CONVENTIONS

Arial Bold   Designates headings, figure captions, and table captions.

Blue   Designates hyperlinks (PDF copy only).

Italics   Designates emphasis or caution related to nearby information. Italics is also used to designate variables, refer to related documents, and to differentiate terms from other common words (e.g., "During refresh cycles, the *a* and *ad* buses may not have the same address during the address phase of the *ad* bus cycle." "The *hold* latency time [time between the *hold* and hlda] depends on the current processor activity when the hold is received.").

ACRONYMS AND ABBREVIATIONS

AMD	Advanced Micro Devices
BIC	Bus Interface and Control
CDRAM	Count for Dynamic RAM
CSC	Chip Selects and Control
DA	Disable Address
DMA	Direct Memory Access
EOI	End of Interrupt
ISR	Interrupt Service Routine
LMCS	Low-Memory Chip Select
LQFP	Low-Profile Quad Flat Package
MC	Maximum Count
MDRAM	Memory Partition for Dynamic RAM
MILES™	Managed IC Lifetime Extension System
MMCS	Midrange Memory Chip Select
NMI	nonmaskable interrupt
PCB	peripheral control block
PIO	programmable I/O
PLL	phase-lock-loop
POR	power-on reset
PQFP	Plastic Quad Flat Package
PSRAM	Pseudo-Static RAM
RCU	Refresh Control Unit
RoHS	Restriction of Hazardous Substances
SFNM	Special Fully Nested mode
UART	Universal Asynchronous Receiver-Transmitter
UMCS	Upper Memory Chip Select

1. Introduction

The IA186ER/IA188ER is a form, fit, and function replacement for the original Advanced Micro Devices Am186ER/Am188ER family of microcontrollers. Innovasic produces replacement ICs using its MILES^{TM}, or Managed IC Lifetime Extension System cloning technology. This technology produces replacement ICs far more complex than "emulation" while ensuring they are compatible with the original IC. MILES^{TM} captures the design of a clone so it can be produced even as silicon technology advances. MILES^{TM} also verifies the clone against the original IC so that even the "undocumented features" are duplicated.

1.1 General Description

The IA186ER/IA188ER family of microcontrollers replaces obsolete Am186ER/188ER devices, allowing customers to retain existing board designs, software compilers/assemblers and emulation tools, thereby avoiding expensive redesign efforts.

The IA186ER/IA188ER microcontrollers are an upgrade for the 80C186/80C188 microcontroller designs, with integrated peripherals to provide increased functionality and reduce system costs. The Innovasic devices are created to satisfy requirements of embedded products designed for telecommunications, office automation and storage, and industrial controls.

1.2 Features
- Pin-for-pin compatible with Am186ER/Am188ER devices
- All features are retained, including:
  - A phase-lock loop (PLL) allowing same crystal/system clock frequency
  - 8086/8088 instruction set with additional 186 instruction set extensions
  - Programmable interrupt controller
  - Two Direct Memory Access (DMA) channels
  - Three 16-bit timers
  - Internal 32K bytes of Memory
  - Programmable chip select logic and wait-state generator
  - Dedicated watchdog timer
  - Independent asynchronous serial port (UART)
    - DMA capability
    - Hardware flow control
    - 7-, 8-, or 9-bit data capability
- Synchronous Serial Port
  - Half duplex bidirectional data transfer
- Up to 32 programmable I/O pins (PIO)
- Pseudo-static/dynamic RAM controller
- Fully static CMOS design
- 50 MHz operation at industrial operating conditions
- +3.3 VDC power supply
- -40C to +85C Operating Temperature

2. Packaging, Pin Descriptions, and Physical Dimensions

Information on the packages and pin descriptions for the IA186ER and the IA188ER is provided separately. Refer to sections, figures, and tables for information on the device of interest.

Innovasic's part number for these devices is marked as "18x" to indicate the same device will be ordered for the 186 and 188 versions of each particular package style (See Section 8). Please refer to this data sheet for specific use of the pins for the 186 and 188 versions. Please also note that the data bus width of the IA18xER is selectable between 16-bit (IA186ER) or 8-bit (IA188ER) upon powerup. For 8-bit operation tie the whb_n pin to ground. Reference pin descriptions appropriate for the selected strapping option.

2.1 Packages and Pinouts

The Innovasic IA186ER and IA188ER microcontroller is available in the following packages:

- 100-Pin Low-Profile Quad Flat Package (LQFP), equivalent to original TQFP package
- 100-Pin Plastic Quad Flat Package (PQFP), equivalent to original PQFP package

2.1.6   PQFP Physical Dimensions

The physical dimensions for the PQFP are as shown in Figure 6.

Legend						
	Millimeter			Inch		
Symbol	Min	Nom	Max	Min	Nom	Max
A	–	–	3.40	–	–	0.134
A_1	0.25	–	–	0.010	–	–
A_2	2.73	2.85	2.97	0.107	0.112	0.117
B	0.25	0.30	0.38	0.010	0.012	0.015
C	0.13	0.15	0.23	0.005	0.006	0.009
D	23.00	23.20	23.40	0.906	0.913	0.921
D_1	19.90	20.00	20.10	0.783	0.787	0.791
E	17.00	17.20	17.40	0.669	0.677	0.685
E_1	13.90	14.00	14.10	0.547	0.551	0.555
e	0.65 BSC.			0.026 BSC.		
L	0.73	0.88	1.03	0.029	0.035	0.041
L_1	1.60 BSC.			0.063 BSC.		
Y	–	–	0.10	–	–	0.004
θ	0°	–	7°	0°	–	7°

Notes:
1. Dimensions D_1 and E_1 do not include mold protrusion, but mold mismatch is included. Allowable protrusion is 0.25mm/0.010″ per side.
2. Dimension B does not include Dambar protrusion. Allowable protrusion is 0.08mm/0.003″ total in excess of the B dimension at maximum material condition. Dambar cannot be located on the lower radius or the foot.
3. Controlling dimension: millimeter.

2.2   Pin Descriptions

2.2.1   a19/pio9, a18/pio8, a17/pio7, a16–a0—Address Bus (synchronous outputs with tristate)

These pins are the system's source of non-multiplexed I/O or memory addresses and occur one half clkouta cycle before the multiplexed address/data bus (ad15–ad0 for the IA186ER or ao15–ao8 and ad7–ad0 for the IA188ER). The address bus is tristated during a bus hold or reset.

2.2.2   ad15–ad8 (IA186ER)—Address/data bus (level-sensitive synchronous inouts with tristate)

These pins are the system's source of time-multiplexed I/O or memory addresses and data. The address function of these pins can be disabled (see bhe_n/aden_n pin description).   If the address function of these pins is enabled, the address will be present on this bus during t_1 of the bus cycle and data will be present during t_2, t_3, and t_4 of the same bus cycle.

If whb_n is not active, these pins are tristated during t_2, t_3, and t_4 of the bus cycle.

The address/data bus is tristated during a bus hold or reset.

These pins can be used to load the internal Reset Configuration register (RESCON, offset 0F6h) with configuration data during a power-on reset (POR).

2.2.3   ad7–ad0—Address/Data bus (level-sensitive synchronous inouts with tristate)

These pins are the system's source of time-multiplexed low-order byte of the addresses for I/O or memory and 8-bit data. The low-order address byte will be present on this bus during t_1 of the bus cycle and the 8-bit data will be present during t_2, t_3, and t_4 of the same bus cycle.

The address function of these pins can be disabled (see bhe_n/aden_n pin description).

If wlb_n (IA186ER) is not active, these pins are tristated during t_2, t_3, and t_4 of the bus cycle.
The address/data bus is tristated during a bus hold or reset.

2.2.4   ao15–ao8 (IA188ER)—Address-only bus (level-sensitive synchronous outputs with tristate)

The address-only bus will contain valid high-order address bits during the bus cycle (t_1, t_2, t_3, and t_4) if the bus is enabled.

These pins are combined with ad7–ad0 to complete the multiplexed address bus and are tristated during a bus hold or reset condition.

Page 30 of 146

http://www.innovasic.com
Customer Support:
1-888-824-4184

2.2.5   ale—Address Latch Enable (synchronous output)

This signal indicates the presence of an address on the address/data bus (ad15–ad0 for the IA186ER or ao15–ao8 and ad7–ad0 for the IA188ER), which is guaranteed to be valid on the falling edge of ale.

2.2.6   ardy—Asynchronous Ready (level-sensitive asynchronous input)

This asynchronous signal provides an indication to the microcontroller that the addressed I/O device or memory space will complete a data transfer. This active high signal is asynchronous with respect to clkouta and if the falling edge of ardy is not synchronized to clkouta, an additional clock cycle may be added

Signal ardy should be tied high to maintain a permanent assertion of the ready condition. On the other hand, if the ardy signal is not used by the system it should be tied low, which passes control to the srdy signal.

2.2.7   bhe_n/aden_n (IA186ER)—Bus High Enable (synchronous output with tristate)/Address Enable (input with internal pull-up)

The bhe_n and address bit ad0 or a0 inform the system which bytes of the data bus (upper, lower, or both) are involved in the current memory access bus cycle as shown Table 9.

Table 9. Bus Cycle Types for bhe_n and ad0

bhe_n	ad0	Type of Bus Cycle
0	0	Word Transfer
0	1	High-Byte Transfer (Bits [15–8])
1	0	Low-Byte Transfer (Bits [7–0])
1	1	Refresh

The bhe_n does not require latching and during bus hold and reset is tristated. It is asserted during t_1 and remains so through t_3 and t_w.

The high- and low-byte write enable functions of bhe_n and ad0 are performed by whb_n and wlb_n, respectively.

When using the *ad* bus, DRAM refresh cycles are indicated by bhe_n/aden_n and ad0 both being high. During refresh cycles the *a* and *ad* buses may not have the same address during the address phase of the *ad* bus cycle necessitating the use of ad0 as a determinant for the refresh cycle rather than a0.

An additional signal is used for Pseudo-Static RAM (PSRAM) refreshes (see mcs3_n/rfsh_n pin description).

There is a weak internal pull-up on bhe_n/aden_n obviating the need for an external pull-up and reducing power consumption.

1-888-824-4184

Holding aden_n high or letting it float during POR passes control of the address function of the *ad* bus (ad15–ad0) during LCS and UCS bus cycles from aden_n to the Disable Address (DA) bit in Low-Memory Chip Select (LMCS) and Upper Memory Chip Select (UMCS) registers. When the address function is selected, the memory address is placed on the a19–a0 pins.

Holding aden_n low during POR, both the address and data are driven onto the *ad* bus independently of the DA bit setting. This pin is normally sampled one clock cycle after the rising edge of res_n.

2.2.8   clkouta—Clock Output A (synchronous output)

This pin is the internal clock output to the system. Bits [9–8] and Bits [2–0] of the Power-Save Control register (PDCON) control the output of this pin, which may be tristated, output the internal processor frequency (divide by two, x1 or x4), or output the power save frequency (internal processor frequency after divisor). The clkouta can be used as a full-speed clock source in power-save mode. The AC timing specifications that are clock-related refer to clkouta, which remains active during reset and hold conditions.

2.2.9   clkoutb—Clock Output B (synchronous output)

This pin is an additional clock output to the system. Bits [11–10] and [2–0] of the Power-Save Control register (PDCON) control the output of this pin, which may be tristated, internal processor frequency (divide by two, x1 or x4), or may output the power-save frequency (internal processor frequency after divisor). The clkoutb remains active during reset and hold conditions.

2.2.10   den_n/pio5—Data Enable Strobe (synchronous output with tristate)

This pin provides an output enable to an external bus data bus transmitter or receiver. This signal is asserted during I/O, memory, and interrupt acknowledge processes and is deasserted when dt/r_n undergoes a change of state. It is tristated for a bus hold or reset.

2.2.11   drq1/pio13–drq0/pio12—DMA Requests (synchronous level-sensitive inputs)

An external device that is ready for DMA channel 1 or 0 to carry out a transfer indicates to the microcontroller this readiness on these pins. They are level triggered, internally synchronized, not latched, and must remain asserted until handled.

2.2.12   dt/r_n/pio4—Data Transmit or Receive (synchronous output with tristate)

The microcontroller transmits data when dt/r_n is set high and receives data when this pin is asserted low. It floats during a reset or bus hold condition.

2.2.13   gnd—Ground

Six or seven pins, depending on package, connect the microcontroller to the system ground.

Innovasic®

1-888-824-4184**

2.2.14 hlda—Bus Hold Acknowledge (synchronous output)

This pin is set high to signal the system that the microcontroller has ceded control of the local bus, in response to a high on the hold signal by an external bus master, after the microcontroller has completed the current bus cycle. The assertion of hlda is accompanied by the tristating of den_n, rd_n, wr_n, s2_n–s0_n, ad15–ad0, s6, a19–a0, bhe_n, whb_n, wlb_n, and dt/r_n, followed by the driving high of the chip selects ucs_n, lcs_n, mcs3_n–mcs0_n, pcs6_n–pcs5_n, and pcs3_n–pcs0_n. The external bus master releases control of the local bus by the deassertion of hold that in turn induces the microcontroller to deassert the hlda. The microcontroller can take control of the bus if necessary (to execute a refresh for example), by deasserting hlda without the bus master first deasserting hold. This requires that the external bus master be able to deassert hold to permit the microcontroller to access the bus.

2.2.15 hold—Bus Hold Request (synchronous level-sensitive input)

This pin is set high to signal the microcontroller that the system requires control of the local bus.

The *hold* latency time (time between the *hold* and hlda) depends on the current processor activity when the hold is received. A hold request is second only to a DRAM or PSRAM refresh request in priority of processor activity requests. If a hold request is received at the moment a DMA transfer starts, the hold latency can be up to 4 bus cycles. (This happens only on the IA186ER when a word transfer is taking place from an odd to an odd address.) This means that the latency may be 16 clock cycles without wait states. Furthermore, if lock transfers are being performed, then the latency is increased during the locked transfer.

2.2.16 int0—Maskable Interrupt Request 0 (asynchronous input)

The int0 pin provides an indication that an interrupt request has occurred, and provided that int0 is not masked, program execution will continue at the location specified by the INT0 vector in the interrupt vector table.   Although interrupt requests are asynchronous, they are synchronized internally and may be edge- or level-triggered. To ensure that it is recognized, the assertion of the interrupt request must be maintained until it is handled.

2.2.17 int1/select_n—Maskable Interrupt Request 1/Slave Select (both are asynchronous inputs)

The int1 pin provides an indication that an interrupt request has occurred, and provided that int1 is not masked, program execution will continue at the location specified by the int1 vector in the interrupt vector table.   Although interrupt requests are asynchronous, they are synchronized internally and may be edge- or level-triggered. To ensure that it is recognized, the assertion of the interrupt request must be maintained until it is handled.

The select_n pin provides an indication to the microcontroller that an interrupt type has been placed on the address/data bus when the internal Interrupt Control Unit is slaved to an external

interrupt controller. Before this can occur, however, the int0 pin must have already indicated an interrupt request.

2.2.18 int2/inta0_n/pio31—Maskable Interrupt Request 2 (asynchronous input)/Interrupt Acknowledge 0 (synchronous output)

The int2 pin provides an indication that an interrupt request has occurred, and provided that int2 is not masked, program execution will continue at the location specified by the int2 vector in the interrupt vector table. Although interrupt requests are asynchronous, they are synchronized internally and may be edge- or level-triggered. To ensure that it is recognized, the assertion of the interrupt request must be maintained until it is handled. When int0 is configured for cascade mode, int2 changes its function to inta0_n.

The inta0_n function indicates to the system that the microcontroller requires an interrupt type in response to the interrupt request int0 when the microcontroller's Interrupt Control Unit is in cascade mode. The peripheral device that issued the interrupt must provide the interrupt type.

2.2.19 int3/inta1_n/irq—Maskable Interrupt Request 3 (asynchronous input)/Interrupt Acknowledge 1 (synchronous output)/Interrupt Request (synchronous output)

The int3 pin provides an indication that an interrupt request has occurred. If int3 is not masked, program execution will continue at the location specified by the int3 vector in the interrupt vector table. Although interrupt requests are asynchronous, they are synchronized internally and may be edge- or level-triggered. To ensure that it is recognized, the assertion of the interrupt request must be maintained until it is handled. When int1 is configured to be in cascade mode, int3 changes its function to inta1_n.

The inta1_n function indicates to the system that the microcontroller requires an interrupt type in response to the interrupt request int1 when the microcontroller's Interrupt Control Unit is in cascade mode. The peripheral device that issued the interrupt must provide the interrupt type.

Irq allows the microcontroller to output an interrupt request to the external master interrupt controller when the Interrupt Control Unit of the microcontroller is in slave mode.

2.2.20 int4/pio30—Maskable Interrupt Request 4 (asynchronous input)

The int4 pin provides an indication that an interrupt request has occurred, and provided that int4 is not masked, program execution will continue at the location specified by the int4 vector in the interrupt vector table. Although interrupt requests are asynchronous, they are synchronized internally and may be edge- or level-triggered. To ensure that it is recognized, the assertion of the interrupt request must be maintained until it is handled.

2.2.21   lcs_n/once0_n—Lower Memory Chip Select (synchronous output with internal pull-up)/ONCE Mode Request (input)

The lcs_n pin provides an indication that a memory access is occurring to the lower memory block. The size of the Lower Memory Block and its base address are programmable, with the size adjustable up to 512 Kbytes. The lcs_n pin is held high during bus hold.

The once0_n pin (ONCE – ON Circuit Emulation) and its companion pin, once1_n, define the microcontroller mode during reset. These two pins are sampled on the rising edge of res_n and if both are asserted low the microcontroller starts in ONCE mode, else it starts normally. In ONCE mode, all pins are tristated and remain so until a subsequent reset. To prevent the microcontroller from entering ONCE mode inadvertently, this pin has a weak pull-up that is only present during reset. This pin is not tristated during bus hold.

2.2.22   mcs2_n—mcs0_n (pio24, pio15, pio 14)—Midrange Memory Chip Selects (synchronous outputs with internal pull-up)

The mcs2_n and mcs0_n pins provide an indication that a memory access is in progress to the first, second or third midrange memory block. The size of the Midrange Memory Blocks and its base addresses are programmable. The mcs2_n – mcs0_n are held high during bus hold and have weak pull-ups that are only present during reset.

2.2.23   mcs3_n/rfsh_n/pio25—Midrange Memory Chip Select (synchronous output with internal pull-up)/Automatic Refresh (synchronous output)

The mcs3_n pin provides an indication that a memory access is in progress to the fourth region of the midrange memory block. The size of the Midrange Memory Block and its base address are programmable. The mcs3_n is held high during bus hold and has a weak pull-up that is present only during reset.

The rfsh_n signal is timed for auto refresh to PSRAM or DRAM devices. The refresh pulse is output only when the PSRAM or DRAM mode bit is set (EDRAM register Bit [15]). This pulse is of 1.5 clock-pulse duration with the rest of the refresh cycle made up of a deassertion period such that the overall refresh time is met. This pin is not tristated during a bus hold.

2.2.24   nmi—Nonmaskable Interrupt (synchronous edge-sensitive input)

Unlike int4 – int0, this is the highest priority interrupt signal and cannot be masked. Upon the assertion of this interrupt (transition from Low to High), program execution is transferred to the nonmaskable interrupt vector in the interrupt vector table and this interrupt is initiated at the next instruction boundary. For recognition to be assured, the nmi pin must be held high for at least a clkouta period so that the transition from low to high is latched and synchronized internally. The interrupt will begin at the next instruction boundary.

The nmi is not involved in the priority resolution process that deals with the maskable interrupts and does not have an associated interrupt flag. This allows for a new nmi request to interrupt an nmi service routine that is already underway. When an interrupt is taken by the processor the interrupt flag IF is cleared, disabling the maskable interrupts. If the maskable interrupts are reenabled during the nmi service routine (e.g., by use of STI instruction), the priority resolution of maskable interrupts will be unaffected by the servicing of the non-maskable interrupt (NMI).

> *Note: For this reason, it is strongly recommended that the NMI interrupt service routine does not enable the maskable interrupts.*

2.2.25 pcs3_n–pcs0_n (pio19–pio16)—Peripheral Chip Selects 3–0 (synchronous outputs)

The pcs3_n–pcs0_n pins provide an indication that a memory access is underway for the corresponding region of the peripheral memory block (I/O or memory address space). The base address of the peripheral memory block is programmable. The pins are held high during both bus hold and reset. These outputs are asserted with the *ad* address bus over a 256-byte range each.

2.2.26 pcs5_n/a1/pio3—Peripheral Chip Select 5 (synchronous output)/Latched Address Bit 1 (synchronous output)

The pcs5_n signal provides an indication that a memory access is underway for the sixth region of the peripheral memory block (I/O or memory address space). The base address of the peripheral memory block is programmable. The pcs5_n is held high during both bus hold and reset. This output is asserted with the *ad* address bus over a 256-byte range.

This a1 pin provides an internally latched address bit 1 to the system when the EX bit (Bit [7]) in the mcs_n and pcs_n auxiliary (MPCS) register is 0. It retains its previously latched value during a bus hold.

2.2.27 pcs6_n/a2/pio2—Peripheral Chip Select 6 (synchronous output)/latched Address Bit 2 (synchronous output)

The pcs6_n signal provides an indication that a memory access is underway for the seventh region of the peripheral memory block (I/O or memory address space). The base address of the peripheral memory block is programmable. The pcs6_n is held high during both bus hold and reset. This output is asserted with the *ad* address bus over a 256-byte range.

The a2 pin provides an internally latched address bit [2] to the system when the EX bit (Bit [7]) in the mcs_n and pcs_n auxiliary (MPCS) register is 0. It retains its previously latched value during a bus hold.

1-888-824-4184

2.2.28   pio31–pio0—Programmable I/O Pins (asynchronous input/output open-drain)

There are 32 individually programmable I/O pins provided (see Table 15, Default Status of PIO Pins at Reset).

2.2.29   rd_n—Read strobe (synchronous output with tristate)

The rd_n pin provides an indication to the system that a memory or I/O read cycle is underway. It will not be asserted before the *ad* bus is floated during the address to data transition. The rd_n pin is tristated during bus hold.

2.2.30   res_n—Reset (asynchronous level-sensitive input)

The res_n pin forces a reset of the microcontroller. Its Schmitt trigger allows POR generation via an RC network. When this signal is asserted, the microcontroller immediately terminates its present activity, clears its internal logic, and transfers CPU control to the reset address, FFFF0h.

The res_n must be asserted for at least 1 ms. Because it is synchronized internally it may be asserted asynchronously to clkouta. Furthermore, v_{cc} must be within specification and clkouta must be stable for more than four of its clock periods for the period that res_n is asserted.

The microcontroller starts to fetch instructions 6.5 clkouta clock periods after the deassertion of res_n.

2.2.31   rfsh2_n/aden_n (IA188ER)—Refresh 2 (synchronous output with tristate)/Address Enable (input with internal pull-up)

The rfsh2_n indicates that a DRAM refresh cycle is being performed when it is asserted low. However, this is not valid in PSRAM mode where mcs3_n/rfsh_n is used instead.

If the aden_n pin is held high during POR, the *ad* bus (ao15–ao8 and ad7–ad0 for the IA188ER) is controlled during the address portion of the lcs and ucs bus cycles by the DA bit (Bit [7]) in the lcs and ucs registers. If the DA bit is 1, the address is accessed on the a19–a0 pins, reducing power consumption. The weak pull-up on this pin obviates the necessity of an external pull-up.

If the aden_n pin is held low during POR, the *ad* bus is used for both addresses and data without regard for the setting of the DA bits. The rfsh2_n/aden_n is sampled one crystal clock cycle after the rising edge of res_n and is tristated during bus holds and ONCE mode.

2.2.32   rxd/pio28—Receive Data (asynchronous input)

This signal connects asynchronous serial receive data from the system to the asynchronous serial port.

1-888-824-4184

2.2.33 s0_n, s1_n (imdis_n), s0_n (sren_n) —Bus Cycle Status (synchronous outputs with tristate)

These three signals inform the system of the type of bus cycle in progress. The s2_n may be used to indicate whether the current access is to memory or I/O, and s1_n may be used to indicate whether data is being transmitted or received. These signals are tristated during bus hold and hold acknowledge. The coding for these pins is presented in Table 10.

imdis_n: Internal Memory Disable (input, pullup); if low during reset, internal memory is disabled.

sren_n: Show Read Enable (input, pullup); if low during reset, reads from internal memory are driven on the external address/data bus.

Table 10. Bus Cycle Types for s2_n, s1_n, and s0_n

s2_n	s1_n	s0_n	Bus Cycle
0	0	0	Interrupt acknowledge
0	0	1	Read data from I/O
0	1	0	Write data to I/O
0	1	1	Halt
1	0	0	Instruction fetch
1	0	1	Read data from memory
1	1	0	Write data to memory
1	1	1	None (passive)

2.2.34 s6/clksel1_n/pio29—Bus Cycle Status Bit 6 (synchronous output)/Clock Divide by 2 (input with internal pull-up)

The s6 signal is high during the second and remaining cycle periods (i.e., $t_2 - t_{4)}$, indicating that a DMA-initiated bus cycle is underway. The s6 is tristated during bus hold or reset.

Combined with uzi_n/clksel2_n to select clock mode. If low, input clock is divided by two and the PLL is disabled. Default, because of pull-ups, is for x4 clock mode. This pin is sampled on the rise of reset.

> *Note: If this pin is used as pio29 and configured as an input, care should be taken that it is not driven low during POR.*

Because this pin has an internal pull-up, it is not necessary to drive the pin high even though it defaults to an input PIO.

2.2.35   sclk/pio20 —Serial Clock (synchronous outputs with tristate)

Because this pin provides a slave device with a synchronous serial clock it permits synchronization of the transmit and receive data exchanges between the slave and the microcontroller. The sclk is the result of dividing the internal clock by 2, 4, 8, or 16, depending on the contents of the Synchronous Serial Control (SSC) register Bits [5–4]. Accessing either the SSR or SSD registers activates the sclk for eight cycles. When sclk is not active, the microcontroller holds it high.

2.2.36   sdata/pio21 —Serial Data (synchronous inout)

The sdata pin connects a slave device to synchronous serial transmit and receive data. The last value is retained on this pin when it is inactive.

2.2.37   sden1/pio23 – sden0/pio22 —Serial Data Enables (synchronous outputs with tristate)

The sden1–sden0 pins facilitate the transfer of data on ports 1 and 0 of the Synchronous Serial Interface (SSI). Either sden1 or sden0 is asserted by the microcontroller at the start of the data transfer and is de-asserted when the transfer is completed. These pins are held low by the microcontroller when they are inactive.

2.2.38   srdy/pio6—Synchronous Ready (synchronous level-sensitive input)

This signal is an active high input synchronized to clkouta and indicates to the microcontroller that a data transfer will be completed by the addressed memory space or I/O device.

In contrast to the Asynchronous Ready (ardy), which requires internal synchronization, srdy permits easier system timing because it already synchronized. Tying srdy high will always assert this ready condition. Tying it low will give control to ardy.

2.2.39   tmrin0/pio11—Timer Input 0 (synchronous edge-sensitive input)

This signal may be either a clock or control signal for the internal Timer 0. The timer is incremented by the microcontroller after it synchronizes a rising edge of tmrin0. When not used, tmrin0 must be tied high, or when used as pio11, it is pulled up internally.

2.2.40   tmrin1/pio0—Timer Input 1 (synchronous edge-sensitive input)

This signal may be either a clock or control signal for the internal Timer 1. The timer is incremented by the microcontroller after it synchronizes a rising edge of tmrin1. When not used, tmrin1 must be tied high, or when used as pio0, it is pulled up internally.

2.2.41 tmrout0/pio10—Timer Output 0 (synchronous output)

This signal provides the system with a single pulse or a continuous waveform with a programmable duty cycle. It is tristated during a bus hold or reset.

2.2.42 tmrout1/pio1—Timer Output 1 (synchronous output)

This signal provides the system with a single pulse or a continuous waveform with a programmable duty cycle. It is tristated during a bus hold or reset.

2.2.43 txd/pio27—Transmit Data (asynchronous output)

This pin provides the system with asynchronous serial transmit data from the serial port.

2.2.44 ucs_n/once1_n—Upper Memory Chip Select (synchronous output)/ONCE Mode Request 1 (input with internal pull-up)

The ucs_n pin provides an indication that a memory access is in progress to the upper memory block. The size of the Upper Memory Block and its base address are programmable, with the size adjustable up to 512 Kbytes. The ucs_n pin is held high during bus hold.

After power-on-reset, ucs_n is asserted low and program execution begins at FFFF0h. Its default configuration is a 64-Kbyte memory range from F0000h to FFFFFh.

The once0_n pin (ONCE – ON Circuit Emulation) and its companion pin, once1_n, define the microcontroller mode during reset. These two pins are sampled on the rising edge of res_n and if both are asserted low the microcontroller starts in ONCE mode, else it starts normally. In ONCE mode, all pins are tristated and remain so until a subsequent reset. To prevent the microcontroller from entering ONCE mode inadvertently, this pin has a weak pull-up that is only present during reset. This pin is not tristated during bus hold.

2.2.45 uzi_n/clksel2_n/pio26—Upper Zero Indicate (synchronous output)/clock select 2 (input, pullup)

This pin allows the designer to determine if an access to the interrupt vector table is in progress by ORing it with Bits [15–10] of the address and data bus (ad15–ad10 on the IA186ER and ao15–ao10 on the IA188ER). The uzi_n is the logical OR of the inverted a19–a16 bits. It asserts in the first period of a bus cycle and is held throughout the cycle.

clksel2_n is combined with s6/clksel1_n/pio29 to select clock mode. If low, part enters clock mode x1. Default, because of pull-ups, is for x4 clock mode. This is sampled on the rise of reset.

2.2.46 v_{cc}—Power Supply (input)

These pins supply power (+3.3V $\pm$10%) to the microcontroller.

Innovasic®

2.2.47 whb_n (IA186ER)—Write High Byte (synchronous output with tristate)

The whb_n and wlb_n pins indicate to the system which bytes of the data bus (upper, lower, or both) are taking part in a write cycle. The whb_n is asserted with ad15−ad8 and is the logical OR of bhe_n and wr_n. It is tristated during reset.

2.2.48 wlb_n/wb_n—Write Low Byte (IA186ER) (synchronous output with tristate)/Write Byte (IA188ER) (synchronous output with tristate)

The wlb_n and whb_n pins indicate to the system which bytes of the data bus (upper, lower, or both) are taking part in a write cycle. The wlb_n is asserted with ad7−ad0 and is the logical OR of ad0 and wr_n. It is tristated during reset.

On the IA188ER microcontroller, wb_n provides an indication that a write to the bus is occurring. It shares the same early timing as that of the non-multiplexed address bus, and is associated with ad7−ad0. It is tristated during reset.

2.2.49 wr_n—Write Strobe (synchronous output)

The wr_n pin indicates to the system that the data currently on the bus is to be written to a memory or I/O device. It is tristated during a bus hold or reset.

2.2.50 x1—Crystal Input (input)

The x1 and x2 pins are the connections for a fundamental-mode, parallel-resonant crystal used by the internal oscillator circuit. An external clock source for the microcontroller is connected to x1. The x2 pin is left unconnected.

2.2.51 x2—Crystal Input (input)

The x1 and x2 pins are the connections for a fundamental-mode, parallel-resonant crystal used by the internal oscillator circuit. An external clock source for the microcontroller is connected to x1. The x2 pin is left unconnected.

2.3   Pins Used by Emulators

The following pins are used by emulators:

- a19−a0
- ao15−ao8 (on the IA188ER)
- ad7−ad0
- ale
- bhe_n/aden_n (on the IA186ER)
- clkouta
- rfsh2_n/aden_n (on the IA188ER)

Innovasic®

- rd_n
- s2_n–s0_n
- s6/clksel1_n
- uzi_n/clksel2_n

Emulators require that s6/clksel1_n and uzi_n/clksel2_n be configured as their normal functions (i.e., as s6 and uzi_n, respectively). Holding bhe_n/aden_n (IA186ER) or rfsh_n/aden_n (IA188ER) low during the rising edge of res_n, will cause s6 and uzi_n to be configured in their normal functions at reset instead of PIOs.

3. Maximum Ratings, Thermal Characteristics, and DC Parameters

The absolute maximum ratings, thermal characteristics, and DC parameters are provided in Tables 11 through 13, respectively.

Table 11. IA186ER and IA188ER Absolute Maximum Ratings

Parameter	Rating
Storage Temperature	−40°C to +150°C
Voltage on any Pin with Respect to v_{ss}	−0.3V to +(v_{cc} + 0.3) V

Table 12. IA186ER and IA188ER Thermal Characteristics

Symbol	Characteristic	Value
T_A	Ambient Temperature	-40°C to 85°C

Table 13. DC Characteristics Over Industrial Operating Ranges

Symbol	Parameter Description	Test Conditions	Min	Max	Unit
V_{CC}	Supply Voltage (@ 3.3V Operation)	–	3.0	3.6	V
V_{IL}	Input Low Voltage	–	–	0.8	V
V_{IL1}	Clock Input Low Voltage	–	–	0.8	V
V_{IH}	Input High Voltage	–	2.0	v_{cc} +2.2	V
V_{OL}	Output Low Voltages	I_{OL} = 2 - 2.4 mA	–	0.40	V
V_{OH}	Output High Voltages	I_{OH} = −2.4 mA @ 2.4 V	2.4	v_{cc} +0.5	V
I_{CC}	Power Supply Current @ 0°C	v_{cc} = 3.3 V	–	5.9	mA/ MHz
I_{LI}	Input Leakage Current	–	–	±10	µA
I_{LO}	Output Leakage Current	–	–	±10	µA

4.   Device Architecture

A functional block diagram of the IA186ER/IA188ER is shown in Figure 7. This microcontroller consists of the following functional blocks.

- Bus Interface and Control (BIC)
- 32 Kbytes RAM
- Peripheral Control and Registers
- Chip Selects and Control (CSC)
- Programmable I/O
- Clock and Power Management
- DMA
- Interrupt Controller
- Timers
- Asynchronous Serial Port
- Synchronous Serial Interface
- Watchdog Timer
- Instruction Decode and Execution

4.1   Bus Interface and Control

BIC manages all accesses to external memory, external peripherals and the internal 32 Kbyte RAM. These peripherals may be mapped either in memory space or I/O space. The BIC supports both multiplexed and non-multiplexed bus operations. Multiplexed address and data are provided on the ad15–ad0 bus, while a non-multiplexed address is provided on the a19–a0 bus. The *a* bus provides address information for the entire bus cycle (t_1–t_4), while the *ad* bus provides address information only during the first phase of the bus cycle (t_1). For more details regarding bus cycles, see the AC waveforms at the end of this datasheet.

The IA186ER microcontroller provides two signals that serve as byte write enables, write high byte (whb_n) and write low byte (wlb_n). The IA188ER microcontroller requires only a single write byte (wb_n) signal to support its 8-bit data bus. The whb_n is the logical OR of the bhe_n and wr_n. The wlb_n is the logical OR of ad0 and wr_n. The wb_n is low whenever a byte is written to the IA188ER data bus ad7–ad0.

The byte write enables are driven in conjunction with the non-multiplexed address bus a19–a0 to support the timing requirements of common SRAMs.

The BIC also provides support for PSRAM devices. PSRAM is supported in only the lower chip select (lcs_n) area. In order to support PSRAM, the CSC must be appropriately programmed (see Section 4.7, Chip Selects).

4.2 Clock and Power Management

A phase-lock-loop (PLL) and a second programmable system clock output (clkoutb) are included in the clock and power management unit. See Figure 8.
Figure 8. Crystal Configuration

4.3 System Clocks

If required, the internal oscillator can be driven by an external clock source that should be connected to x1, leaving x2 unconnected.

The clock outputs clkouta and clkoutb may be enabled or disabled individually (Power-Save Control register (PDCON) Bits [11−8]). These clock control bits allow one clock output to run at the internal system frequency and the other to run at the power-save frequency (see Figure 9).
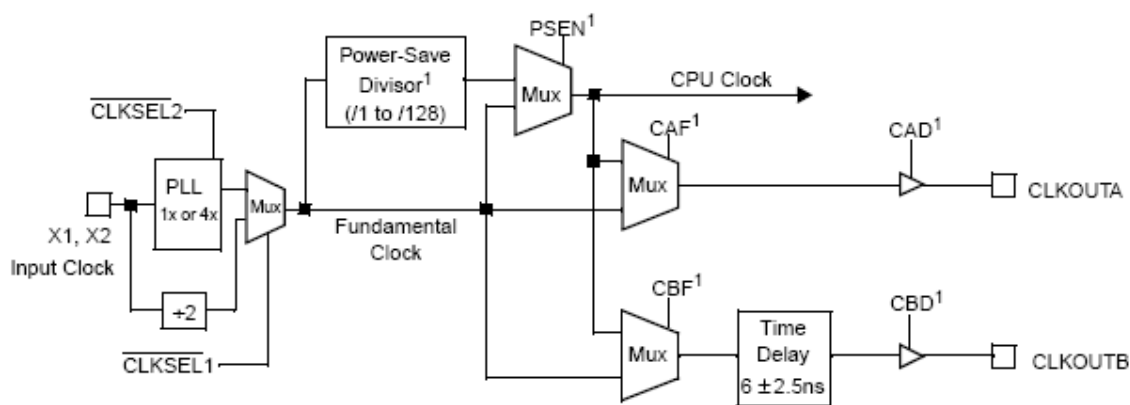

Notes:
1. Set via PDCON Register

Figure 9. Organization of Clock

UNCONTROLLED WHEN PRINTED OR COPIED
Page 46 of 146

http://www.innovasic.com
Customer Support:
1-888-824-4184

4.4 Power-Save Mode

The CPU and peripherals operate at a slower clock frequency when in power save mode, reducing power consumption and thermal dissipation. Should an interrupt occur, the microcontroller returns to its normal operating frequency automatically on the internal clock's next rising edge in t_3. Any clock-dependent devices should be reprogrammed for the change in frequency during the power-save mode period.

4.5 Initialization and Reset

res_n (Reset) must be held low for 1 mS during power-up to initialize the microcontroller correctly. This operation makes the device cease all instruction execution and local bus activity. The microcontroller begins instruction execution at physical address FFFF0h when res_n becomes inactive and after an internal processing interval with ucs_n is asserted and three wait states. Reset also sets up certain registers to predetermined values and resets the Watchdog timer.

4.6 Reset Configuration Register

The data on the address/data bus (ad15–ad0 for the IA186ER, ao15–ao8 and ad7–ad0 for the IA188ER) are written into the Reset Configuration register when reset is low. This data is held in the Reset Configuration register after Reset is de-asserted. This configuration data may be placed on the address/data bus by using weak external pull-up and pull-down resistors or applied to the bus by an external driver, as the processor does not drive the bus during reset. It is a method of supplying the software with some initial data after a reset; for example, option jumper positions.

4.7 Chip Selects

Chip-select generation is programmable for memories and peripherals. Programming is also available to produce ready- and wait-state generation plus latched address bits a1 and a2. For all memory and I/O cycles, the chip-select lines are active within their programmed areas, regardless of whether they are generated by the internal DMA unit or the CPU.

There are six chip-select outputs for memories and a further six for peripherals whether in memory or I/O space. The memory chip-selects are able to address three memory ranges, whereas the peripheral chip-selects are used to address 256-byte blocks that are offset from a programmable base address. Writing to a chip-select register enables the related logic even if the pin in question has another function (e.g., if the pin is programmed to be a PIO). In addition, there is a chip-select for the internal memory.

4.8 Chip - Select Timing

For normal timing, the ucs_n and lcs_n outputs are asserted with the non-multiplexed address bus. The other chip selects assert with the multiplexed address/databus.

Innovasic®

IA211110517-02
UNCONTROLLED WHEN PRINTED OR COPIED
Page 47 of 146

http://www.innovasic.com
Customer Support:
1-888-824-4184

4.9   Ready- and Wait-State Programming

Each of the memory or peripheral chip-select lines can require a ready signal that can be the ardy or srdy signal. The chip-select control registers (UMCS, LMCS, MMCS, PACS, and MPCS) each have a single bit that selects whether the external ready signal is to be used or not (R2, Bit [2]). R1 and R0 (Bits [1–0]) in these registers control the number of wait states that are inserted during each access to a memory or peripheral location (from 0 to 3). The control registers for pcs3_n–pcs0_n use three bits, R3, R1–R0 (Bits [3], [1–0]) to provide 5, 7, 9, and 15 wait-states in addition to the original values of 0 to 3 wait states.

In the case where an external ready has been selected as required, internally programmed wait-states will always be completed before the external ready can finish or extend a bus cycle. As an example, consider a system in which the number of wait states to be inserted has been set to 3. The external ready pin is sampled by the processor during the first wait cycle. The access is completed after 7 cycles (4 cycles plus 3 wait cycles) if the ready is asserted. Alternatively, if the ready is not asserted during the first wait cycle, the access is prolonged until ready is asserted and two more wait states are inserted followed by t_4.

4.10   Chip Select Overlap

Overlapping chip selects are configurations where more than one chip select is asserted for the same physical address. For example, if PCS is configured in I/O space with LCS or any other chip select configured for memory, address 00000h is not overlapping the chip selects.

> *Note: It is not recommended that multiple chip-select signals be asserted for the same physical address, although it may be inescapable in certain systems. If this is the case, then all overlapping chip-selects must have the same external ready configuration and the same number of wait states to be inserted into access cycles.*

Internal signals are employed to access the peripheral control block (PCB) and these signals serve as chip selects that are configured with no wait states and no external ready. Therefore, the PCB can be programmed with addresses that overlap external chip selects only if these chip selects are configured in the same manner.

> *Note: Caution is advised in the use of the DA bit in the LMCS or UMCS registers when overlapping an additional chip select with either the lcs_n or ucs_n. Setting the DA bit to 1 prevents the address from being driven onto the AD bus for all accesses for which the respective chip select is active, including those for which multiple selects are active.*

The mcs_n and pcs_n pins are dual-purpose pins, either as chip selects or PIO inputs or outputs. However, the respective ready- and wait-state configurations for their chip-select function will be in effect regardless of the function for which these pins are programmed. This requires that

even if these pins are configured as PIO and enabled (by writing to the MMCS and MPCS registers for the mcs_n chip selects and to the PACS and MPCS registers for the pcs_n chip selects), the ready- and wait-state settings for them must agree with those for any overlapping chip selects as though they were configured as chip selects.

Although pcs4_n is not available as an external pin, it has ready- and wait-state logic and must follow the rules for overlapping chip-selects. Conversely, pins pcs6_n and pcs5_n have ready- and wait-state logic that is disabled when configured as address bits a2 and a1, respectively.

> *Note: If chip-select configuration rules are not followed, the processor may hang with the appearance of waiting for a ready signal even in a system where ready (ardy or srdy) is always set to 1.*

4.11 Upper Memory Chip Select

The ucs_n chip select is for the top of memory. On reset, the microcontroller begins fetching and executing instructions at memory location FFFF0h. As a result, upper memory is usually used for instruction memory. To this end, ucs_n is active on reset and has a memory range of 64 Kbytes (F0000h to FFFFFh) by default, along with external ready required and 3 wait states automatically inserted. The lower boundary of ucs_n is programmable to provide ranges of 64 to 512 Kbytes.

4.12 Low Memory Chip Select

The lcs_n chip-select is for lower memory. As the interrupt vector table is at the bottom of memory beginning at 00000h, this pin us usually used for control data memory. Unlike ucs_n, this pin is inactive on reset, but can be activated by any read or write to the LMCS register.

4.13 Midrange Memory Chip Selects

There are four midrange chip selects, mcs3_n–mcs0_n, which may be used in a user-located memory block. With some exceptions, the base address of the memory block may be located anywhere in the 1-Mbyte memory address space (those used by the ucs_n and lcs_n chip selects, as well as the pcs6_n, pcs5_n, and pcs3_n–pcs0_n, are excluded). If the pcs_n chip selects are mapped to I/O space, then the MCS address range can overlap the PCS address range.

Both the Midrange Memory Chip Select (MMCS) register and the MCS and PCS auxiliary (MPCS) registers are used to program the four midrange chip selects. The MPCS register is used to configure the block size, whereas the MMCS register configures the base address, the ready condition, and the wait states of the memory block accessed by the mcs_n pin. The chip selects (mcs3_n–mcs0_n) are activated by performing a write operation of the MMCS and MPCS registers. The assertion of the MCS outputs occurs with the same timing as the multiplexed AD address bus (ad15–ad0 on the IA186ER or ao15–ao8 and ad7–ad0 on the IA188ER). The a19–

I Innovasic®

Customer Support:
1-888-824-4184

a0 may be used for address selection, but the timing will be delayed by a half clock cycle over the timing used for the ucs_n and lcs_n.

4.14   Peripheral Chip Selects

There are six peripheral chip selects (pcs6_n, pcs5_n, and pcs3_n–pcs0_n) that may be used within a user-defined memory or I/O block. The base address of this user-defined memory block can be located anywhere within the 1-Mbyte memory address space except for the spaces associated with the ucs_n, lcs_n, and mcs_n chip selects. Or it may be programmed to the 64 Kbyte I/O space. The pcs4_n pin is not available.

Both the Peripheral Chip Select (PACS) register and the MCS and PCS Auxiliary register (MPCS) registers are used to program the six peripheral chip selects pcs6_n, pcs5_n, and pcs3_n–pcs0_n. The PACS register sets the base address, the ready condition, and the wait states for the pcs3_n–pcs0_n outputs.

The MPCS register configures pcs6_n and pcs5_n pins as either chip selects or address pins a1 and a2, respectively. When these pins are chip selects, the MPCS register also configures them as being active during memory or I/O bus cycles and their ready condition and wait states.

None of the pcs_n pins are active at reset. Both the Peripheral Chip Select (PACS) register and the MCS and PCS Auxiliary register (MPCS) registers must be read or written to activate the pcs_n pins as chip selects.

The pcs6_n and pcs5_n may be programmed to have 0 to 3 wait states, whereas pcs3_n–pcs0_n may be programmed to have these and 5, 7, 9, or 15 wait states.

4.15   Refresh Control

The Refresh Control Unit (RCU) generates refresh bus cycles. The RCU generates a memory read request after a programmable period of time to the bus interface unit.

The ENA bit in the Enable RCU register (EDRAM) enables refresh cycles, operating off the processor internal clock. If the processor is in power-save mode, the RCU must be reconfigured for the new clock rate.

If the hlda pin is asserted when a refresh request is initiated (indicating a bus hold condition), the processor disables the hlda pin to allow a refresh cycle to be performed. The external circuit bus master must deassert the *hold* signal for at least one clock period to permit the execution of the refresh cycle.

4.16   Interrupt Control

Interrupt requests originate from a variety of internal and external sources that are arranged by the internal interrupt controller in priority order and presented one by one to the processor.

Six external interrupt sources—five maskable (int4–int0) and one nonmaskable (NMI)—are connected to the processor and six internal interrupt sources (three timers, two DMA channels, and the asynchronous serial port that are not brought out to external pins).

The five external maskable interrupt request pins can be used as direct interrupt requests. However, should more interrupts be needed, int3–int0 may be used with the 82C59A-compatible external interrupt controller. By programming the internal interrupt controller to slave mode, an 82C59A-compatible external interrupt controller can be used as the system master. Interrupt nesting can be used in all cases that permit interrupts of a higher priority to interrupt those of a lower priority.

When an interrupt is accepted, other interrupts are disabled, but may be re-enabled by setting the Interrupt Enable Flag (IF) in the Processor Status Flags register during the Interrupt Service Routine (ISR). Setting IF permits interrupts of equal or greater priority to interrupt the currently running ISR.

Further interrupts from the same source will be blocked until the corresponding bit in the In-Service register (INSERV) is cleared. Special Fully Nested mode (SFNM) is invoked for int0 and int1 by the SFNM bit in the INT0 and INT1 control register, respectively, when this bit is set to 1. In this mode, a new interrupt may be generated by these sources regardless of the in-service bit. The following table shows the priorities of the interrupts at POR.

4.16.1 Interrupt Types

Table 14 presents interrupt names, types, vector table address, End-of-Interrupt (EOI) type, overall priority, and related instructions.

Table 14. Interrupt Types

Interrupt Name	Interrupt Type	Vector Table Address	EOI Type	Overall Priority	Related Instructions
Divide Error Exception[a]	00h	00h	NA	1	DIV, IDIV
Trace Interrupt[b]	01h	04h	NA	1A	All
Non-maskable Interrupt (NMI)	02h	08h	NA	1B	–
Breakpoint Interrupt[a]	03h	0ch	NA	1	INT3
INT0 Detected Overflow Exception[a]	04h	10h	NA	1	INT0
Array Bounds Exception[a]	05h	14h	NA	1	BOUND
Unused Opcode Exception[a]	06h	18h	NA	1	Undefined Opcodes
ESC Opcode Exception[a,c]	07h	1ch	NA	1	ESC Opcodes
Timer 0 Interrupt[d,e]	08h	20h	08h	2A	–
Timer 1 Interrupt[d,e]	12h	48h	08h	2B	–
Timer 2 Interrupt[d,e]	13h	4ch	08h	2C	–

Note: If the priority levels are not changed, the default priority level will be used for the interrupt sources.
[a]Instruction execution generates interrupts.
[b]Performed in the same manner as for the 8086 and 8088.
[c]An ESC opcode causes a trap.
[d]Because only one IRQ is generated for the three timers, they share priority level with respect to other sources. The timers have an interrupt priority order among themselves (2A > 2B > 2C).
[e]These interrupt types are programmable in slave mode.
[f]Not available in slave mode.

4.17   Timer Control

The IA186ER and IA188ER each have three 16-bit programmable timers. Timer 0 and Timer 1 each has an input and output connected to external pins that permits it to count or to time events as well as to produce variable duty-cycle waveforms or non-repetitive waveforms. Timer 1 can also be configured as a Watchdog timer.

Because Timer 2 does not have external connections, it is confined to internal functions such as real-time coding, time-delay applications, a prescaler for Timer 0 and Timer 1, or to synchronize DMA transfers.

The Peripheral Control Block contains eleven 16-bit registers to control the programmable timers. Each timer-count register holds the present value of its associated timer and may be read from or written to whether or not the timer is in operation. The microcontroller increments the value of the timer-count register when a timer event takes place.

The value stored in a timer's associated maximum count register determines its maximum count value. Upon reaching it, the timer count register is reset to 0 in the same clock cycle that this count was attained. The timer count register does not store this maximum value. Both Timer 0 and Timer 1 have a primary and a secondary maximum count register that permits each to alternate between two discrete maximum values.

Timer 0 and Timer 1 may have the maximum count registers configured in either primary only or both primary and secondary. If the primary only is configured to operate, on reaching the

I Innovasic ®

Page 52 of 146

http://www.innovasic.com
Customer Support:
1-888-824-4184

maximum count, the output pin will go low for one clock period. If both the primary and secondary registers are enabled, the output pin reflects the state of the register in control at the time. This generates the required waveform that is dependent on the two values in the maximum count registers.

Because they are polled every fourth clock period, the timers can operate at a quarter of the internal clock frequency. Although an external clock may be used, the timer output may take six clock cycles to respond to the input.

4.18 Direct Memory Access (DMA)

DMA frees the CPU from involvement in transferring data between memory and peripherals over either one or both high-speed DMA channels. Data may be transferred from memory to I/O, I/O to memory, memory to memory, or I/O to I/O. DMA channels can be connected to the asynchronous serial port.

The IA186ER supports the transfer of both bytes and words to and from even or odd addresses. It does not support word transfers to memory that is configured for byte accesses. The IA188ER does not support word transfers at all. Each data transfer will take two bus cycles (a minimum of 8 clock cycles).

There are four sources of DMA requests for both DMA channels:

- The channel request pin (drq1–drq0)
- Timer 2
- The system software
- Asynchronous serial port

Each channel may be programmed to have a different priority either to resolve a simultaneous DMA request or to interrupt a transfer on the other channel.

4.19 DMA Operation

The PCB contains six registers for each DMA channel to control and specify the operation of the channel:

- Two registers to store a 20-bit source address
- Two registers to store a 20-bit destination address
- One 16-bit transfer-count register
- One 16-bit control register

The number of DMA transfers required is designated in the DMA Transfer Count register and may contain up to 64 Kbytes or words. It will end automatically. DMA channel function is

Customer Support:
1-888-824-4184

defined by the control registers. Like the other five registers, these may be changed at any time (including during a DMA transfer) and are implemented immediately.

4.20   DMA Channel Control Registers

See Section 5.1.9, D1CON (0dah) and D0CON (0cah). The DMA channel control registers specify the following:

- Whether the data destination is in memory or I/O space (Bit [15])

- Whether the destination address is incremented, decremented, or unchanged after each transfer (Bits [14–13])

- Whether the data source is in memory or I/O space (Bit [12])

- Whether the source address is incremented, decremented, or unchanged after each transfer (Bits [11–10])

- Whether DMA transfers cease upon reaching a designated count (Bit [9])

- Whether the last transfer generates an interrupt (Bit [8])

- Synchronization mode (Bits [7–6])

- The relative priority of one DMA channel with respect to the other (Bit [5])

- Acceptance of DMA requests from Timer 2 (Bit [4])

- Byte or Word transfers (Bit [0])

4.21   DMA Priority

With the exception of word accesses to odd memory locations or between locked memory addresses, DMA transfers have a higher priority than CPU transfers. Because the CPU cannot access memory during a DMA transfer and a DMA transfer cannot be suspended by an interrupt request, continuous DMA activity will increase interrupt delay. An NMI request halts any DMA activity, however, enabling the CPU to respond promptly to the request.

4.22   Asynchronous Serial Port

The asynchronous serial port employs standard industry communication protocols in its implementation of full duplex, bi-directional data transfers. The port can be either the source or destination of DMA transfers.

IA211110517-02
UNCONTROLLED WHEN PRINTED OR COPIED
Page 54 of 146

http://www.innovasic.com
Customer Support:
1-888-824-4184

The following features are supported:

- Full-duplex data transfers
- 7- or 8-bit data transfers
- Odd, even, or no parity
- One or two stop bits
- Error detection provided by parity, framing, or overrun errors
- DMA to and from the port
- The port has its own maskable interrupt
- The port has an independent baud-rate generator
- Maximum baud rate is 1/32 of the processor clock
- Transmit and receive lines are double-buffered

In power-save mode the baud rate generator divide factor must be re-programmed to compensate for the change in clock rate.

4.23   Synchronous Serial Port

The synchronous serial port allows the microcontrollers to communicate with ASICs that are required to be programmed but have a pin shortage. The four-pin interface allows half-duplex, bi-directional data transfer at a maximum of 25 Mbits/sec.

The synchronous serial interface of the IA186ER/ IA188ER operates as the master port in a master/slave arrangement.

There are four pins in the synchronous serial interface for communication with the system elements. These pins are two enables (SDEN0 and SDEN1), a clock (SCLK), and a data pin (SDATA).

In power-save mode, the baud rate generator divide factor must be re-programmed to compensate for the change in clock rate.

4.24   Programmable I/O (PIO)

Thirty-two pins are programmable as I/O signals (PIO). Table 15 presents them in both numeric and alphabetic order. Because programming a pin as a PIO disables its normal function, it should be done only if the normal function is not required. A PIO pin can be programmed as an input or output with or without a weak pull-up or pull-down. A PIO pin can be also programmed as an open-drain output. Each PIO pin regains default status after a POR.

[a]Input with pullup option available when used as PIO.
[b]Emulators use these pins and also a15–a0, ad15–ad0 (IA186ER), ale, bhe_n (IA186ER), clkouta, nmi, res_n, and s2_n–s0_n.
[c]If bhe_n/aden_n (IA186ER) or rfsh_n/aden_n (IA188ER) is held low during POR, these pins will revert to normal operation.
[d]Input with pulldown option available when used as PIO.

These default status settings may be changed as desired.

After POR, a19–a17, the three most significant bits of the address bus, start with their normal function, allowing the processor to begin fetching instructions from the boot address FFFF0h. Normal function is also the default setting for dt/r_n, den_n, and srdy after POR.

If the ad15–ad0 bus override is enabled, s6/clksel1_n and uzi_n/clksel2_n automatically return to normal operation. The ad15–ad0 bus override is enabled if either the bhe_n/aden_n for the IA186ER or the rfsh2_n/aden_n for the IA188ER is held low during POR.

4.25   Watchdog Timer

The WDT operates in real WDT fashion and may be used to prevent loss of control in the event that software does not respond in an expected manner. The WDT is active after reset, has a maximum timeout count, and is programmed for system reset mode. The WDT control register (WDTCON) may be written to only once after reset. This is accomplished by writing 3333h, then CCCCh followed by the new configuration data to the WDTCON register. Provided they do not include access to the WDTCON register, any number of operations may be performed between these two words, including memory and I/O reads and writes.

Writing AAAAh then 5555h to the WDTCON register resets the current count. This count cannot be read. Provided they do not include access to the WDTCON register, any number of operations may be performed between these two words, including memory and I/O reads and writes. Use of these sequences is intended to prevent executing code from blocking a WDT event. With the WDT, a maximum 1.34-second timeout period is possible in a 50-MHz system.

The WDT can be programmed to generate either an NMI or a system reset when it times out. If programmed to generate an NMI, the NMIFLAG (Bit [12]) in the WDTCON register will be set when it occurs. This flag should be tested by the NMI interrupt service routine (ISR) to establish whether the WDT or an external source generated the interrupt. If set by writing the 3333h and CCCCh sequence followed by the configuration data that includes clearing NMIFLAG, the ISR should clear this flag. If the NMIFLAG is set while a second WDT timeout occurs, a WDT system reset is generated in place of a second NMI interrupt.

The RSTFLAG (Bit [13]) in the WDTCON register is set if a WDT reset is generated, due to one WDT occurrence while the WDT is programmed to generate resets, or because a WDT event occurred with the NMIFLAG set. This permits system initialization code to distinguish between a WDT reset and hardware reset and take appropriate action. The RSTFLAG is cleared by a read or write to the WDTCON register. During a WDT reset, the external pins are not re-sampled, ensuring that clocking, reset configuration register, and any other features that are user programmable during reset do not change when a WDT system reset occurs. All other activities are the same as those of a normal system reset.

4.26   Internal Memory

Integrated 32 Kbyte of internal RAM provides the same performance as zero wait state external memory. This memory is configured with an internal chip select register.

5.   Peripheral Architecture

5.1   Control and Registers

The on-chip peripherals in the IA186ER/IA188ER are controlled from a 256-byte block of internal registers. Although these registers are actually located in the peripherals they control, they are addressed within a single 256-byte block of I/O space and are treated as a functional unit. A list of these registers is presented in Table 16.

Write operations performed on the IA188ER should be 8-bit writes, resulting in 16-bit data transfers to the Peripheral Control Block (PCB) register. Only word reads should be performed to the PCB registers.   If unaligned read and write accesses are performed on either the IA186ER or IA188ER, indeterminate behavior may result.

> *Note: Adhere to these instructions while writing code to avoid errors.*

5.1.1   RELREG (0feh)

The Peripheral Control Block RELocation REGister maps the entire Peripheral Control Block Register Bank to either I/O or memory space. In addition, RELREG contains a bit that places the interrupt controller in either master or slave mode. The RELREG contains 20ffh at reset (see Table 17).

Table 17. Peripheral Control Block Relocation Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	S/Mn	Reserved	IO/Mn	RA19– RA8											

- Bit [15]—Reserved.

- Bit [14]—S/Mn → When set to 1, this bit places the interrupt controller into slave mode. When 0, it is in master mode.

- Bit [13]—Reserved.

- Bit [12]—IO/Mn → When set to 1, the Peripheral Control Block is mapped into memory space. When 0, this bit maps the Peripheral Control Block Register Bank into IO space.

- Bits [11–0]—RA19–RA8 → Sets the base address (upper 12 bits) of the Peripheral Control Block Register Bank. RA7–RA0 default to 0. When Bit [12] (IO/Mn) is set to 1, RA19–RA16 are ignored.

5.1.2   RESCON (0f6h)

The RESet CONfiguration Register latches user-defined information present at specified pins at the rising edge of reset. The contents of this register are read-only and remain valid until the next reset. The RESCON contains user-defined information at reset (see Table 18).

Table 18. Reset Configuration Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RC15–RC0															

- Bits [15–0]—RC15–RC0 → At the rising edge of reset, the values of specified pins (ad15–ad0 for the IA186ER and ao15–ao8 and ad7–ad0 for the IA188ER) are latched into this register.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSEN	Reserved			CBF	CBD	CAF	CAD	Reserved					F2	F1	F0

- Bit [15]—PSEN → When set to 1, enables the power-save mode causing the internal operating clock to be divided by the value in F2–F0. External interrupts or interrupts from internal interrupts automatically clear PSEN. Software interrupts and exception do not clear PSEN.

> *Note: The value of PSEN is not restored upon execution of an IRET instruction.*

- Bits [14–12]—Reserved → These bits read back as 0.

- Bit [11]—CBF → When set to 1, the clkoutb output follows the input crystal (PLL) frequency. When 0, it follows the internal clock frequency after the clock divider.

- Bit [10]—CBD → When set to 1, the clkoutb output is tri-stated. When 0, it is driven as an output per the CBF bit.

- Bit [9]—CAF → When set to 1, the clkouta output follows the input crystal (PLL) frequency. When 0, it follows the internal clock frequency after the clock divider.

- Bit [8]—CAD → When set to 1, the clkouta output is tri-stated. When 0, it is driven as an output per the CAF bit.

- Bits [7–3]—Reserved → These bits read back as 0.

- Bits [2–0]—F2–F0 → These bits control the clock divider as shown below.

> *Note: PSEN must be 1 for the clock divider to function.*

F2	F1	F0	Divider Factor
0	0	0	Divide by 1 (2^0)
0	0	1	Divide by 2 (2^1)
0	1	0	Divide by 4 (2^2)
0	1	1	Divide by 8 (2^3)
1	0	0	Divide by 16 (2^4)
1	0	1	Divide by 32 (2^5)
1	1	0	Divide by 64 (2^6)
1	1	1	Divide by 128 (2^7)

5.1.5   WDTCON (0e6h)

The WatchDog Timer control Register provides control and status for the WDT. The WDTCON contains c080h at reset (see Table 21).

Table 21. Watchdog Timer Control Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ENA	WRST	RSTFLAG	NMIFLAG	TEST	RES			COUNT							

- Bit [15]—ENA → When set to 1, the WDT is enabled. When 0, it is disabled.

- Bit [14]—WRST → When set to 1, an internal WDT reset is generated when the WDT timeout count (COUNT) is reached. When 0, an NMI will be generated once WDT timeout count is reached and the NMIFLAG bit is 0. If the NMIFLAG bit is 1, an internal WDT reset is generated when the WDT timeout count is reached.

- Bit [13]—RSTFLAG → When set to 1, a WDT timeout event has occurred. This bit may be cleared by software or by an external reset.

- Bit [12]—NMIFLAG → When set to 1, a WDT NMI event has occurred. This bit may be cleared by software or by an external reset. If this bit is 1 when WDT timeout occurs, an internal WDT reset is generated regardless of the state of WRST.

1-888-824-4184

- Bit [11]—TEST → This bit is reserved for chip test and should be always set to 0.

- Bits [10–8]—Reserved.

- Bits [7–0]—COUNT → Control the timeout period for the WDT as follows:

$$T_{timeout} = 2^{\,exponent}/frequency \qquad \text{(Equation 1)}$$

Where:

$T_{timeout}$ = The WDT timeout period in seconds.
frequency = The processor frequency in hertz.
exponent = Is based upon count as shown below:

Bit [7]	Bit [6]	Bit [5]	Bit [4]	Bit [3]	Bit [2]	Bit [1]	Bit [0]	Exponent
0	0	0	0	0	0	0	0	NA
X	X	X	X	X	X	X	1	10
X	X	X	X	X	X	1	0	20
X	X	X	X	X	1	0	0	21
X	X	X	X	1	0	0	0	22
X	X	X	1	0	0	0	0	23
X	X	1	0	0	0	0	0	24
X	1	0	0	0	0	0	0	25
1	0	0	0	0	0	0	0	26

5.1.6   EDRAM (0e4h)

The Enable RCU Register provides control and status for the refresh counter. The EDRAM register contains 0000h at reset (see Table 22).

Table 22. Enable Dynamic RAM Refresh Control Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
E	Reserved						T8–T0								

- Bit [15]—E → When set to 1, the refresh counter is enabled and mcs3_n is configured to act as rfsh_n. Clearing E empties the refresh counter and disables refresh requests. The refresh address is unaffected by clearing E.

- Bits [14–9]—Reserved → These bits read back as 0.

- Bits [8–0]—T8–T0 → These bits hold the current value of the refresh counter. They are read-only.

1-888-824-4184

5.1.7   CDRAM (0e2h)

The Clock Prescaler Register determines the period between refresh cycles. The Count for Dynamic RAM (CDRAM) register is undefined at reset (see Table 23).

Table 23. Count for Dynamic RAM Refresh Control Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								RC8–RC0							

- Bits [15–9]—Reserved → These bits read back as 0.

- Bits [8–0]—RC8–RC0 → These bits hold the clock count interval between refresh cycles. In power-save mode, the refresh counter value should be adjusted to account for the clock divider value in PDCON.

> *Note: This value should not be set to less than 18 (12h), else there would never be sufficient bus cycles available for the processor to execute code.*

5.1.8   MDRAM (0e0h)

The Memory Partition Register holds the a19–a13 address bits of the 20-bit base refresh address. The MDRAM register contains 0000h at reset (see Table 24).

Table 24. Memory Partition for Dynamic RAM Refresh Control Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
M6–M0							Reserved								

- Bits [15–9]—M6–M0 → Upper bits corresponding to address bits a19–a13 of the 20-bit memory refresh address. These bits are not available on the a19–a0 bus. When using PSRAM mode, M6–M0 must be programmed to 0000000b.

- Bits [8–0]—Reserved → These bits read back as 0.

5.1.9   D1CON (0dah) and D0CON (0cah)

DMA CONtrol Registers. DMA Control Registers control operation of the two DMA channels. The D0CON and D1CON registers are fff9h at reset (see Table 25).

Table 25. DMA Control Registers

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DM/IOn	DDEC	DINC	SM/IOn	SDEC	SINC	TC	INT	SYN1–SYN0		P	TDRQ	Res	CHG	ST	Bn/W

![Innovasic logo]

- Bit [15]—DM/IOn → Destination Address Space Select selects memory or I/O space for the destination address. When DM/IO is set to 1, the destination address is in memory space. When 0, it is in I/O space.

- Bit [14]—DDEC → Destination Decrement. When set to 1, it automatically decrements the destination address after each transfer. The address is decremented by 1 or 2, depending on the byte/word bit (Bn/W, Bit [0]). The address does not change if the increment and decrement bits are set to the same value (00b or 11b).

- Bit [13]—DINC → Destination Increment. When set to 1, it automatically increments the destination address after each transfer. The address is incremented by 1 or 2, depending on the byte/word bit (Bn/W, Bit [0]). The address does not change if the increment and decrement bits are set to the same value (00b or 11b).

- Bit [12]—SM/IOn → Source Address Space Select selects memory or I/O space for the source address. When set to 1, the source address is in memory space. When 0, it is in I/O space.

- Bit [11]—SDEC → Source Decrement. When set to 1, it automatically decrements the source address after each transfer. The address is decremented by 1 or 2, depending on the byte/word bit (Bn/W, Bit [0]). The address does not change if the increment and decrement bits are set to the same value (00b or 11b).

- Bit [10]—SINC → Source Increment. When set to 1, it automatically increments the source address after each transfer. The address is incremented by 1 or 2, depending on the byte/word bit (Bn/W, Bit [0]). The address does not change if the increment and decrement bits are set to the same value (00b or 11b).

- Bit [9]—TC → Terminal Count. The DMA decrements the transfer count for each DMA transfer. When set to 1, the source or destination synchronized DMA transfers terminate when the count reaches 0. When 0, they do not. Unsynchronized DMA transfers always end when the count reaches 0, regardless of this bit's setting.

- Bit [8]—INT → Interrupt. When this bit is set to 1, the DMA channel generates an interrupt request on completion of the transfer count. However, for an interrupt to be generated, the TC bit must also be set to 1.

- Bits [7–6]—SYN1–SYN0 → Synchronization Type bits select channel synchronization types as shown below. The value of these bits is ignored if TDRQ (Bit [4]) is set to 1. A processor reset causes these bits to be set to 11b.

Synchronization Bit Channel Selection

SYN1	SYN0	Sync Type
0	0	Unsynchronized
0	1	Source Synchronized
1	0	Destination Synchronized
1	1	Reserved

- Bit [5]—P → Relative Priority. When set to 1, selects high priority for this channel relative to the other channel during simultaneous transfers.

- Bit [4]—TDRQ → Timer 2 Synchronization. When set to 1, enables DMA requests from Timer 2. When 0, disables them.

- Bit [3]—Reserved.

- Bit [2]—CHG → Change Start Bit. This bit must be set to 1 to allow modification of the ST bit during a write. During a write, when CHG is set to 0, ST is not changed when writing the control word. The result of reading this bit is always 0.

- Bit [1]—ST → Start/Stop DMA Channel. When set to 1, the DMA channel is started. The CHG bit must be set to 1 for this bit to be modified during the register write. A processor reset causes this bit to be set to 0.

- Bit [0]—Bn/W → Byte/Word Select. When set to 1, word transfers are selected. When 0, byte transfers are selected.

Note: Word transfers are not supported if the chip selects are programmed for 8-bit transfers. The IA188ER does not support word transfers

5.1.10 D1TC (0d8h) and D0TC (0c8h)

DMA Transfer Count Registers. The DMA Transfer Count registers are maintained by each DMA channel. They are decremented after each DMA cycle. The state of the TC bit in the DMA control register has no influence on this activity. If unsynchronized transfers are programmed or if the TC bit in the DMA control word is set, DMA activity ceases when the transfer count register reaches 0. The D0TC and D1TC registers are undefined at reset (see Table 26).

Table 26. DMA Transfer Count Registers

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

- Bits [15–0]—TC15–TC0 → DMA Transfer Count contains the transfer count for the respective DMA channel. Its value is decremented after each transfer.

5.1.11   D1DSTH (0d6h) and D0DSTH (0c6h)

The DMA DeSTination Address High Register. The 20-bit destination address consists of these 4 bits combined with the 16 bits of the respective Destination Address Low Register. A DMA transfer requires that two complete 16-bit registers (high and low registers) be used for both the source and destination addresses of each DMA channel involved. These four registers must be initialized. Each address may be incremented or decremented independently of each other after each transfer. The addresses are incremented or decremented by two for word transfers and incremented or decremented by one for byte transfers. They are undefined at reset (see Table 27).

Table 27. DMA Destination Address High Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												DDA19–DDA16			

- Bits [15–4]—Reserved.

- Bits [3–0]—DDA19–DDA16 → DMA Destination Address High bits are driven onto a19–a16 during the write phase of a DMA transfer.

5.1.12   DIDSTL (0d4h) and D0DSTL (0c4h)

DMA DeSTination Address Low Register. The 16 bits of these registers are combined with the 4 bits of the respective DMA Destination Address High Register to produce a 20-bit destination address. They are undefined at reset (see Table 28).

Table 28. DMA Destination Address Low Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DDA15–DDA0															

- Bits [15–0]—DDA15–DDA0 → DMA Destination Address Low bits are driven onto a15–a0 during the write phase of a DMA transfer.

5.1.13   D1SRCH (0d2h) and D0SRCH (0c2h)

DMA SouRCe Address High Register. The 20-bit source address consists of these 4 bits combined with the 16 bits of the respective Source Address Low Register. A DMA transfer requires that two complete 16-bit registers in the PCB (high and low registers) be used for both the source and destination addresses of each DMA channel involved. Each channel requires that all four address registers be initialized. Each address may be independently incremented or

decremented after each word transfer by 2 or by 1 for byte transfers. They are undefined at reset (see Table 29).

Table 29. DMA Source Address High Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
					Reserved							DSA19–DSA16			

- Bits [15–4]—Reserved.

- Bits [3–0]—DSA19–DSA16 → DMA Source Address High bits are driven onto a19–a16 during the read phase of a DMA transfer.

5.1.14   D1SRCL (0d0h) and D0SRCL (0c0h)

DMA SouRCe Address Low Register. The 16 bits of these registers are combined with the 4 bits of the respective DMA Source Address High register to produce a 20-bit source address. They are undefined at reset (see Table 30).

Table 30. DMA Source Address Low Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
						DSA15–DSA0									

- Bits [15–0]—DSA15–DSA0 → DMA Source Address Low bits are driven onto a15–a0 during the read phase of a DMA transfer.

5.1.15   IMCS (0ach)

Internal memory chip select register. This register controls the generation of chip select for the Internal RAM. This memory can be mapped to any 32K byte boundary. An enable bit is used to activate the memory rather than any write to the register. A separate control bit allows reads from this memory to appear on the external bus. The value of this register is undefined at reset (see Table 31).

Table 31. Internal Memory Chip Select Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BA19 – BA13				SR	RE				Reserved					

- Bits [15 – 11] — Base Address → Upper five bits of 20-bit memory address to which internal memory is mapped. Undefined at reset.

- Bit [10] — SR (Show Read) → When high, drives data on the external AD bus during read of internal memory. Zero at reset.

Innovasic®

IA211110517-02
UNCONTROLLED WHEN PRINTED OR COPIED
Page 68 of 146

http://www.innovasic.com
Customer Support:
1-888-824-4184

- Bits [9] — EN (Internal RAM Enable) → Internal memory is enabled by writing this bit to a 1 and initializing the base address. This bit is a zero at reset.

5.1.16   MPCS (0a8h)

MCS and PCS (MPCS) Auxiliary Register. Because this register controls more than one type of chip select, it is unlike other chip select control registers. The MPCS register contains information for mcs3_n–mcs0_n, pcs6_n–pcs5_n, and pcs3_n–pcs0_n.

The MPCS register also contains a bit that configures the pcs6_n–pcs5_n pins as either chip selects or as alternate sources for the a2 and a1 address bits. Either a2/a1 or pcs6_n–pcs5_n are selected to the exclusion of the other. When programmed for address bits, these outputs can be used to provide latched address bits for a2 and a1.

The pcs6_n–pcs5_n pins are high and not active on processor reset. When the pcs6_n–pcs5_n are configured as address pins, an access to the MPCS register causes them to activate. They do not require corresponding access to the PACS register to be activated. The value of the MPCS register is undefined at reset (see Table 32).

Table 32. MCS and PCS Auxiliary Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	M6–M0							EX	MS	Reserved			R2	R1–R0	

- Bit [15]—Reserved → Set to 1.

- Bits [14–8]—M6–M0 mcs_n Block Size → These seven bits determine the total memory block size for the mcs3_n–mcs0_n chip selects. The size is divided equally among them. The relationship between M6–M0 and the size is shown below.

Select Sizes of M6–M0 by Total Block Size

Total Block Size	Individual Select Size	M6–M0
8K	2K	0000001b
16K	4K	0000010b
32K	8K	0000100b
64K	16K	0001000b
128K	32K	0010000b
256K	64K	0100000b
512K	128K	1000000b

- Bit [7]—EX Pin Selector → This bit determines whether the pcs6_n–pcs5_n pins are configured as chip selects or as alternate outputs for a2 and a1. When set to 2,

they are configured as peripheral chip select pins. When 0, they become address bits a2 and a1, respectively.

- Bit [6]—MS Memory/I/O Space Selector → This bit determines whether the pcs_n pins are active during either memory or I/O bus cycles. When set to 1, the outputs are active for memory bus cycles. When 0, they are active for I/O bus cycles.

- Bits [5–3]—Reserved → Set to 1.

- Bit [2]—R2 Ready Mode → This bit influences only the pcs6_n–pcs5_n chip selects. When set to 1, external ready is ignored. When 0, it is required.

- Bits [1–0]—R1–R0 Wait-State Value → These bits influence only the pcs6_n–pcs5_n chip selects. Their value determines the number of wait states inserted into an access. Up to three wait states can be inserted (R1–R0 = 00b to 11b).

5.1.17 MMCS (0a6h)

Midrange Memory Chip Select (MMCS) Register. Four chip-select pins, mcs3_n–mcs0_n, are provided for use within a user-locatable memory block. Excluding the areas associated with the ucs_n and lcs_n chip selects (and if mapped to memory, the address range of the peripheral chip selects, pcs6_n–pcs5_n and pcs3_n–pcs0_n), the memory block base address can be located anywhere within the 1-Mbyte memory address space. If the pcs_n chip selects are mapped to I/O space, the mcs_n address range can overlap the pcs_n address range.

Two registers program the Midrange Chip Selects. The MMCS register determines the base address, the ready condition, and wait states of the memory block that are accessed through the mcs_n pins. The pcs_n and mcs_n auxiliary (MPCS) register configures the block size. On reset, the mcs3_n–mcs0_n pins are not active. Both the MMCS and MPCS registers must be written to activate these chip selects.

Unlike the ucs_n and lcs_n chip selects, the mcs3_n–mcs0_n outputs assert with the multiplexed *ad* address bus (ad15–ad0 for the IA186ER and ao15–ao8 and ad7–ad0 for the IA188ER), rather than the earlier timing of the a19–a0 bus. If the a19–a0 bus is used for address selection, the timing is delayed for a half cycle later than that for ucs_n and lcs_n. The value is undefined at reset (see Table 33).

Table 33. Midrange Memory Chip Select Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BA19–BA13							Reserved						R2	R1–R0	

- Bits [15–9]—BA19–BA13 Base Address → The value of the this pin determines the base address of the memory block that is addressed by the mcs_n chip select pins. These bits

Innovasic®

IA211110517-02
UNCONTROLLED WHEN PRINTED OR COPIED
Page 70 of 146

http://www.innovasic.com
Customer Support:
1-888-824-4184

correspond to a19–a13 of the 20-bit memory address. The remaining bits a12–a0 of the base address are always 0.

- The base address may be any integer multiple of the size of the memory clock selected in the MPCS register. For example, if the midrange block is 32 Kbytes, the block could be located at 20000h or 28000h but not at 24000h.

- If the lcs_n chip select is inactive, the base address of the midrange chip selects can be set to 00000h, because the lcs_n chip select is defined to be 00000h but is unused. Because the base address must be an integer multiple of the block size, a 512K MMCS block size can only be used with the lcs_n chip select inactive and the base address of the midrange chip selects set to 00000h.

- Bits [8–3]—Reserved → Set to 1.

- Bit [2]—R2 Ready mode → This bit determines the mcs_n chip select ready mode. When set to 1, an external ready is ignored. When 0, it is necessary. In each case, the number of wait states inserted in an access is determined by the value of the R1 and R0 bits.

- Bits [1–0]—R1–R0 → Wait-State Value. The value of these bits determines the number of wait states inserted in an access. Up to three wait states can be inserted (R1–R0 = 00b to 11b).

5.1.18 PACS (0a4h)

PeripherAl Chip Select Register. These Peripheral Chip Selects are asserted over a 256-byte range with the same timing as the *ad* address bus. There are six chip selects, pcs6_n–pcs5_n and pcs3_n–pcs0_n, that are used in either the user-locatable memory or I/O blocks. The pcs4_n chip select is not implemented in the IA186ER or IA188ER. Excluding the areas used by the ucs_n, lcs_n, and mcs_n chip selects, the memory block can be located anywhere within the 1-Mbyte address space. These chip selects may also be configured to access the 64-Kbyte I/O space.

Programming the Peripheral Chip Selects uses the Peripheral Chip Select (PACS) and the pcs_n and mcs_n Auxiliary (MPCS) registers. The PACS register establishes the base address, configures the ready mode, and determines the number of wait states for the pcs3_n–pcs0_n outputs.

The MPCS register configures the pcs6_n–pcs5_n pins to be either chip selects or address pins a1 and a2. When these pins are configured as chip selects, the MPCS register determines the ready and wait states for these output pins and whether they are active during memory or I/O bus cycles. These pins are activated as chip selects by writing to the two registers (PACS and MPCS). They are not active on reset. To configure and activate them as address pins, it is

![Innovasic logo] **Innovasic**®

1-888-824-4184

necessary to write to both the PACS and MPCS registers. Pins pcs6_n–pcs5_n can be
configured for 0 to 3 wait states and pcs3_n–pcs0_n can be programmed for 0 to 15 wait states.
The value of the PACS register is undefined at reset (see Table 34).

Table 34. Peripheral Chip Select Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BA19–BA11									Reserved			R3	R2	R1–R0	

- Bits [15–7]—BA19–BA11 → Base Address bits correspond to Bits [19–11] of the 20-bit
  programmable base address of the peripheral chip select block and determine the base
  address. Because I/O addresses are only 16 bits wide, if the pcs_n chip selects are
  mapped to I/O space, Bits BA19-16 must be set to 0000b. The pcs address ranges are
  shown below.

Address Ranges of pcs Chip Selects

pcs_n Line	Range	
	Low	High
pcs0_n	Base Address	Base Address + 255
pcs1_n	Base Address + 256	Base Address + 511
pcs2_n	Base Address + 512	Base Address + 767
pcs3_n	Base Address + 768	Base Address + 1023
Reserved	NA	NA
pcs5_n	Base Address + 1280	Base Address + 1535
pcs6_n	Base Address + 1536	Base Address + 1791

- Bits [6–4]—Reserved → Set to 1.

- Bit [3]—R3 → Wait State Value. See pcs3_n–pcs0_n Wait-State Encoding shown below.

pcs3_n–pcs0_n Wait-State Encoding

R3	R1	R0	Wait States
0	0	0	0
0	0	1	1
0	1	0	2
0	1	1	3
1	0	0	5
1	0	1	7
1	1	0	9
1	1	1	15

- Bit [2]—R2 → Ready Mode. When set to 1, external ready is ignored. When 0, it is
  required. In each case the number of wait states is determined according to the
  pcs3_n–pcs0_n Wait-State Encoding shown above.

Innovasic®

- Bits [1–0]—R1–R0 → Wait-State Value (see pcs3_n–pcs0_n Wait-State Encoding above).

The pcs6_n–pcs5_n and pcs3_n–pcs0_n pins are multiplexed with the PIO pins. For these to function as chip selects, the PIO mode and direction settings for these pins must be set to 0 for normal operation.

5.1.19   LMCS (0a2h)

The Low-Memory Chip Select (LMCS) Register configures the LMCS provided to facilitate access to the interrupt vector table located at 00000h or the bottom of memory. The lcs_n pin is not enabled at reset.

The LCS_n pin is enabled by any write to the LMCS register. The value of the LMCS register is undefined at reset except DA, which is set to 0 (see Table 35).

Table 35. Low-Memory Chip Select Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res	UB2–UB0			Reserved				DA	PSE	Reserved			R2	R1–R0	

- Bit [15]—Reserved → Set to 0.

- Bits [14–12]—UB2–UB0 → Upper Boundary. These bits define the upper boundary of memory accessed by the lcs_n chip select. The list below presents the possible block-size configurations (a 512-Kbyte maximum).

  LMCS Block-Size Programming Values

Memory Block Size	Ending Address	UB2–UB0
64K	0FFFFh	000b
128K	1FFFFh	001b
256K	3FFFFh	011b
512K	7FFFFh	111b

- Bits [11–8]—Reserved → Set to 1.

- Bit [7]—DA → Disable Address. When set to 1, the multiplexed address bus is disabled, providing reduced power consumption. When 0, the address is driven onto the address bus ad15–ad0 during the address phase of a bus cycle. This bit is set to 0 at reset.

  – If bhe_n/aden_n (IA186ER) is held at 0 during the rising edge of res_n, the address bus is always driven, regardless of the setting of DA.

1-888-824-4184

- Bit [6]—PSE → PSRAM Mode Enable. When set to 1, PSRAM support for the lcs_n chip select memory space is enabled. The EDRAM, MDRAM, and CDRAM RCU registers must be configured for auto refresh before PSRAM support is enabled. Setting the enable bit (EN) in the enable RCU register (EDRAM, offset e4h) configures the mcs3_n/rfsh_n as rfsh_n.

- Bits [5–3]—Reserved → Set to 1.

- Bit [2]—R2 → Ready Mode. When set to 1, the external ready is ignored. When 0, it is required. The value of R1–R0 bits determines the number of wait states inserted.

- Bits [1–0]—R1–R0 → Wait-State Value. The value of these bits determines the number of wait states inserted into an access to the lcs_n memory area. This number ranges from 0 to 3 (R1–R0 = 00b to 11b).

5.1.20 UMCS (0a0h)

The Upper Memory Chip Select Register configures the UMCS pin, used for the top of memory. On reset, the first fetch takes place at memory location FFFF0h and thus this area of memory is usually used for instruction memory. The ucs_n defaults to an active state at reset with a memory range of 64 Kbytes (F0000h to FFFFFh), external ready required, and three wait states automatically inserted. The upper end of the memory range always ends at FFFFFh. The lower end of this upper memory range is programmable. The value of the UMCS register is F03Bh at reset (see Table 36).

Table 36. Upper-Memory Chip Select Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	LB2–LB0			Reserved				DA	0	Reserved			R2	R1–R0	

- Bit [15]—Reserved → Set to 1.

- Bits [14–12]—LB2–LB0 Lower Boundary → These bits determine the bottom of the memory accessed by the ucs_n chip select. The UMCS Block-Size Programming Values shown below list the possible block-size configurations (a 512-Kbyte maximum).

UMCS Block-Size Programming Values

Memory Block Size	Starting Address	LB2–LB0	Comments
64K	F0000h	111b	Default
128K	E0000h	110b	–
256K	C0000h	100b	–
512K	80000h	000b	–

- Bits [11–8]—Reserved.

1-888-824-4184

- Bit [7]—DA → Disable Address. When set to 1, the multiplexed address bus is disabled and the address is not driven on the address bus when ucs_n is asserted, providing reduced power consumption. When 0, the address is driven onto the address bus (ad15–ad0) during the address phase of a bus cycle when ucs_n is asserted. This bit is set to 0 at reset.

    - If bhe_n/aden_n (IA186ER) is held at 0 during the rising edge of res_n, the address bus is always driven, regardless of the setting.

- Bit [6]—Reserved → Set to 0.

- Bits [5–3]—Reserved → Set to 1.

- Bit [2]—R2 Ready Mode → When set to 1, the external ready is ignored. When 0, it is required. The value of the R1–R0 bits determines the number of wait states inserted.

- Bits [1–0]—R1–R0 Wait-State Value → The value of these bits determines the number of wait states inserted into an access to the lcs_n memory area. This number ranges from 0 to 3 (R1–R0 = 00b to 11b).

5.1.21 SPBAUD (088h)

Serial Port BAUD Rate Divisor Register. The value in this register determines the number of internal processor cycles in one phase (half-period) of the 32 x serial clock. The contents of these registers must be adjusted to reflect the new processor clock frequency if power-save mode is in effect. The baud rate divisor may be calculated from:

$$\text{BAUDDIV} = (\text{Processor Frequency}/(32 \text{ x baud rate})) -1 \qquad \text{(Equation 2)}$$

By setting the BAUDDIV to 0000h, the maximum baud rate of 1/32 of the internal processor frequency clock is set. Setting BAUDDIV to 129 (81h) provides a baud rate of 9600 at 40 MHz. The baud rate tolerance is +4.6% to −1.9% with respect to the actual serial port baud rate, not the target baud rate (see Table 37).

Table 37. Baud Rates

Baud Rate	Divisor Based on CPU Clock Rate			
	20 MHz	25 MHz	33 MHz	40 MHz
300	4166	5208	6875	8333
600	2083	2604	3437	4166
1200	1041	1302	1718	2083
2400	520	651	859	1041
4800	260	325	429	520
9600	130	162	214	260
14400	42	53	71	85

625 Kbaud	0	NA	NA	1
781.25 Kbaud	NA	0	NA	NA
1.041 Mbaud	NA	NA	0	NA
1.25 Mbaud	NA	NA	NA	0

The value of the SPBAUD register at reset is undefined (see Table 38).

Table 38. Serial Port Baud Rate Divisor Registers

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
							BAUDDIV								

- Bits [15–0]—BAUDDIV Baud Rate Divisor → Defines the divisor for the internal processor clock.

5.1.22 SPRD (086h)

Serial Port Receive Data Register. Data received over the serial port are stored in this register until read. The data are received initially by the receive shift register (no software access) permitting data to be received while the previous data are being read.

The RDR bit (Receive Data Ready) in the serial port status register indicates the status of the SPRD register. A 1 indicates there is valid data in the receive register. The value of the SPRD register is undefined at reset (see Table 39).

Table 39. Serial Port Receive Data Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
			Reserved								RDATA				

- Bits [15–8]—Reserved.

- Bits [7–0]—RDATA → Holds valid data if the RDR bit of the status register is set.

5.1.23 SPTD (084h)

Serial Port Transmit Data Register. Data is written to this register by software, with the values to be transmitted by the serial port. Double buffering of the transmitter allows for the transmission of data from the transmit shift register (no software access) while the next data are written into the transmit register.

The THRE bit in the Serial Port Status register indicates whether there is valid data in the SPTDregister. The THRE bit must be a 1 before writing data to this register to prevent overwriting valid data that is already in the SPTD register. The value of the SPTD register is undefined at reset (see Table 40).

Reserved								TDATA							

- Bits [15–8]—Reserved.

- Bits [7–0]—TDATA → Holds the data to be transmitted.

5.1.24   SPSTS (082h)

Serial Port STatuS Register. This register stores information concerning the current status of the port. The status bits are described below.

The value of the SPSTS register is undefined at reset (see Table 41).

Table 41. Serial Port Status Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									TEMT	THRE	RDR	BRKI	FER	PER	OER

- Bits [15–7]—Reserved → Set to 0.

- Bit [6]—TEMT Transmitter Empty → When both the transmit shift register and the transmit register are empty, this bit is set indicating to software that it is safe to disable the transmitter. This bit is read-only.

- Bit [5]—THRE Transmit Holding Register Empty → When this bit is 1, the corresponding transmit holding register is ready to accept data. This is a read-only bit.

- Bit [4]—RDR Receive Data Ready → When this bit is 1, the SPRD register contains valid data. This is a read_only bit and can be reset only by reading the receive register.

- Bit [3]—BRKI Break Interrupt → This bit indicates that a break has been received when this bit is set to 1 and causes a serial port interrupt request, if RSIE is set.

  Note: This bit should be reset by software.

- Bit [2]—FER Framing Error Detected → When the receiver samples the rxd/pio28 line as low when a stop bit is expected (line high), a framing error is generated setting this bit.

  Note: This bit should be reset by software.

- Bit [1]—PER Parity Error Detected → When a parity error is detected in either mode 1 or 3, this bit is set.

> *Note: This bit should be reset by software.*

- Bit [0]—OER Overrun Error Detected → When new data overwrites valid data in the receive register (because it has not been read) an overrun error is detected setting this bit.

> *Note: This bit should be reset by software.*

5.1.25   SPCT (080h)

Serial Port ConTrol Register. This register controls both transmit and receive parts of the serial port. The value of the SPCT register is 0000h at reset (see Table 42).

Table 42. Serial Port Control Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DMA			Reserved	TXIE	RXIE	LOOP	BRK	BRKVAL	PMODE		WLGN	STP	TMODE	RSIE	RMODE

- Bits [15 - 13]— DMA Control Field → Enables DMA transfers to and from serial port as follows:

DMA Bits	Receive	Transmit
000	No DMA	No DMA
001	DMA0	DMA1
010	DMA1	DMA0
011	RESERVED	
100	DMA0	No DMA
101	DMA1	No DMA
110	No DMA	DMA0
111	No DMA	DMA1

DMA transfers to the serial port act as destination-synchronized transfers. DMA request occurs when THRE is set to 1. Interrupts are disabled regardless of the state of TXIE when DMA transfers are enabled.

DMA transfers from the serial port act as source-synchronized transfers. DMA request occurs when RDR is set to 1. Interrupts are disabled regardless of the state of RXIE when DMA transfers are enabled.

- Bit [12]—Reserved → Set to 0.

- Bit [11]—TXIE Transmitter Ready Interrupt Enable → This bit enables the generation of an interrupt request whenever the transmit holding register is empty (THRE Bit [1]). The

1-888-824-4184

respective port does not generate interrupts when this bit is 0. Interrupts continue to be generated as long as THRE and the TXIE are 1.

- Bit [10]—RXIE Receive Data Ready Interrupt Enable → This bit enables the generation of an interrupt request whenever the receive register contains valid data (RDR Bit [1]). The respective port does not generate interrupts when this bit is 0. Interrupts continue to be generated as long as RDR and the RXIE are 1.

- Bit [9]—LOOP Loop Back → The serial port is placed into the loop-back mode when this bit is set.

- Bit [8]—BRK Send Break → When this bit is set to 1, the txd/pio27 pin is driven to the value in BRKVAL, overriding any data that may be in the course of being shifted out of the transmit shift register.

- Bit [7]—BRKVAL Break Value → This is the value transmitted when BRK is asserted.

- Bits [6–5]—PMODE Parity Mode →See table below. These bits define parity checking and generation 00 at reset.

Parity	Pmode
None	0x
Odd	10
Even	11

- Bit [4]—WLGN Word Length → The number of bits transmitted or received in a frame is determined by the value of this bit. When this bit is 1, the number of data bits in a frame is 8. When 0, it is 7. This bit is 0 at reset.

- Bit [3]—STP Stop Bits → This bit specifies the number of stop bits used to indicate the end of a frame. When this bit is 1, the number of stop bits is 2. When 0, it is 1. This bit is 0 at reset.

- Bit [2]—TMODE Transmit Mode → When this bit is 1, the transmit section of the serial port is enabled. When 0, it is disabled.

- Bit [1]—RSIE Receive Status Interrupt Enable → When an exception occurs during data reception, an interrupt request is generated if enabled by this bit (RSIE = 1). Interrupt requests are made for the error conditions listed in the serial port status register (BRK, OER, PER, and FER). This bit is 0 at reset.

- Bit [0]—RMODE Receive Mode → When this bit is 1, the receive section of the serial port is enabled. When 0, it is disabled. This bit is 0 at reset.

5.1.26 PDATA1 (07ah) and PDATA0 (074h)

PIO DATA Registers. When a PIO pin is configured as an output, the value in the corresponding PIO data register bit is driven onto the pin. However, if the PIO pin is configured as an input, the value on the pin is put into the corresponding bit of the PIO data register. Table 43 lists the default states for the PIO pins.

Table 43. PIO Pin Assignments

PIO Number	Associated Pin Name	Power-On Reset Status
0	tmrin1	Input with pull-up
1	tmrout1	Input with pull-down
2	pcs6/a2	Input with pull-up
3	pcs5/a1	Input with pull-up
4	dt/r_n	Normal operation[a]
5	den_n	Normal operation[a]
6	srdy	Normal operation[b]
7[c]	a17	Normal operation[a]
8[c]	a18	Normal operation[a]
9[c]	a19	Normal operation[a]
10	tmrout0	Input with pull-down
11	tmrin0	Input with pull-up

Table 43. PIO Pin Assignments *(Continued)*

PIO Number	Associated Pin Name	Power-On Reset Status
24	mcs2_n	Input with pull-up
25	mcs3_n/rfsh_n	Input with pull-up
26[c,d]	uzi/clksel2_n	Input with pull-up
27	txd/pio27	Input with pull-up
28	rxd/pio28	Input with pull-up
29[c,d]	s6/clksel1_n	Input with pull-up
30	int4	Input with pull-up
31	int2	Input with pull-up

[a]When used as a PIO pin, it is an input with a pull-up option available.
[b]When used as a PIO pin, it is an input with a pull-down option available.
[c]Emulators use these pins and also a15–a0, ad15–ad0 (IA186ER), ale, bhe_n (IA186ER), clkouta, nmi, res_n, and s2_n–s0_n.
[d]If bhe_n/aden_n (IA186ER) or rfsh2_n/aden (IA188ER) is held low during POR, these pins revert to normal operation.

The value of the PDATA registers is undefined at reset (see Tables 44 and 45).

Table 44. PDATA 0

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PDATA15–PDATA0															

Table 45. PDATA 1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PDATA31–PDATA16															

- Bits [15–0]—PDATA15–PDATA0 PIO Data 0 Bits → This register contains the values of the bits that are either driven on, or received from, the corresponding PIO pins. Depending on its configuration, each pin is either an output or an input. The values of these bits correspond to those in the PIO Direction registers and PIO Mode registers.

- Bits [15–0]—PDATA31–PDATA16 PIO Data 1 Bits → This register contains the values of the bits that are either driven on, or received from, the corresponding PIO pins. Depending on its configuration, each pin is either an output or an input. The values of these bits correspond to those in the PIO direction registers and PIO Mode registers

- The PIO pins may be operated as open-drain outputs by:
  - Maintaining the data constant in the appropriate bit of the PIO data register.
  - Writing the value of the data bit into the respective bit position of the PIO Direction register, so that the output is either 0 or disabled depending on the value of the data bit.

5.1.27   PDIR1 (078h) and PDIR0 (072h)

PIO DIRection Registers. Each PIO pin is configured as an input or an output by the corresponding bit in the PIO Direction register (see Table 46).

Table 46. PIO Mode and PIO Direction Settings

PIO Mode	PIO Direction	Pin function
0	0	Normal operation
0	1	PIO input with pullup/pulldown
1	0	PIO output
1	1	PIO input without pullup/pulldown

The value of the PDIR0 register is FC0Fh at reset (see Table 47).

Table 47. PDIR0

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
							PDIR15–PDIR0								

The value of the PDIR1 register is FFFFh at reset (see Table 48).

Table 48. PDIR1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
							PDIR31–PDIR16								

- Bits [15–0]—PDIR15–PDIR0 PIO Direction 0 Bits → For each bit, if the value is 1, the pin is configured as an input. If 0, as an output. The values of these bits correspond to those in the PIO data registers and PIO mode registers.

- Bits [15–0]—PDIR31–PDIR16 PIO Direction 1 Bits → For each bit, if the value is 1, the pin is configured as an input. If 0, as an output. The values of these bits correspond to those in the PIO Data registers and PIO Mode registers.

5.1.28   PIOMODE1 (076h) and PIOMODE0 (070h)

PIO MODE Registers. Each PIO pin is configured as a PIO or its normal function by the corresponding bit in the PIO mode register. The bit number of PMODE corresponds to the PIO number (see Table 44, PIO Mode and PIO Direction Settings). The value of the PIOMODE0 register is 0000h at reset (see Table 49).

Table 49. PIOMODE0

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Customer Support:
1-888-824-4184

The value of the PIOMODE1 register is 0000h at reset (see Table 50).

Table 50. PMODE1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PMODE31–PMODE16															

- Bits [15–0]—PMODE15–PMODE0 PIO Mode 0 Bits → See Table 46. The values of these bits correspond to those in the PIO data registers and PIO Mode registers.

- Bits [15–0]—PMODE31–PMODE16 PIO Mode 1 Bits → See Table 46. The values of these bits correspond to those in the PIO data registers and PIO Mode registers.

5.1.29   T1CON (05eh) and T0CON (056h)

Timer 0 and Timer 1 Mode and CONtrol Registers. These registers control the operation of Timer 0 and Timer 1, respectively. The value of the T0CON and T1CON registers is 0000h at reset (see Table 51).

Table 51. Timer 0 and Timer 1 Mode and Control Registers

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EN	INHn	INT	RIU	Reserved						MC	RTG	P	EXT	ALT	CONT

- Bit [15]—EN Enable Bit → The timer is enabled when the EN bit is 1. The timer count is inhibited when the EN bit is 0. This bit can only be written if the INHn bit (Bit [14]) is set to 1 in the same operation.

- Bit [14]—INHn Inhibit Bit → Gates the setting of the enable (EN) bit. This bit must be set to 1 in the same write operation that changes the enable (EN) bit. Otherwise, the EN bit will not be changed. This bit always reads 0.

- Bit [13]—INT Interrupt Bit → If set to 1, an interrupt request is generated when the Count register reaches its maximum, MC = 1. In dual maxcount mode, an interrupt request is generated when the count register reaches the value in Maxcount A or Maxcount B. No interrupt requests are generated if this bit is set to 0. If an interrupt request is generated, and the enable bit is then cleared before the interrupt is serviced, the interrupt request will remain.

- Bit [12]—RIU Register in Use Bit → This bit is set to 1 when the Maxcount Register B is used to compare to the timer-count value. It is 0 when the Maxcount Compare A register is used.

- Bits [11–6]—Reserved → Set to 0.

- Bit [5]—MC Maximum Count → When the timer reaches its maximum count, this bit is set to 1 regardless of the interrupt enable bit. This bit is also set every time Maxcount Compare Register A or B is reached when in dual maxcount mode. If preferred, this bit may be used by software polling rather than by interrupts to monitor timer status.

- Bit [4]—RTG Retrigger Bit → This pin controls the timer function of the timer input pin. When set to 1, the count is reset by a 0 to 1 transition on timrin0 or tmrin1. When 0, a high input on tmrin0 or tmrin1 enables the count and a 0 holds the timer value. This bit is ignored if the external clocking (EXT = 1) bit is set.

- Bit [3]—P Prescaler Bit → P is ignored if external clocking is enabled (EXT = 1). Timer 2 prescales the timer when P is set to 1. Otherwise, the timer is incremented on every fourth clkout cycle.

- Bit [2]—EXT External Clock Bit → This bit determines whether an external or internal clock is used. If EXT is 1, an external clock is used. If 0, an internal is used.

- Bit [1]—ALT Alternate Compare Bit → If set to 1, the timer will count to Maxcount Compare A, reset the count register to 0, count to Maxcount Compare B, reset the count register to 0, and begin again at Maxcount Compare A. If 0, it will count to Maxcount Compare A, reset the count register to 0, and begin again at Maxcount Compare A. Maxcount Compare B is not used in this case.

- Bit [0]—CONT Continuous Mode Bit → When set to 1, the timer runs continuously. When 0, the timer stops after each count run and EN will be cleared. If CONT = 0 and ALT = 1, the respective timer counts to the Maxcount Compare A value and resets, then commences counting to Maxcount Compare B value, resets, and stops counting.

5.1.30 T2CON (066h)

Timer 2 Mode and CONtrol Register. This register controls the operation of Timer 2. The value of the T2CON register is 0000h at reset (see Table 52).

Table 52. Timer 2 Mode and Control Registers

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EN	INHn	INT	Reserved							MC	Reserved				CONT

- Bit [15]—EN Enable Bit → The timer is enabled when the EN bit is 1. The timer count is inhibited when the EN bit is 0. Modifying this bit by writing to the T2CON register requires that the INH bit be set to 1 during the same write.

- Bit [14]—INHn Inhibit Bit → Gates the setting of the enable (EN) bit. This bit must be set to 1 in the same write operation that sets the enable (EN) bit. This bit always reads 0.

1-888-824-4184

- Bit [13]—INT Interrupt Bit → An interrupt request is generated, by setting the INT bit to 1, when the Count register reaches its maximum, MC = 1.

- Bits [12–6]—Reserved → Set to 0.

- Bit [5]—MC Maximum Count → When the timer reaches its maximum count, this bit is set to 1, regardless of the interrupt enable bit. If preferred, this bit may be used by software polling rather than by interrupts to monitor timer status.

- Bits [4–1]—Reserved → Set to 0.

- Bit [0]—CONT Continuous Mode Bit → The timer will run continuously when this bit is set to 1. The timer will stop after each count run and EN will be cleared if this bit is set to 0.

5.1.31 T2COMPA (062h), T1COMPB (05ch), T1COMPA (05ah), T0COMPB (054h), and T0COMPA (052h)

Timer Maxcount COMpare Registers. These registers contain the maximum count value that is compared to the respective count register. Timer 0 and Timer 1 each have two compare registers.

If Timer 0 and/or Timer 1 is/are configured to count and compare first to Register A and then Register B, the tmrout0 or tmrout1 signals can be used to generate various duty-cycle wave forms.

Timer 2 has only one compare register, T2COMPA.

If one of these timer maxcount compare registers is set to 0000h, the respective timer will count from 0000h to FFFFh before generating an interrupt request. For example, a timer configured in this manner with a 40-MHz clock will interrupt every 6.5536 mS.

The value of these registers is undefined at reset (see Table 53).

Table 53. Timer Maxcount Compare Registers

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TC15–TC0															

- Bits [15–0]—TC15–TC0 Timer Compare Value → The timer will count to the value in the respective register before resetting the count value to 0.

5.1.32   T2CNT (060h), T1CNT (058h), and T0CNT (050h)

These registers are incremented by one every four internal clock cycles if the relevant timer is enabled.

The Increment of Timer 0 and Timer 1 may also be controlled by external signals tmrin0 and tmrin1 respectively, or prescaled by Timer 2.

Comparisons are made between the count registers and maxcount registers and action taken dependent on achieving the maximum count.

The value of these registers is undefined at reset (see Table 54).

Table 54. Timer Count Registers

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
							TC15–TC0								

- Bits [15–0]—TC15–TC0 Timer Count Value → This register has the value of the current count of the related timer that is incremented every fourth processor clock in internal clocked mode. Alternatively, the register is incremented each time the Timer 2 maxcount is reached if using Timer 2 as a prescaler. Timer 0 and Timer 1 may be externally clocked by tmrin0 and tmrin1 signals.

5.1.33   SPICON (044h) (Master Mode)

Serial Port Interrupt Control Register. This register controls the operation of the asynchronous serial port interrupt source (SPI, Bit [10] in the Interrupt Request register). The value of this register is 001Fh at reset (see Table 55).

Table 55. Serial Port Interrupt Control Registers

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
				Reserved							Reserved	MSK	PR2–PR0		

- Bits [15–5]—Reserved → Set to 0.

- Bit [4]—Reserved → Set to 1.

- Bit [3]—MSK Mask → This bit, when 0, enables the serial port to cause an interrupt. When this bit is 1, the serial port is prevented from generating an interrupt.

- Bits [2–0]—PR2–PR0 Priority → These bits define the priority of the serial port interrupt in relation to other interrupt signals. The interrupt priority is the lowest at 7 at reset. The values of PR2–PR0 are shown below.

Innovasic®

(Low) 7	111b

5.1.34 WDCON (042h) (Master Mode)

WatchDog Timer Interrupt Control Register. These registers control the operation of the Watchdog Timer interrupt source. The value of this register is 000Fh at reset (see Table 56).

Table 56. Watchdog Timer Interrupt Control Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											Reserved	MSK	PR2–PR0		

- Bits [15–5]—Reserved → Set to 0.

- Bit [4]—Reserved → Set to 0.

- Bit [3]—MSK Mask → This bit, when 0, enables the Watchdog Timer to cause an interrupt. When this bit is 1 prevents the Watchdog Timer from generating an interrupt.

- Bits [2–0]—PR2–PR0 Priority → These bits define the priority of the Watchdog Timer interrupt in relation to other interrupt signals. The interrupt priority is the lowest at 7 at reset. The values of PR2–PR0 are shown in the above table.

5.1.35 I4CON (040h) (Master Mode)

This register controls the operation of the int4 signal, which is only intended for use in fully nested mode. The interrupt is assigned to type 10h. The value of the I4CON register is 000Fh at reset (see Table 57).

Table 57. INT4 Control Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

1-888-824-4184

- Bits [15–5]—Reserved → Set to 0.

- Bit [4]—LTM Level-Triggered Mode → The int4 interrupt may be edge- or level-triggered, depending on the value of the bit. If LTM is 1, int4 is active high level-sensitive interrupt. If 0, it is a rising-edge triggered interrupt. The interrupt int4 must remain active (high) until serviced.

- Bit [3]—MSK Mask → The int4 signal can cause an interrupt if the MSK bit is 0. The int4 signal cannot cause an interrupt if the MSK bit is 1.

- Bits [2–0]—PR2–PR0 Priority → These bits define the priority of the interrupt in relation to other interrupt signals. The interrupt priority is the lowest at 7 upon reset. The values of PR2–PR0 are shown in the above table.

5.1.36 I3CON (03eh) and I2CON (03ch) (Master Mode)

INT2/INT3 CONtrol Register. The int2 and int3 are designated as interrupt type 0eh and 0fh, respectively, and may be configured as the interrupt acknowledge pins inta0_n and inta1_n in cascade mode. The value of these registers is 000Fh at reset (see Table 58).

Table 58. INT2/INT3 Control Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											LTM	MSK	PR2–PR0		

- Bits [15–5]—Reserved → Set to 0.

- Bit [4]—LTM Level-Triggered Mode → The int2 or int3 interrupt may be edge- or level-triggered depending on the value of this bit. If LTM is 1, int2 or int3 is an active high level-sensitive interrupt. If 0, int2 or int3 is a rising-edge-triggered interrupt. The interrupt int2 or int3 must remain active (high) until acknowledged.

- Bit [3]—MSK Mask → The int2 or int3 signal can cause an interrupt if the MSK bit is 0. The int2 or int3 signal cannot cause an interrupt if the MSK bit is 1. The Interrupt Mask Register has a duplicate of this bit.

- Bits [2–0]—PR2–PR0 Priority → These bits define the priority of the interrupt int2 or int3 in relation to other interrupt signals. The interrupt priority is the lowest at 7 at reset. The values of PR2–PR0 are shown above.

5.1.37 I1CON (03ah) and I0CON (038h) (Master Mode)

INT0/INT1 CONtrol Register. The int0 and int1 are designated as interrupt type 0ch and 0dh, respectively, and may be configured to use the interrupt acknowledge pins inta0 and inta1 in cascade mode. The value of these registers is 000Fh at reset (see Table 59).

Table 59. INT0/INT1 Control Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
\<td colspan=9 align=center>Reserved									SFNM	C	LTM	MSK	\<td colspan=3 align=center>PR2–PR0		

- Bits [15–7]—Reserved → Set to 0.

- Bit [6]—SFNM Special Fully Nested Mode → This bit enables fully nested mode for int0 or int1 when set to 1.

- Bit [5]—C Cascade Mode → This bit enables cascade mode for int0 or int1 when set to 1.

- Bit [4]—LTM Level-Triggered Mode → The int0 or int1 interrupt may be edge- or level-triggered depending on the value of the bit. If LTM is 1, int0 or int1 is an active high-level-sensitive interrupt. If 0, either is a rising-edge-triggered interrupt and must remain active (high) until acknowledged.

- Bit [3]—MSK Mask → The int0 or int1 signal can cause an interrupt if the MSK bit is 0. If it is 1, they cannot. The Interrupt Mask Register has a duplicate of this bit.

- Bits [2–0]—PR2–PR0 Priority → These bits define the priority of the int0 or int1 in relation to other interrupt signals. The interrupt priority is the lowest at 7 at reset. The values of PR2–PR0 are shown above.

5.1.38 TCUCON (032h) (Master Mode)

Timer Control Unit Interrupt CONtrol Register. The three timers have their interrupts assigned to types 08h, 12h, and 13h and are configured by this register. The value of this register is 000Fh at reset (see Table 60).

Table 60. Timer Control Unit Interrupt Control Register

5.1.39 T2INTCON (03ah), T1INTCON (038h), and T0INTCON (032h) (Slave Mode)

Timer INTerrupt CONtrol Register. The three timers, Timer 2, Timer 1, and Timer 0, each have an interrupt control register, whereas in master mode all three are masked and prioritized in one register (TCUCON). The value of these registers is 000Fh at reset (see Table 61).

Table 61. Timer Interrupt Control Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												MSK	PR2–PR0		

- Bits [15–4]—Reserved → Set to 0.

- Bit [3]—MSK Mask → Any of the interrupt sources may cause an interrupt if the MSK bit is 0. If 1, they cannot. The Interrupt Mask Register has a duplicate of this bit.

- Bits [2–0]—PR2–PR0 Priority → These bits define the priority of the timer interrupts in relation to other interrupt signals. The interrupt priority is the lowest at 7 at reset. The values of PR2–PR0 are shown above.

5.1.40 DMA1CON (036h) and DMA0CON (034h) (Master Mode)

DMA CONtrol Register. The DMA0 and DMA1 interrupts have interrupt type 0ah and 0bh, respectively. The value of these registers is 000Fh at reset (see Table 62).

Table 62. DMA Interrupt Control Register (Master Mode)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												MSK	PR2–PR0		

- Bits [15–4]—Reserved → Set to 0.

- Bit [3]—MSK Mask → Any of the interrupt sources may cause an interrupt if the MSK bit is 0. If 1, they cannot. The Interrupt Mask Register has a duplicate of this bit.

- Bits [2–0]—PR2–PR0 Priority → These bits define the priority of the DMA interrupts in relation to other interrupt signals. The interrupt priority is the lowest at 7 at reset. The values of PR2–PR0 are shown above.

5.1.41 DMA1CON (036h) and DMA0CON (034h) (Slave Mode)

DMA CONtrol Register. The two DMA control registers maintain their original functions and addressing that they possessed in Master Mode. The value of these registers is 000Fh at reset (see Table 63).

Table 63. DMA and Interrupt Control Register (Slave Mode)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
				Reserved								MSK		PR2–PR0	

- Bits [15–4]—Reserved → Set to 0.

- Bit [3]—MSK Mask → Any of the interrupt sources may cause an interrupt if the MSK bit is 0. If 1, they cannot. The Interrupt Mask Register has a duplicate of this bit.

- Bits [2–0]—PR2–PR0 Priority → These bits define the priority of the DMA interrupts in relation to other interrupt signals. The interrupt priority is the lowest at 7 at reset. The values of PR2–PR0 are shown above.

5.1.42   INTSTS (030h) (Master Mode)

INTerrupt STatuS Register. The Interrupt status register contains the interrupt request status of each of the three timers, Timer 2, Timer 1, and Timer 0 (see Table 64).

Table 64. Interrupt Status Register (Master Mode)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DHLT					Reserved								TMR2–TMR0		

- Bit [15]—DHLT DMA Halt → DMA activity is halted when this bit is 1. It is set to 1 automatically when any non-maskable interrupt occurs and is cleared to 0 when an IRET instruction is executed. Interrupt handlers and other time-critical software may modify this bit directly to disable DMA transfers. However, the DHLT bit should not be modified by software if the timer interrupts are enabled as the function of this register because an interrupt request register for the timers would be compromised.

- Bits [14–3]—Reserved.

- Bits [2–0]—TMR2–TMR0 Timer Interrupt Request → A pending interrupt request is indicated by the corresponding timer, when any of these bits is 1.

Note: The TMR bit in the REQST register is a logical OR of these timer interrupt requests.

5.1.43   INTSTS (030h) (Slave Mode)

When nonmaskable interrupts occur, the interrupt status register controls DMA operation and the interrupt request status of each of the three timers, Timer 2, Timer 1, and Timer 0 (see Table 65).

Innovasic®

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DHLT	Reserved												TMR2–TMR0		

- Bit [15]—DHLT DMA Halt → DMA activity is halted when this bit is 1. It is set to 1 automatically when any non-maskable interrupt occurs and is cleared to 0 when an IRET instruction is executed.

- Bits [14–3]—Reserved.

- Bits [2–0]—TMR2–TMR0 Timer Interrupt Request → A pending interrupt request is indicated by the corresponding timer, when any of these bits is 1.

> *Note: The TMR bit in the REQST register is a logical OR of these timer interrupt requests.*

5.1.44 REQST (02eh) (Master Mode)

Interrupt REQueST Register. This is a read-only register and such a read results in the status of the interrupt request bits presented to the interrupt controller. The REQST register is undefined on reset (see Table 66).

Table 66. Interrupt Request Register (Master Mode)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved					SPI	WD	I4–I0					D1–D0		Reserved	TMR

- Bits [15–11]—Reserved.

- Bit [10]—SPI Serial Port Interrupt Request → This is the serial port interrupt state and when enabled is the logical OR of all the serial port 0 interrupt sources, THRE, RDR, BRKI, FER, PER, and OER.

- Bit [9]—WD Watchdog Timer Interrupt Request → When it is a 1, the watchdog interrupt state indicates that an interrupt is pending.

- Bits [8–4]—I4–I0 Interrupt Requests → When set to 1 indicates that the relevant interrupt has a pending interrupt.

- Bits [3–2]—D1–D0 DMA Channel Interrupt Request → When set to 1 indicates that the respective DMA channel has a pending interrupt.

- Bit [1]—Reserved.

- Bit [0]—TMR Timer Interrupt Request → This is the timer interrupt state and is the logical OR of the timer interrupt requests. When set to 1 indicates that the timer control unit has a pending interrupt.

5.1.45 REQST (02eh) (Slave Mode)

This is a read-only register and such a read results in the status of the interrupt request bits presented to the interrupt controller.

When an internal interrupt request (D1, D0, TMR2, TMR1, or TMR0) occurs, the respective bit is set to 1. The internally generated interrupt acknowledge resets these bits. The REQST register contains 0000h on reset (see Table 67).

Table 67. Interrupt Request Register (Slave Mode)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
					Reserved					TMR2	TMR1	D1–D0		Reserved	TMR0

- Bits [15–6]—Reserved.

- Bit [5]—TMR2 Interrupt Requests → When set to 1 indicates that Timer 2 has a pending interrupt.

- Bit [4]—TMR1 Interrupt Requests → When set to 1 indicates that Timer 1 has a pending interrupt.

- Bits [3–2]—D1–D0 DMA Channel Interrupt Request → When set to 1 indicates that the respective DMA channel has a pending interrupt.

- Bit [1]—Reserved.

- Bit [0]—TMR0 Timer Interrupt Request → When set to 1 indicates that Timer 0 has a pending interrupt.

5.1.46 INSERV (02ch) (Master Mode)

IN-SERVice Register. The interrupt controller sets the bits in this register when the interrupt is taken. Writing the corresponding interrupt type to the End-of-Interrupt (EOI) register clears each of these bits.

When one of these bits is set, an interrupt request will not be generated by the microcontroller for the respective source. This prevents an interrupt from interrupting itself if interrupts are enabled in the ISR. This restriction is bypassed in Special Fully nested mode for the int0 and int1 sources. The INSERV register contains 0000h on reset (see Table 68).

Table 68. In-Service Register (Master Mode)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved					SPI	WD	I4–I0					D1–D0		Reserved	TMR

- Bits [15–11]—Reserved.

- Bit [10]—SPI Serial Port Interrupt Request → This is the serial port 0 interrupt state.

- Bit [9]—WD Watchdog Timer Interrupt In-Service Request → This bit is the In-Service state of the Watchdog Timer.

- Bits [8–4]—I4–I0 Interrupt Requests → These bit indicate that the corresponding interrupt has a pending interrupt.

- Bits [3–2]—D1–D0 DMA Channel Interrupt In-Service → This bit is the In-Service state of the respective DMA channel.

- Bit [1]—Reserved.

- Bit [0]—TMR Timer Interrupt Request → This is the timer interrupt state and is the logical OR of the timer interrupt requests. When set to 1 indicates that the timer control unit has a pending interrupt.

5.1.47 INSERV (02ch) (Slave Mode)

This is a read-only register and such a read supplies the status of the interrupt request bits presented to the interrupt controller.

When an internal interrupt request (D1, D0, TMR2, TMR1, and TMR0) is serviced, the respective bit is set to 1. The in-service bits are reset by writing to the EOI register. The INSERV register contains 0000h on reset (see Table 69).

Table 69. In-Service Register (Slave Mode)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										TMR2	TMR1	D1–D0		Reserved	TMR0

- Bits [15–6]—Reserved.

- Bit [5]—TMR2 Timer 2 Interrupt In Service → Timer 2 is being serviced when this bit is set to 1.

- Bit [4]—TMR1 Timer 1 Interrupt In Service → Timer 1 is being serviced when this bit is set to 1.

- Bits [3–2]—D1–D0 DMA Channel Interrupt In Service → The respective DMA channel is being serviced when this bit is set to 1.

- Bit [1]—Reserved.

- Bit [0]—TMR0 Timer Interrupt In Service → Timer 0 is being serviced when this bit is set to 1.

5.1.48 PRIMSK (02ah) (Master and Slave Mode)

PRIority MaSK Register. This register contains a value that sets the minimum priority level at which an interrupt can be generated by a maskable interrupt. The PRIMSK register contains 0007h on reset (see Table 70).

Table 70. Priority Mask Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													PRM2–PRM0		

- Bits [15–3]—Reserved → Set to 0.

- Bits [2–0]—PRM2–PRM0 Priority Field Mask → This three-bit field sets the minimum priority necessary for a maskable interrupt to generate an interrupt. Any maskable interrupt with a numerically higher value than that contained by these three bits is masked. The values of PR2–PR0 are shown below.

  Values of PR2–PR0 by Priority

Priority	PR2–PR0
(High) 0	000b
1	001b
2	010b
3	011b
4	100b
5	101b
6	110b
(Low) 7	111b

  Any unmasked interrupt can generate an interrupt if the priority level is set to 7. On the other hand, if the priority level is set to 4, only unmasked interrupts with a priority of 0 to 4 are permitted to generate interrupts.

5.1.49 IMASK (028h) (Master Mode)

Interrupt MASK Register. The interrupt mask register is read/write. Setting a bit in this register sets the MSK bit in the corresponding interrupt control register. Setting a bit to 1 masks the

IA211110517-02

1-888-824-4184

interrupt. The interrupt request is enabled when the corresponding bit is set to 0. The IMASK register contains 07fdh on reset (see Table 71).

Table 71. Interrupt MASK Register (Master Mode)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
		Reserved			SPI	WD			I4–I0			D1–D0		Reserved	TMR

- Bits [15–11]—Reserved.

- Bit [10]—SPI Serial Port Interrupt Mask → Setting this bit to 1 indicates that the asynchronous serial port interrupt is masked.

- Bit [9]—WD Watchdog Timer Interrupt In-Service Request → Setting this bit to 1 indicates that the Watchdog Timer interrupt is masked.

- Bits [8–4]—I4–I0 Interrupt Mask → Setting any of these bits to 1 indicates that the relevant interrupt is masked.

- Bits [3–2]—D1–D0 DMA Channel Interrupt Mask → Setting this bit to 1 indicates that the respective DMA channel interrupt is masked.

- Bit [1]—Reserved.

- Bit [0]—TMR Timer Interrupt Mask → When set to 1, it indicates that the timer control unit interrupt is masked.

5.1.50 IMASK (028h) (Slave Mode)

Interrupt MASK Register. The interrupt mask register is read/write. Setting a bit in this register sets the MSK bit in the corresponding interrupt control register. Setting a bit to 1 masks the interrupt request. The interrupt request is enabled when the corresponding bit is set to 0. The IMASK register contains 003dh on reset (see Table 72).

Table 72. Interrupt MASK Register (Slave Mode)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
					Reserved					TMR2	TMR1	D1–D0		Reserved	TMR0

- Bits [15–6]—Reserved.

- Bit [5]—TMR2 Timer 2 Interrupt Mask → This bit indicates the state of the mask bit in the Timer Interrupt Control register. When set to 1, it indicates that the interrupt request is masked.

Innovasic®

Customer Support:
1-888-824-4184

- Bit [4]—TMR1 Timer 1 Interrupt Mask → This bit indicates the state of the mask bit in the Timer Interrupt Control register. When set to 1, it indicates that the interrupt request is masked.

- Bits [3–2]—D1–D0 DMA Channel Interrupt Mask → This bit indicates the state of the mask bit in the respective DMA channel Interrupt Control register. When set to 1, it indicates that the interrupt request is masked.

- Bit [1]—Reserved.

- Bit [0]—TMR0 Timer Interrupt Mask → This bit indicates the state of the mask bit in the Timer Interrupt Control register. When set to 1, it indicates that the interrupt request is masked.

5.1.51   POLLST (026h) (Master Mode)

POLL STatus Register. This register reflects the current state of the Poll register and can be read without affecting its contents. However, when the Poll Register is read, it causes the current interrupt to be acknowledged and replaced by the next interrupt. The poll status register is read-only (see Table 73).

Table 73. POLL Status Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IREQ	Reserved										S4–S0				

- Bit [15]—IREQ Interrupt Request → This bit is set to 1 when an interrupt is pending. During this state the S4–S0 bits contain valid data.

- Bits [14–5]—Reserved.

- Bits [4–0]—S4–S0 Poll Status → These bits show the interrupt type of the highest priority pending interrupt.

The interrupt service routine does not begin execution automatically with the IS bit set. Rather, the application software must execute the appropriate ISR.

5.1.52   POLL (024h) (Master Mode)

POLL Register. When the Poll Register is read, it causes the current interrupt to be acknowledged and be replaced by the next interrupt. The poll status register reflects the current state of the Poll register and can be read without affecting its contents. The POLL register is read-only (see Table 74).

Table 74. Poll Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IREQ	Reserved										S4–S0				

- Bit [15]—IREQ Interrupt Request → This bit is set to 1 when an interrupt is pending. During this state, the S4–S0 bits contain valid data.

- Bits [14–5]—Reserved.

- Bits [4–0]—S4–S0 Poll Status → These bits show the interrupt type of the highest priority pending interrupt.

5.1.53   EOI (022h) End-Of-Interrupt Register (Master Mode)

The In Service flags of the In-Service register are reset when a write is made to the EOI register. The interrupt service routine (ISR) should write to the EOI to reset the IS bit in the In-Service register for the interrupt before executing an IRET instruction that ends an interrupt service routine. Because it is most secure, the specific EOI reset is the preferred method for resetting the IS bits. The EOI register is write-only (see Table 75).

Table 75. End-of-Interrupt Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NSPEC	Reserved										S4–S0				

- Bit [15]—NSPEQ Non-Specific EOI → When set to 1, this bit is a non-specific EOI. When 0, it indicates the specific EOI.

- Bits [14–5]—Reserved.

- Bits [4–0]—S4–S0 Source Interrupt Type → These bits show the interrupt type of the interrupt being handled.

5.1.54   EOI (022h) Specific End-Of-Interrupt Register (Slave Mode)

A write clears the specific in-service flag indicated by L2-L0. The EOI register is write-only and undefined at reset (see Table 76).

Table 76. Specific End-of-Interrupt Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													L2–L0		

- Bits [15–3]—Reserved → Write as 0.

Customer Support:
1-888-824-4184

- Bits [2–0]—L2–L0 Interrupt Type → The priority or the IS (interrupt service) bit to be reset is encoded in these three bits. Writing to these bits caused the issuance of an EOI for the interrupt type (see Table 14, Interrupt Types).

5.1.55 INTVEC (020h) Interrupt Vector Register (Slave Mode)

The CPU shifts left 2 bits (multiplies by 4) an 8-bit interrupt type, generated by the interrupt controller, to produce an offset into the interrupt vector table. The INTVEC register is undefined at reset (see Table 77).

Table 77. Interrupt Vector Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								T4–T0					Reserved		

- Bits [15–8]—Reserved → Read as 0.

- Bits [7–3]—T4–T0 Interrupt Type → These five bits contain the five most significant bits of the interrupt types used for the internal interrupt type. The least significant three bits of the interrupt type are supplied by the interrupt controller, as set by the priority level of the interrupt request.

- Bits [2–0]—Reserved → Read as 0.

5.1.56 SSR (018h)

Synchronous Serial Receive Register. This register holds the serial data received on the SSI port. The value of the SSR register is undefined at reset (see Table 78).

Table 78. Synchronous Serial Receive Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								SR7-SR0							

- Bits [15–8]—Reserved.

- Bits [7–0]—SR7–SR0 → Data received over the SDATA pin.

5.1.57 SSD0 (016h) and SSD1 (014h)

Synchronous Serial Transmit Registers. These registers hold the data to be transmitted by the SSI ports. The value of these registers is undefined at reset (see Table 79).

Table 79. Synchronous Serial Transmit Registers

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								SD7–SD0

- Bits [15–8]—Reserved.

- Bits [7–0]—SD7–SD0 → Data to be transmitted over the SDATA pin.

5.1.58   SSC (012h)

Synchronous Serial Control Register. This register controls the operation of the sden1 and sden0 outputs and the baud rate of the SSI port. The sden1 and sden0 outputs are held high when the respective bit is set to 1, but in the event that both DE1 and DE0 are set to 1 then only sden0 will be held high. The value of the SSR register is 0000h at reset (see Table 80).

Table 80. Synchronous Serial Control Registers

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										SCLKDIV		Reserved		DE1	DE0

- Bits [15–6]—Reserved.

- Bits [5–4]—SCLKDIV SCLK Divide → These bits set the SCLK frequency. SCLK is the result of dividing the internal processor clock by 2, 4, 8, or 16 as shown below.

SCLKDIV	SCLK Frequency Divider
00b	Processor Clock/2
01b	Processor Clock/4
10b	Processor Clock/8
11b	Processor Clock/16

- Bits [3–2]—Reserved.

- Bit [1]—DE1 SDEN1 → The SDEN1 bit is held high when this bit is set to 1 and SDEN1 is held low when this bit is set to 0.

- Bit [0]—DE0 SDEN0 → The SDEN0 bit is held high when this bit is set to 1 and SDEN0 is held low when this bit is set to 0.

5.1.59   SSS (010h)

Synchronous Serial Status Register. This is a read-only register that indicates the state of the SSI port. The value of the SSR register is 0000h at reset (see Table 81).

Table 81. Synchronous Serial Status Registers

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

- Bits [15–3]—Reserved.

- Bit [2]—RE/TE Receive/Transmit Error Detect → This bit is set to 1 when a read of the Synchronous Serial Received register or a write to one of the transmit register is detected while the interface is busy (PB = 1). This bit is reset to 0 when the SDEN output is not active (DE1–DE0 in the SSC register are 00h).

- Bit [1]—DR/DT Data Receive/Transmit Complete → This bit is set to a 1 when the transmission of data Bit [7] is completed (SCLK rising edge) during a transmit or receive operation. This bit is reset by a read of the SSR register, when either the SSD0 or SSD1 register is written, when the SSS register is read (unless the SSI completes an operation and sets the bit in the same cycle), or when both SDEN0 and SDEN1 become inactive.

- Bit [0]—PB SSI Port Busy → This bit indicates that a data transmit or receive is occurring when it is set to 1. When set to 0, it indicates that the port is ready to transmit or receive data.

5.2   Reference Documents

Additional information on the operation and programming of the IA186ER/ IA188ER can be found in the following Advanced Micro Devices (AMD) publications:

- *Am186™ER and Am188™ER Microcontrollers User's Manual*, March 1998, Publication 21684, Rev B, Amendment/1.

- *Am186™ER and Am188™ER Data Sheet*, June 2000, Publication 20732, Rev. D, Amendment 0.

6.   AC Specifications

Table 82 presents the AC characteristics over industrial operating ranges (50 MHz). Tables 83 and 84 present the alphabetic and numeric keys to waveform parameters, respectively. Figure 11 presents the read cycle. Figure 12 presents the multiple read cycles. Table 85 presents the read cycle timing. Figure 13 presents the write cycle. Figure 14 presents the multiple write cycles. Table 86 presents the write cycle timing.

Figure 15 presents the PSRAM read cycle. Table 87 presents the PSRAM read cycle timing. Figure 16 presents the PSRAM write cycle. Table 88 presents the PSRAM write cycle timing. Figure 17 presents the PSRAM refresh cycle. Table 89 presents the PSRAM refresh cycle timing. Figure 18 presents the interrupt acknowledge cycle. Table 90 presents the interrupt acknowledge cycle timing. Figure 19 presents the software halt cycle. Table 91 presents the software halt cycle timing. Figure 20 presents the clock—active mode. Figure 21 presents the clock—power-save mode. Table 92 presents the clock timing.

Figure 22 presents the srdy—synchronous ready. Figure 23 presents the ardy—asynchronous ready. Figure 24 presents the peripherals. Table 93 presents the ready and peripheral timing. Figures 25 and 26 present Reset 1 and Reset 2, respectively. Figures 27 and 28 present the bus hold entering and bus hold leaving, respectively. Table 94 presents the reset and bus hold timing.

Figure 29 presents the synchronous serial interface. Table 95 presents the synchronous serial interface timing.

Table 97. Instruction Set Summary *(Continued)*

Instruction		Opcode - Hex			Flags Affected								
Mnemonic	Description	Byte 1	Byte 2	Bytes 3–6	O	D	I	T	S	Z	A	P	C
INSW	Input word from port in DX to ES:[DI]	6D											
INT 3	Generate interrupt 3 (trap to debug)	CC	–	–	–	–	0	0	–	–	–	–	–
INT	Generate type of interrupt specified by imm8	CD	ib	–									
INTO	Generate interrupt 4 if Overflow Flag (O) is 1	CE	–	–									
IRET	Interrupt return	CF	–	–	Restores value of flags reg that was stored on the stack when the interrupt was taken.								
JA	Jump short if above (C & Z = 0)	77	cb	–	–	–	–	–	–	–	–	–	–
JNBE	Jump short if not below or equal												
JAE	Jump short if above or equal (C=0)	73	cb	–	–	–	–	–	–	–	–	–	–
JNB	Jump short if not below (C=0)												
JNC	Jump short if not carry (C=0)												
JB	Jump short if below (C=1)	72	cb	–	–	–	–	–	–	–	–	–	–
JC	Jump short if carry (C=1)												
JNAE	Jump short if not above or equal (C=1)												
JBE	Jump short if below or equal (C & Z = 0)	76	cb	–	–	–	–	–	–	–	–	–	–
JNA	Jump short if not above (C & Z = 0)												
JCXZ	Jump short if CX reg is 0	E3	cb	–	–	–	–	–	–	–	–	–	–
JE	Jump short if equal (Z=1)	74	cb	–	–	–	–	–	–	–	–	–	–
JZ	Jump short if 0 (Z=1)												
JG	Jump short if greater (Z & S = O)	7F	cb	–	–	–	–	–	–	–	–	–	–
JNLE	Jump short if not less or equal (Z & S = O)												
JGE	Jump short if greater or equal (S=O)	7D	cb	–	–	–	–	–	–	–	–	–	–
JNL	Jump short if not less (S = O)												
JL/JNGE	Jump short if less (S ≠ O)	7C	cb	–	–	–	–	–	–	–	–	–	–
JLE	Jump short if less or equal (Z or S = O)	7E	cb	–	–	–	–	–	–	–	–	–	–
JNG	Jump short if not greater (Z or S = O)												
JMP	Jump short direct, disp relative to next instruction	EB	cb	–	–	–	–	–	–	–	–	–	–
	Jump near direct, disp relative to next instruction	E9	cw	–									
	Jump near indirect	FF	/4	–									
	Jump far direct to doubleword imm address	EA	cd	–									
	Jump m16: 16 indirect and far	FF	/5	–									
JNE	Jump short if not equal (Z=0)	75	cb	–	–	–	–	–	–	–	–	–	–
JNZ	Jump short if not zero (Z=0)												
JNO	Jump short if not overflow (O=1)	71	cb	–	–	–	–	–	–	–	–	–	–
JNP	Jump short if not parity (P=0)	7B	cb	–	–	–	–	–	–	–	–	–	–
JPO	Jump short if parity odd (P=0)												
JNS	Jump short if not sign (S=0)	79	cb	–	–	–	–	–	–	–	–	–	–
JO	Jump short if overflow (O=1)	70	cb	–	–	–	–	–	–	–	–	–	–
JP	Jump short if parity (P=1)	7A	cb	–	–	–	–	–	–	–	–	–	–
JPE	Jump short if parity (P=1)

Table 97. Instruction Set Summary *(Continued)*

Mnemonic	Description	Byte 1	Byte 2	Bytes 3–6	O	D	I	T	S	Z	A	P	C
MUL	AX = (r/m8) * AL	F6	/4	–	R	–	–	–	–	–	–	–	R
	DX::AX = (r/m16) * AX	F7	/4										
NEG	Perform 2's complement negation of r/m8	F6	/3	–	R	–	–	–	R	R	R	R	R
	Perform 2's complement negation of r/m16	F7	/3	–									
NOP	Perform no operation	90	–	–	–	–	–	–	–	–	–	–	–
NOT	Complement each bit in r/m8	F6	/2	–	–	–	–	–	–	–	–	–	–
	Complement each bit in r/m16	F7	/2										
OR	OR imm8 with AL	0C	ib	–	0	–	–	–	R	R	U	R	0
	OR imm16 with AX	0D	iw										
	OR imm8 with r/m8	80	/1	ib									
	OR imm16 with r/m16	81	/1	iw									
	OR imm8 with r/m16	83	/1	ib									
	OR byte reg with r/m8	08	/r	–									
	OR word reg with r/m16	09	/r	–									
	OR r/m8 with byte reg	0A	/r	–									
	OR r/m16 with word reg	0B	/r	–									
OUT	Output AL to imm port	E6	ib	–	–	–	–	–	–	–	–	–	–
	Output AX to imm port	E7	ib	–									
	Output AL to port in DX	EE	–	–									
	Output AX to port in DX	EF	–	–									
OUTS	Output byte DS:[SI] to port in DX	6E	–	–	–	–	–	–	–	–	–	–	–
	Output word DS:[SI] to port in DX	6F	–	–									
OUTSB	Output byte DS:[SI] to port in DX	6E	–	–									
OUTSW	Output word DS:[SI] to port in DX	6F	–	–									
POP	Pop top word of stack into memory word	8F	/0	–	–	–	–	–	–	–	–	–	–
	Pop top word of stack into word reg	58+rw	–	–									
	Pop top word of stack into DS	1F	–	–									
	Pop top word of stack into ES	07	–	–									
	Pop top word of stack into SS	17	–	–									
POPA	Pop DI, SI, BP, BX, DX, CX, & AX	61	–	–									
POPF	Pop top word of stack into Processor Status Flags reg	9D	–	–	Values in word at top of stack are copied into FLAGS reg bits.								
PUSH	Push memory word onto stack	FF	/6	–	–	–	–	–	–	–	–	–	–
	Push reg word onto stack	50+rw	–	–									
	Push sign-extended imm8 onto stack	6A	cb	–									
	Push imm16 onto stack	68	cw	–									
	Push CS onto stack	0E	–	–									
	Push SS onto stack	16	–	–									
	Push DS onto stack	1E	–	–									
	Push ES onto stack	06	–	–									
PUSHA	Push AX, CX, DX, BX, original SP, BP, SI, and DI	60	–	–	–	–	–	–	–	–	–	–	–

Table 97. Instruction Set Summary *(Continued)*

Instruction		Opcode - Hex			Flags Affected								
Mnemonic	Description	Byte 1	Byte 2	Bytes 3–6	O	D	I	T	S	Z	A	P	C
XCHG	Exchange word reg with AX	90	–	–	–	–	–	–	–	–	–	–	–
	Exchange AX with word reg	+rw	–	–									
	Exchange byte reg with r/byte	86	/r	–									
	Exchange r/m8 with byte reg		/r	–									
	Exchange word reg with r/m16	87	/r	–									
	Exchange r/m16 with word reg		/r	–									
XLAT	Set AL to memory byte segment :[BX+unsigned AL]	D7	–	–	–	–	–	–	–	–	–	–	–
XLATB	Set AL to memory byte DS :[BX+unsigned AL]	D7	–	–									
XOR	XOR imm8 with AL	34	ib	–	0	–	–	–	R	R	U	R	0
	XOR imm16 with AX	35	iw	–									
	XOR imm8 with r/m8	80	/6	ib									
	XOR imm16 with r/m16	81	/6	iw									
	XOR sign-extended imm8 with r/m16	83	/6	ib									
	XOR byte reg with r/m8	30	/r	–									
	XOR word reg with r/m16	31	/r	–									
	XOR r/m8 with byte reg	32	/r	–									
	XOR r/m16 with word reg	33	/r	–									

7.1 Key to Abbreviations Used in Instruction Set Summary Table

Abbreviations used in the Instruction Set Summary Table are explained below.

7.1.1 Operand Address Byte

The operand address byte is configured as shown below.

7	6	5	4	3	2	1	0
mod field		aux field			r/m field		

7.1.2 Modifier Field

The modifier field is defined below.

mod	Description
11	r/m is treated as a register field
00	DISP = 0, disp-low and disp-high are absent, address displacement is 0
01	DISP = disp-low sign-extended to 16-bits, disp-high is absent
10	DISP = disp-high:disp-low

7.1.3   Auxiliary Field

The Auxiliary Field is defined below.

aux	If mod = 11 and word = 0	If mod = 11 and word = 1
000	AL	AX
001	CL	CX
010	DL	DX
011	BL	BX
100	AH	SP
101	CH	BP
110	DH	SI
111	BH	DI

Note: When mod ≠ 11, depends on instruction.

7.1.4   r/m Field

The r/m field is defined below.

r/m	Description
000	EA = (BX) + (SI) + DISP [where EA is the Effective Address]
001	EA = (BX) + (DI) + DISP
010	EA = (BP) + (SI) + DISP
011	EA = (BX) + (DI) + DISP
100	EA = (SI) + DISP
101	EA = (DI) + DISP
110	EA = (BP) + DISP [except if mod = 00, then EA = disp-high:disp-low]
111	EA = (BX) + DISP

7.1.5   Displacement

The displacement is an 8- or 16-bit value added to the offset portion of the address.

7.1.6   Immediate Bytes

The immediate bytes consist of up to 16 bits of immediate data.

7.1.7   Segment Override Prefix

The segment override prefix is configured as shown below.

7	6	5	4	3	2	1	0
0	0	1	SR	SR	1	1	0

7.1.8 Segment Register

The segment register is shown below.

SR	Segment Register
00	ES
01	CS
10	SS
11	DS

7.2 Explanation of Notation Used in Instruction Set Summary Table

Notation used in the Instruction Set Summary Table is explained below.

Parameter	Indication
:	The component of the left is the segment for a component located in memory. The component on the right is the offset.
::	The component of the left is concatenated with the component on the right.

Operand	Definition
imm8	Immediate byte: signed number between –128 and 127
imm16	Immediate word: signed number between –32768 and 32767
m	Operand in memory
m8	Byte string in memory pointed to by DS:SI or ES:DI
m16	Word string in memory pointed to by DS:SI or ES:DI
r/m8	General byte register or a byte in memory
r/m16	General word register or a word in memory

7.2.1 Opcode

Opcode parameters and definitions are provided below.

Parameter	Definition
/0 - /7	The Auxiliary Field in the Operand Address byte specifies an extension (from 000 to 111, i.e., 0 to 7) to the opcode instead of a register. Thus, the opcode for adding (AND) an immediate byte to a general byte register or a byte in memory is "80 /4 ib." This indicates that the second byte of the opcode is "mod 100 r/m."
/r	The Auxiliary Field in the Operand Address byte specifies a register rather that an opcode extension. The opcode byte specifies which register, either byte size or word size, is assigned as in the aux code above.
/sr	This byte is placed before the instruction as shown in Section 7.1.7, Segment Override Prefix.
cb	The byte following the Opcode byte specifies the offset.
cd	The double word following the Opcode byte specifies the offset and a segment.

cw	The word following the Opcode byte specifies an offset or segment.
ib	Immediate byte—signed or unsigned determined by the Opcode byte.
iw	Immediate word—signed or unsigned determined by the Opcode byte.
rw	Word register operand as determined by the Opcode byte, aux field.

7.2.2   Flags Affected After Instruction

Flags affected after instruction are shown below.

U	Undefined
-	Unchanged
R	Result-dependent

8.   Innovasic/AMD Part Number Cross-Reference Table

Table 98. Innovasic/AMD Part Number Cross-Reference

Innovasic Part Number[1]	Package[2]	Grade	AMD Part Number (e.g. AM186ER-25KC\W)		
			Device Type	Speed Grade	Grade/Package Type
IA18xERPQF100IR2	100-Lead PQFP, RoHS Compliant	Industrial	AM186ER and AM188ER	25, 33, 40, 50	KC\W, KI\W[3]
IA18xERPLQ100IR2	100-Lead LQFP, RoHS Compliant	Industrial	AM186ER and AM188ER	25, 33, 40, 50	VC\W, VI\W[4] VD\W, VF\W

Notes:
1. Innovasic's part number for these devices is marked as "18x" to indicate the same device will be ordered for the 186 and 188 versions of that particular package style. Please refer to this data sheet for specific use of the pins for the 186 and 188 versions.
2. Innovasic is offering the ER in ONLY RoHS complaint packages.
3. AMD did not offer the PQFP in a RoHS compliant package. Customers desiring a replacement must switch to the RoHS compliant package.
4. Customers desiring a replacement for the non-RoHS LQFP must switch to the RoHS compliant package.

9.   Revision History

Table 99 includes the sequence of revisions to document IA211110517.

Table 99. Revision History

Date	Revision	Description	Page(s)
October 10, 2012	00	Initial Release	NA
December 12, 2012	01	Added min and max tolerances for LQFP package dimensions	22
February 25, 2013	02	Changed document number from ENG211110517 to IA211110517 to signify production release	All
		Corrected Innovasic Part Numbers	144
