SCLKE}$		ns
t_{SUDRE} Start-Up Delay From SPORT Enable To First External RFSx ²	$4.0 \times t_{SCLKE}$		ns
<i>Switching Characteristics</i>			
t_{DFSE} TFSx/RFSx Delay After TSCLKx/RSCLKx (Internally Generated TFSx/RFSx) ³		10.0	ns
t_{HOFSE} TFSx/RFSx Hold After TSCLKx/RSCLKx (Internally Generated TFSx/RFSx) ³	0.0		ns
t_{DDTE} Transmit Data Delay After TSCLKx ³		10.0	ns
t_{HDTE} Transmit Data Hold After TSCLKx ³	0.0		ns

¹ Referenced to sample edge.

² Verified in design but untested. After being enabled, the serial port requires external clock pulses—before the first external frame sync edge—to initialize the serial port.

³ Referenced to drive edge.

Table 32. Serial Ports—Internal Clock

Parameter	Min	Max	Unit
<i>Timing Requirements</i>			
t_{SFSI} TFSx/RFSx Setup Before TSCLKx/RSCLKx (Externally Generated TFSx/RFSx) ¹	9.0		ns
t_{HFSI} TFSx/RFSx Hold After TSCLKx/RSCLKx (Externally Generated TFSx/RFSx) ¹	–1.5		ns
t_{SDRI} Receive Data Setup Before RSCLKx ¹	9.0		ns
t_{HDRI} Receive Data Hold After RSCLKx ¹	–1.5		ns
<i>Switching Characteristics</i>			
t_{DFSI} TFSx/RFSx Delay After TSCLKx/RSCLKx (Internally Generated TFSx/RFSx) ²		3.5	ns
t_{HOFSI} TFSx/RFSx Hold After TSCLKx/RSCLKx (Internally Generated TFSx/RFSx) ²	–1.0		ns
t_{DDTI} Transmit Data Delay After TSCLKx ²		3.0	ns
t_{HDTI} Transmit Data Hold After TSCLKx ²	–2.0		ns
t_{SCLKIW} TSCLKx/RSCLKx Width	4.5		ns

¹ Referenced to sample edge.

² Referenced to drive edge.

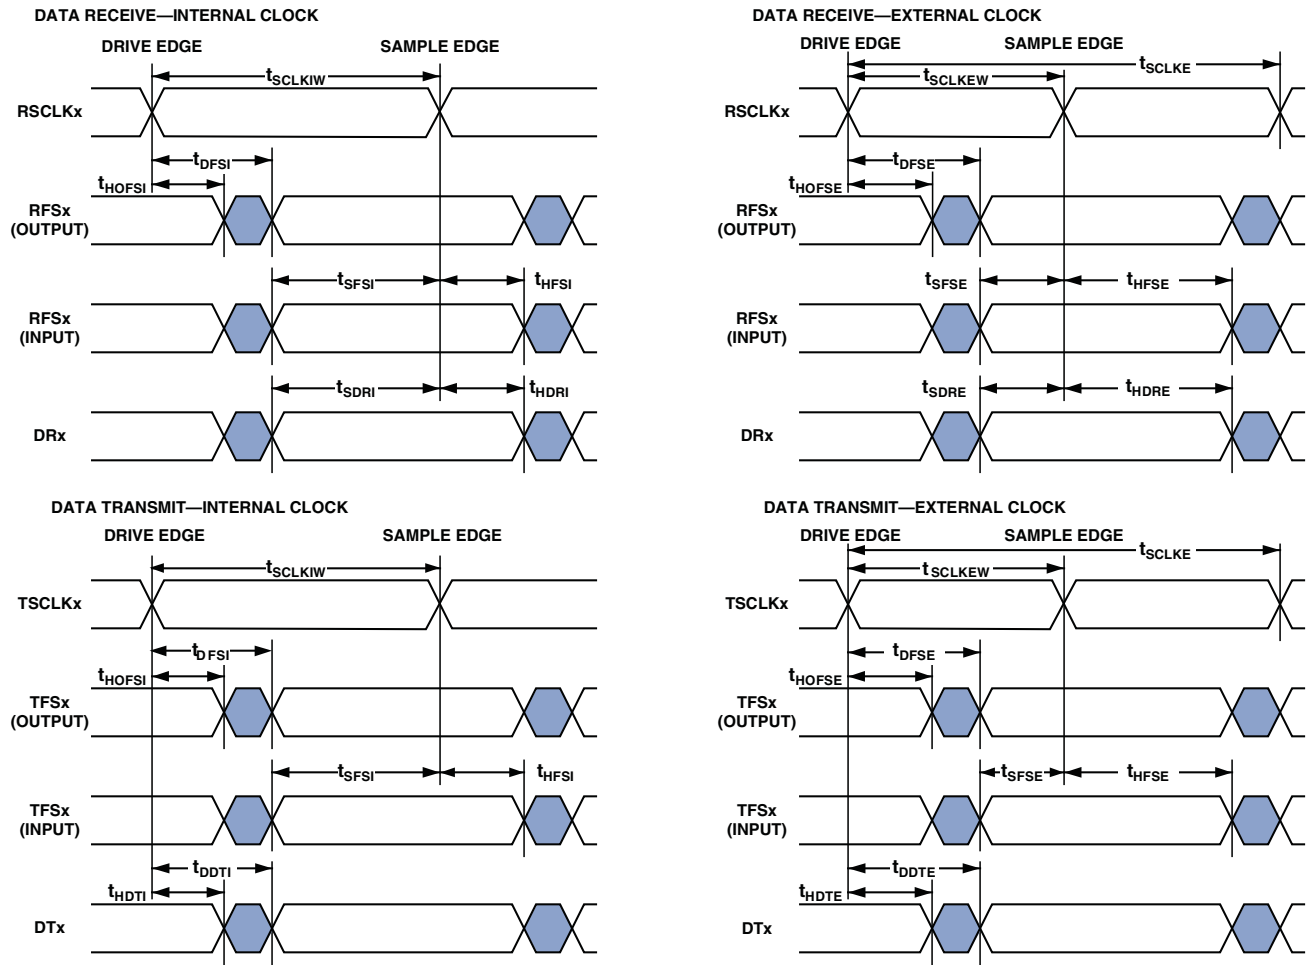

Figure 23. Serial Ports

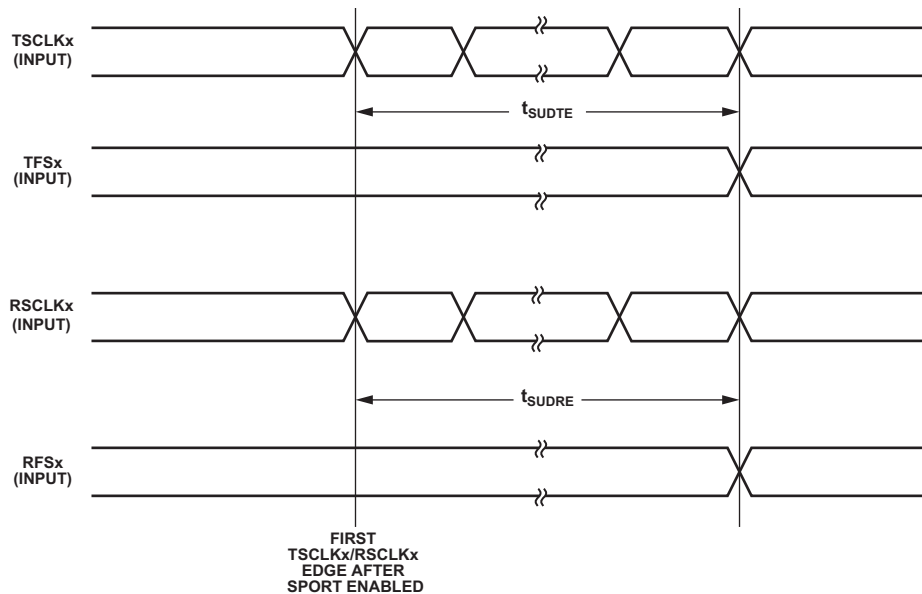

Figure 24. Serial Port Start Up with External Clock and Frame Sync

ADSP-BF538/ADSP-BF538F

Table 33. Serial Ports—Enable and Three-State

Parameter		Min	Max	Unit
<i>Switching Characteristics</i>				
t_{DTENE}	Data Enable Delay from External TSCLKx ¹	0		ns
t_{DDTTE}	Data Disable Delay from External TSCLKx ^{1, 2, 3}		10	ns
t_{DTENI}	Data Enable Delay from Internal TSCLKx ¹	-2		ns
t_{DDTTI}	Data Disable Delay from Internal TSCLKx ^{1, 2, 3}		3	ns

¹Referenced to drive edge.
²Applicable to multichannel mode only.
³TSCLKx is tied to RSCLKx.

Figure 25. Serial Ports—Enable and Three-State

Table 34. External Late Frame Sync

Parameter		Min	Max	Unit
<i>Switching Characteristics</i>				
$t_{DDTLFSE}$	Data Delay from Late External TFSx or External RFSx in multichannel mode, MFD = 0 ^{1,2}		10.0	ns
$t_{DTENLFS}$	Data Enable from Late FS or multichannel mode, MFD = 0 ^{1,2}	0		ns

¹ In multichannel mode, TFSx enable and TFSx valid follow $t_{DTENLFS}$ and $t_{DDTLFSE}$.

² If external RFSx/TFSx setup to RCLKx/TSCLKx > $t_{SCLKE}/2$, then $t_{DDTTE/I}$ and $t_{DTENE/I}$ apply; otherwise $t_{DDTLFSE}$ and $t_{DTENLFS}$ apply.

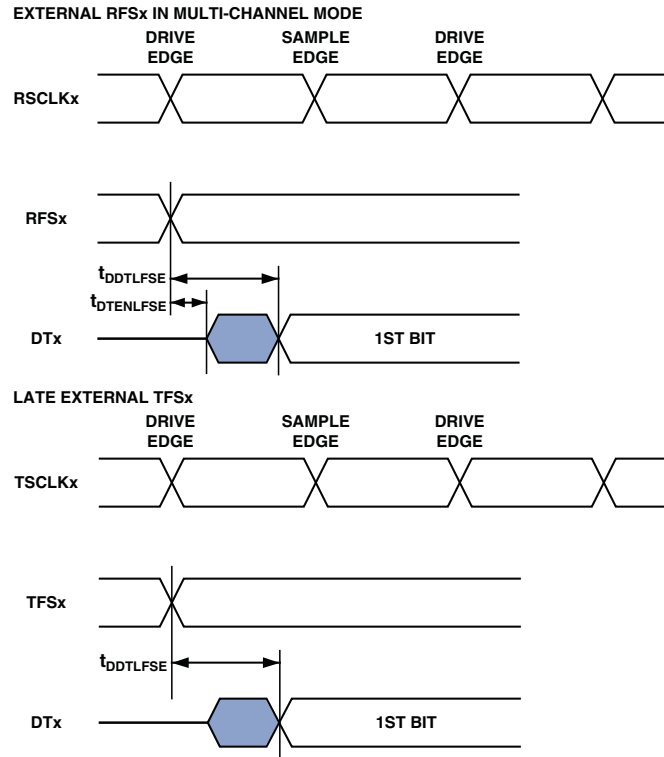

Figure 26. External Late Frame Sync

ADSP-BF538/ADSP-BF538F

Serial Peripheral Interface Ports—Master Timing

Table 35 and Figure 27 describe SPI ports master operations.

Table 35. Serial Peripheral Interface (SPI) Ports—Master Timing

Parameter		Min	Max	Unit
<i>Timing Requirements</i>				
t_{SSPIDM}	Data Input Valid to SCKx Edge (Data Input Setup)	9.0		ns
t_{HSPIDM}	SCKx Sampling Edge to Data Input Invalid	-1.5		ns
<i>Switching Characteristics</i>				
t_{SDSCIM}	$\overline{SPiXSELY}$ Low to First SCKx edge	$2 \times t_{SCLK} - 1.5$		ns
t_{SPICHM}	Serial Clock High Period	$2 \times t_{SCLK} - 1.5$		ns
t_{SPICLM}	Serial Clock Low Period	$2 \times t_{SCLK} - 1.5$		ns
t_{SPICLK}	Serial Clock Period	$4 \times t_{SCLK} - 1.5$		ns
t_{HDSM}	Last SCKx Edge to $\overline{SPiXSELY}$ High	$2 \times t_{SCLK} - 1.5$		ns
t_{SPITDM}	Sequential Transfer Delay	$2 \times t_{SCLK} - 1.5$		ns
$t_{DDSPIDM}$	SCKx Edge to Data Out Valid (Data Out Delay)		5	ns
$t_{HDSPIDM}$	SCKx Edge to Data Out Invalid (Data Out Hold)	-1.0		ns

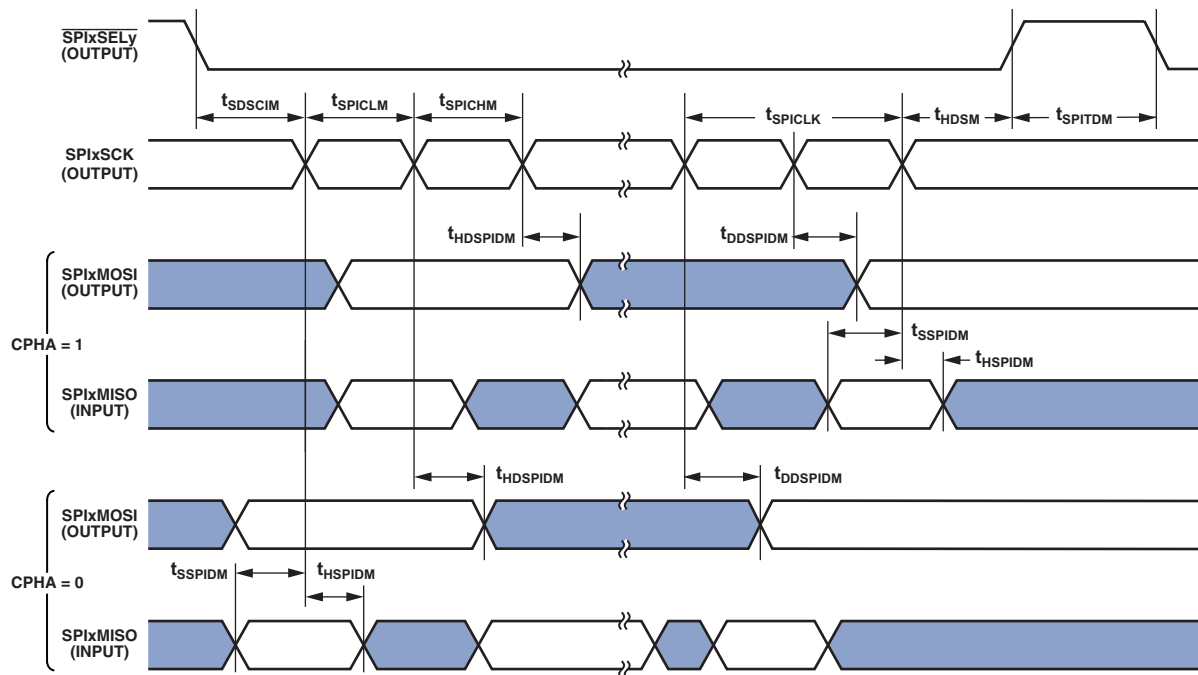

Figure 27. Serial Peripheral Interface (SPI) Ports—Master Timing

Serial Peripheral Interface Ports—Slave Timing

Table 36 and Figure 28 describe SPI ports slave operations.

Table 36. Serial Peripheral Interface (SPI) Ports—Slave Timing

Parameter	Min	Max	Unit
<i>Timing Requirements</i>			
t_{SPICHS} Serial Clock High Period	$2 \times t_{SCLK} - 1.5$		ns
t_{SPICLS} Serial Clock Low Period	$2 \times t_{SCLK} - 1.5$		ns
t_{SPICLK} Serial Clock Period	$4 \times t_{SCLK}$		ns
t_{HDS} Last SCKx Edge to \overline{SPiXSS} Not Asserted	$2 \times t_{SCLK} - 1.5$		ns
t_{SPITDS} Sequential Transfer Delay	$2 \times t_{SCLK} - 1.5$		ns
t_{SDSCI} \overline{SPiXSS} Assertion to First SCKx Edge	$2 \times t_{SCLK} - 1.5$		ns
t_{SSPID} Data Input Valid to SCKx Edge (Data Input Setup)	2.0		ns
t_{HSPID} SCKx Sampling Edge to Data Input Invalid	2.0		ns
<i>Switching Characteristics</i>			
t_{DSOE} \overline{SPiXSS} Assertion to Data Out Active	0	8	ns
t_{DSDHI} \overline{SPiXSS} Deassertion to Data High impedance	0	8	ns
t_{DDSPID} SCKx Edge to Data Out Valid (Data Out Delay)		10	ns
t_{HDSPID} SCKx Edge to Data Out Invalid (Data Out Hold)	0		ns

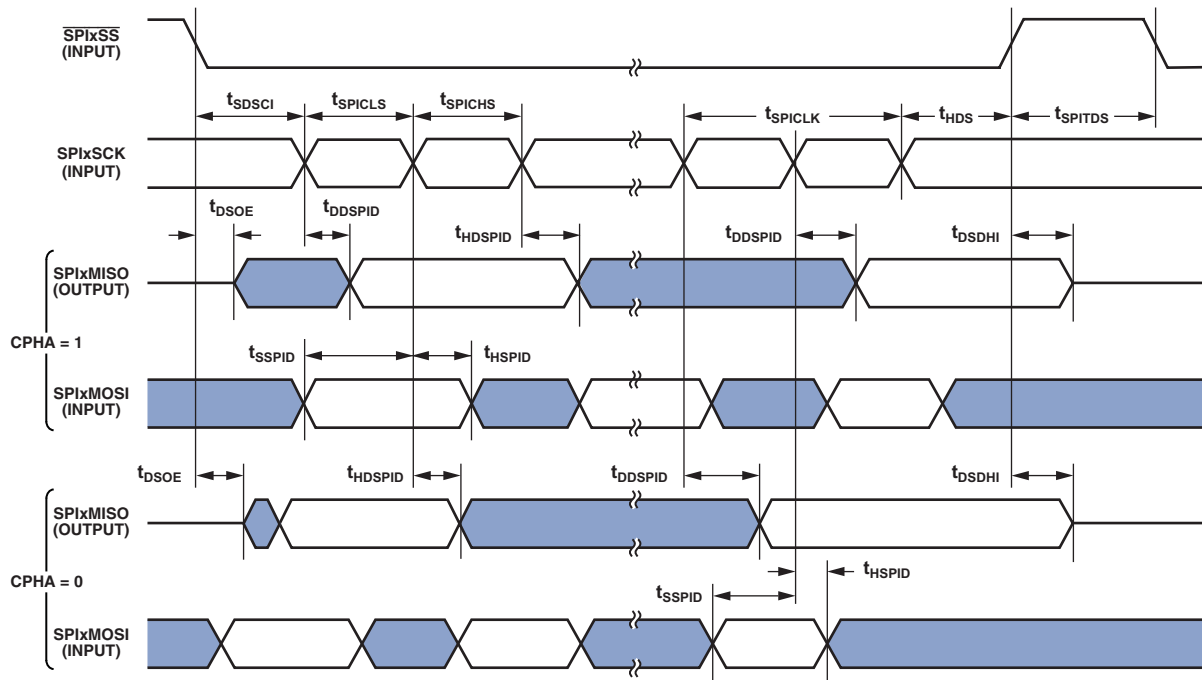

Figure 28. Serial Peripheral Interface (SPI) Ports—Slave Timing

ADSP-BF538/ADSP-BF538F

General-Purpose Port Timing

Table 37 and Figure 29 describe general-purpose operations.

Table 37. General-Purpose Port Timing

Parameter	Min	Max	Unit
<i>Timing Requirement</i>			
t_{WFI} GP Port Pin Input Pulse Width	$t_{SCLK} + 1$		ns
<i>Switching Characteristic</i>			
t_{GPOD} GP Port Pin Output Delay from CLKOUT Low		6	ns

Figure 29. General-Purpose Port Cycle Timing

Timer Clock Timing

Table 38 and Figure 30 describe timer clock timing.

Table 38. Timer Clock Timing

Parameter	Min	Max	Unit
<i>Switching Characteristic</i>			
t_{TODP} Timer Output Update Delay After PPI_CLK High		12	ns

Figure 30. Timer Clock Timing

Timer Cycle Timing

Table 39 and Figure 31 describe timer expired operations. The input signal is asynchronous in “width capture mode” and “external clock mode” and has an absolute maximum input frequency of $(f_{SCLK}/2)$ MHz.

Table 39. Timer Cycle Timing

Parameter		Min	Max	Unit
<i>Timing Characteristics</i>				
t_{WL}	Timer Pulse Width Input Low ¹	$1 \times t_{SCLK}$		ns
t_{WH}	Timer Pulse Width Input High ¹	$1 \times t_{SCLK}$		ns
t_{TIS}	Timer Input Setup Time Before CLKOUT Low ²	6.5		ns
t_{TIH}	Timer Input Hold Time After CLKOUT Low ²	-1		ns
<i>Switching Characteristics</i>				
t_{HTO}	Timer Pulse Width Output	$1 \times t_{SCLK}$	$(2^{32} - 1) \times t_{SCLK}$	ns
t_{TOD}	Timer Output Delay After CLKOUT High		6	ns

¹ The minimum pulse widths apply for TMRx signals in width capture and external clock modes.

² Either a valid setup and hold time or a valid pulse width is sufficient. There is no need to resynchronize timer flag inputs.

Figure 31. Timer Cycle Timing

ADSP-BF538/ADSP-BF538F

Universal Asynchronous Receiver-Transmitter (UART) Ports—Receive and Transmit Timing

For information on the UART port receive and transmit operations, see the *ADSP-BF538 Blackfin Processor Hardware Reference*.

JTAG Test and Emulation Port Timing

Table 40 and Figure 32 describe JTAG port operations.

Table 40. JTAG Port Timing

Parameter	Min	Max	Unit
Timing Requirements			
t_{TCK} TCK Period	20		ns
t_{STAP} TDI, TMS Setup Before TCK High	4		ns
t_{HTAP} TDI, TMS Hold After TCK High	4		ns
t_{SSYS} System Inputs Setup Before TCK High ¹	4		ns
t_{HSYS} System Inputs Hold After TCK High ¹	6		ns
t_{TRSTW} \overline{TRST} Pulse Width ² (Measured in TCK Cycles)	4		TCK
Switching Characteristics			
t_{DIDO} TDO Delay from TCK Low		10	ns
t_{DSYS} System Outputs Delay After TCK Low ^{3,4}	0	12	ns

Figure 32. JTAG Port Timing

OUTPUT DRIVE CURRENTS

Figure 33 through Figure 40 on Page 48 show typical current-voltage characteristics for the output drivers of the ADSP-BF538/ADSP-BF538F processors. The curves represent the current drive capability of the output drivers as a function of output voltage.

TEST CONDITIONS

All timing parameters appearing in this data sheet were measured under the conditions described in this section. Figure 43 shows the measurement point for ac measurements (except output enable/disable). The measurement point V_{MEAS} is 1.5 V for V_{DDEXT} (nominal) = 3.0 V/3.3 V.

Figure 43. Voltage Reference Levels for AC Measurements (Except Output Enable/Disable)

Output Enable Time Measurement

Output pins are considered to be enabled when they have made a transition from a high impedance state to the point when they start driving.

The output enable time t_{ENA} is the interval from the point when a reference signal reaches a high or low voltage level to the point when the output starts driving as shown on the right side of Figure 44, “Output Enable/Disable,” on page 49.

The time $t_{ENA_MEASURED}$ is the interval from when the reference signal switches to when the output voltage reaches $V_{TRIP(high)}$ or $V_{TRIP(low)}$. $V_{TRIP(high)}$ is 2.0 V and $V_{TRIP(low)}$ is 1.0 V for V_{DDEXT} (nominal) = 3.0 V/3.3 V. Time t_{TRIP} is the interval from when the output starts driving to when the output reaches the $V_{TRIP(high)}$ or $V_{TRIP(low)}$ trip voltage.

Time t_{ENA} is calculated as shown in the equation:

$$t_{ENA} = t_{ENA_MEASURED} - t_{TRIP}$$

If multiple pins (such as the data bus) are enabled, the measurement value is that of the first pin to start driving.

Output Disable Time Measurement

Output pins are considered to be disabled when they stop driving, go into a high impedance state, and start to decay from their output high or low voltage. The output disable time t_{DIS} is the difference between $t_{DIS_MEASURED}$ and t_{DECAY} as shown on the left side of Figure 44.

$$t_{DIS} = t_{DIS_MEASURED} - t_{DECAY}$$

The time for the voltage on the bus to decay by ΔV is dependent on the capacitive load C_L and the load current I_L . This decay time can be approximated by the equation:

$$t_{DECAY} = (C_L \Delta V) / I_L$$

The time t_{DECAY} is calculated with test loads C_L and I_L , and with ΔV equal to 0.5 V for V_{DDEXT} (nominal) = 3.0 V/3.3 V.

The time $t_{DIS_MEASURED}$ is the interval from when the reference signal switches, to when the output voltage decays ΔV from the measured output high or output low voltage.

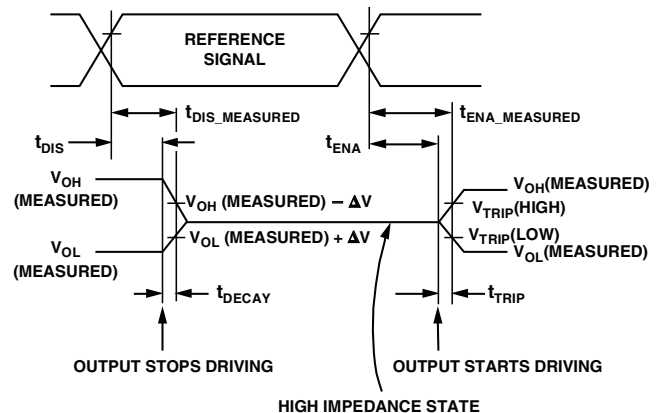

Figure 44. Output Enable/Disable

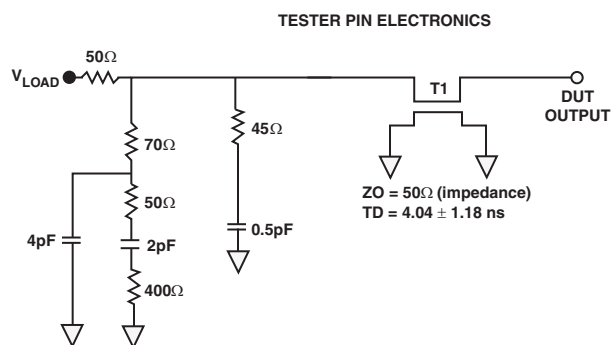

ADSP-BF538/ADSP-BF538F

Example System Hold Time Calculation

To determine the data output hold time in a particular system, first calculate t_{DECAY} using the equation given above. Choose ΔV to be the difference between the ADSP-BF538/ADSP-BF538F processor's output voltage and the input threshold for the device requiring the hold time. C_L is the total bus capacitance (per data line), and I_L is the total leakage or three-state current (per data line). The hold time will be t_{DECAY} plus the various output disable times as specified in the [Timing Specifications on Page 28](#) (for example, t_{DSDAT} for an SDRAM write cycle as shown in [Table 27 on Page 33](#)).

Capacitive Loading

Output delays and holds are based on standard capacitive loads: 30 pF on all pins (see [Figure 45](#)). V_{LOAD} is 1.5 V for V_{DDEXT} (nominal) = 3.0 V/3.3 V. [Figure 46](#) through [Figure 55 on Page 52](#) show how output rise and fall times vary with capacitance. The delay and hold specifications given should be derated by a factor derived from these figures. The graphs in these figures may not be linear outside the ranges shown.

NOTES:
THE WORST CASE TRANSMISSION LINE DELAY IS SHOWN AND CAN BE USED FOR THE OUTPUT TIMING ANALYSIS TO REFLECT THE TRANSMISSION LINE EFFECT AND MUST BE CONSIDERED. THE TRANSMISSION LINE (TD) IS FOR LOAD ONLY AND DOES NOT AFFECT THE DATA SHEET TIMING SPECIFICATIONS.

ANALOG DEVICES RECOMMENDS USING THE IBIS MODEL TIMING FOR A GIVEN SYSTEM REQUIREMENT. IF NECESSARY, A SYSTEM MAY INCORPORATE EXTERNAL DRIVERS TO COMPENSATE FOR ANY TIMING DIFFERENCES.

THERMAL CHARACTERISTICS

To determine the junction temperature on the application printed circuit board use

$$T_J = T_{CASE} + (\Psi_{JT} \times P_D)$$

where:

T_J = junction temperature (°C)

T_{CASE} = case temperature (°C) measured by customer at top center of package.

Ψ_{JT} = from [Table 41](#) or [Table 42](#)

P_D = power dissipation (see [Electrical Characteristics on Page 25](#) for the method to calculate P_D)

Values of θ_{JA} are provided for package comparison and printed circuit board design considerations. θ_{JA} can be used for a first order approximation of T_J by the equation

$$T_J = T_A + (\theta_{JA} \times P_D)$$

where:

T_A = ambient temperature (°C)

Values of θ_{JC} are provided for package comparison and printed circuit board design considerations when an external heatsink is required.

Values of θ_{JB} are provided for package comparison and printed circuit board design considerations.

In [Table 41](#) and [Table 42](#), airflow measurements comply with JEDEC standards JESD51-2 and JESD51-6, and the junction-to-board measurement complies with JESD51-8. The junction-to-case measurement complies with MIL-STD-883 (Method 1012.1). All measurements use a 2S2P JEDEC test board.

Model ¹	Temperature Range ²	Instruction Rate (Max)	Flash Memory	Operating Voltage (Nominal)	Package Description	Package Option
ADSP-BF538BBCZ-4A	–40°C to +85°C	400 MHz	N/A	1.2 V internal, 2.5 V or 3.3 V I/O	316-Ball CSP_BGA	BC-316-2
ADSP-BF538BBCZ-5A	–40°C to +85°C	533 MHz	N/A	1.25 V internal, 2.5 V or 3.3 V I/O	316-Ball CSP_BGA	BC-316-2
ADSP-BF538BBCZ-4F8	–40°C to +85°C	400 MHz	8M bit	1.2 V internal, 3.0 V or 3.3 V I/O	316-Ball CSP_BGA	BC-316-2
ADSP-BF538BBCZ-5F8	–40°C to +85°C	533 MHz	8M bit	1.25 V internal, 3.0 V or 3.3 V I/O	316-Ball CSP_BGA	BC-316-2

¹Z = RoHS compliant part.

²Referenced temperature is ambient temperature.
