Dual Digitally Controlled Potentiometer (XDCP ${ }^{\text {TM }}$ ) Low Noise, Low Power, SPI® Bus, 256 Taps

The ISL22424 integrates two digitally controlled potentiometers (DCP), control logic and non-volatile memory on a monolithic CMOS integrated circuit.

The digitally controlled potentiometers are implemented with a combination of resistor elements and CMOS switches. The position of the wiper is controlled by the user through the SPI serial interface. Each potentiometer has an associated volatile Wiper Register (WRi) and a non-volatile Initial Value Register (IVRi) that can be directly written to and read by the user. The contents of the WRi control the position of the wiper. At power-up the device recalls the contents of the DCP's IVRi to the corresponding WRi.

The ISL22424 also has 13 General Purpose non-volatile registers that can be used as storage of lookup table for multiple wiper position or any other valuable information.

The ISL22424 features a dual supply, that is beneficial for applications requiring a bipolar range for DCP terminals between V - and $\mathrm{V}_{\mathrm{CC}}$.
Each DCP can be used as three-terminal potentiometer or as two-terminal variable resistor in a wide variety of applications including control, parameter adjustments, and signal processing.

## Features

- Two potentiometers in one package
- 256 resistor taps
- SPI serial interface with write/read capability
- Daisy Chain Configuration
- Shutdown mode
- Non-volatile EEPROM storage of wiper position
- 13 General Purpose non-volatile registers
- High reliability
- Endurance: 1,000,000 data changes per bit per register
- Register data retention: 50 years @ $\mathrm{T} \leq+55^{\circ} \mathrm{C}$
- Wiper resistance: $70 \Omega$ typical @ 1 mA
- Standby current $<4 \mu \mathrm{~A}$ max
- Shutdown current $<4 \mu \mathrm{~A}$ max
- Dual power supply
- $\mathrm{V}_{\mathrm{CC}}=2.25 \mathrm{~V}$ to 5.5 V
- V - $=-2.25 \mathrm{~V}$ to -5.5 V
- $10 \mathrm{k} \Omega, 50 \mathrm{k} \Omega$ or $100 \mathrm{k} \Omega$ total resistance
- Extended industrial temperature range: $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
- 14 Ld TSSOP or 16 Ld QFN
- Pb-free plus anneal product (RoHS compliant)

## NOTES:

1. Intersil Pb-free plus anneal products employ special Pb -free material sets; molding compounds/die attach materials and $100 \%$ matte tin plate termination finish, which are RoHS compliant and compatible with both SnPb and Pb -free soldering operations. Intersil Pb -free products are MSL classified at Pb -free peak reflow temperatures that meet or exceed the Pb -free requirements of IPC/JEDEC J STD-020.
2. Add "-TK" suffix for 1,000 Tape and Reel option

NOTES:
4. Typical values are for $\mathrm{T}_{\mathrm{A}}=+25^{\circ} \mathrm{C}$ and 3.3 V supply voltage.
5. LSB: $\left[V(R W)_{255}-V(R W)_{0}\right] / 255 . V(R W)_{255}$ and $V(R W)_{0}$ are $V(R W)$ for the $D C P$ register set to $F F$ hex and 00 hex respectively. LSB is the incremental voltage when changing from one tap to an adjacent tap.
6. ZS error $=\mathrm{V}(\mathrm{RW})_{0} / \mathrm{LSB}$.
7. FS error $=\left[\mathrm{V}(\mathrm{RW})_{255}-\mathrm{V}_{\mathrm{CC}}\right] / \mathrm{LSB}$.
8. $D N L=\left[V(R W)_{i}-V(R W)_{i-1}\right] / L S B-1$, for $i=1$ to 255 . $i$ is the $D C P$ register setting.
9. $\operatorname{INL}=\left[V(R W)_{i}-i \cdot L S B-V(R W)\right] / L S B$ for $i=1$ to 255.
10. $\mathrm{V}_{\text {MATCH }}=[\mathrm{V}(\mathrm{RWx}) \mathrm{i}-\mathrm{V}(\mathrm{RWy}) \mathrm{i}] / \mathrm{LSB}$, for $\mathrm{i}=0$ to $255, \mathrm{x}=0$ to $1, \mathrm{y}=0$ to 1 .
11. $\mathrm{TC}_{\mathrm{V}}=\frac{\operatorname{Max}\left(\mathrm{V}(\mathrm{RW})_{\mathrm{i}}\right)-\operatorname{Min}\left(\mathrm{V}(\mathrm{RW})_{\mathrm{i}}\right)}{\left[\operatorname{Max}\left(\mathrm{V}(\mathrm{RW})_{\mathrm{i}}\right)+\operatorname{Min}\left(\mathrm{V}(\mathrm{RW})_{\mathrm{i}}\right)\right] / 2} \times \frac{10^{6}}{+165^{\circ} \mathrm{C}}$ for $\mathrm{i}=16$ to 240 decimal, $\mathrm{T}=-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$. Max ( $)$ is the maximum value of the wiper () is the minimum value of the wiper voltage over the temperature range.
12. $\mathrm{MI}=\left|\mathrm{RW}_{255}-\mathrm{RW}_{0}\right| 255$. MI is a minimum increment. $\mathrm{RW}_{255}$ and $\mathrm{RW} \mathrm{R}_{0}$ are the measured resistances for the DCP register set to FF hex and 00 hex respectively.
13. Roffset $=R W_{0} / M I$, when measuring between RW and RL. Roffset $=\mathrm{RW}_{255} / \mathrm{MI}$, when measuring between RW and RH .
14. $R D N L=\left(R W_{i}-R W_{i-1}\right) / M I-1$, for $i=1$ to 255 .
15. RINL $=\left[R W_{i}-(M I \cdot i)-R W_{0}\right] / M I$, for $i=1$ to 255.
16. $\mathrm{R}_{\text {MATCH }}=[(\mathrm{Rx}) \mathrm{i}-(\mathrm{Ry}) \mathrm{i}] / \mathrm{MI}$, for $\mathrm{i}=0$ to $255, \mathrm{x}=0$ to $1, \mathrm{y}=0$ to 1 .
18. $t_{W C}$ is the time from the end of a Write sequence of SPI serial interface, to the end of the self-timed internal non-volatile write cycle.
19. $R_{p u}$ is specified for the highest data rate transfer for the device. Higher value pull-up can be used at lower data rates.
20. This parameter is not $100 \%$ tested.

## Pin Description

## Potentiometer Pins

## RHI AND RLI

The high (RHi) and low (RLi) terminals of the ISL22424 are equivalent to the fixed terminals of a mechanical potentiometer. RHi and RLi are referenced to the relative position of the wiper and not the voltage potential on the terminals. With WRi set to 255 decimal, the wiper will be closest to RHi , and with the WRi set to 0 , the wiper is closest to RLi.

## RWI

RWi is the wiper terminal and is equivalent to the movable terminal of a mechanical potentiometer. The position of the wiper within the array is determined by the WRi register.

## Bus Interface Pins

## SERIAL CLOCK (SCK)

This is the serial clock input of the SPI serial interface.

## SERIAL DATA OUTPUT (SDO)

The SDO is a serial data output pin. During a read cycle, the data bits are shifted out on the falling edge of the serial clock SCK and will be available to the master on the following rising edge of SCK.

The output type is configured through ACR[1] bit for Push - Pull or Open Drain operation. Default setting for this pin is Push Pull. An external pull up resistor is required for Open Drain output operation. Note: the external pull up voltage not allowed beyond $\mathrm{V}_{\mathrm{C}}$.

## SERIAL DATA INPUT (SDI)

The SDI is the serial data input pin for the SPI interface. It receives device address, operation code, wiper address and data from the SPI remote host device. The data bits are shifted

FIGURE 14. LARGE SIGNAL SETTLING TIME
in at the rising edge of the serial clock SCK, while the $\overline{\mathrm{CS}}$ input is low.

## CHIP SELECT ( $\overline{\mathbf{C S}}$ )

$\overline{\mathrm{CS}}$ LOW enables the ISL22424, placing it in the active power mode. A HIGH to LOW transition on $\overline{\mathrm{CS}}$ is required prior to the start of any operation after power up. When $\overline{\mathrm{CS}}$ is HIGH, the ISL22424 is deselected and the SDO pin is at high impedance, and (unless an internal write cycle is underway) the device will be in the standby state.

## Principles of Operation

The ISL22424 is an integrated circuit incorporating two DCPs with their associated registers, non-volatile memory and the SPI serial interface providing direct communication between host, potentiometers and memory. The resistor arrays are comprised of individual resistors connected in a series. At either end of the array and between each resistor is an electronic switch that transfers the potential at that point to the wiper.

The electronic switches on the device operate in a "make before break" mode when the wiper changes tap positions.

When the device is powered down, the last value stored in IVRi will be maintained in the non-volatile memory. When power is restored, the content of the IVRi is recalled and loaded into the corresponding WRi to set the wiper to the initial position.

## DCP Description

Each DCP is implemented with a combination of resistor elements and CMOS switches. The physical ends of each DCP are equivalent to the fixed terminals of a mechanical potentiometer ( RHi and RLi pins). The RWi pin of the DCP is connected to intermediate nodes, and is equivalent to the wiper terminal of a mechanical potentiometer. The position of the wiper terminal within the DCP is controlled by an 8-bit volatile Wiper Register (WRi). When the WRi of a DCP contains all zeroes (WRi[7:0]=00h), its wiper terminal (RWi) is closest to its
"Low" terminal (RLi). When the WRi register of a DCP contains all ones (WRi[7:0]= FFh), its wiper terminal (RWi) is closest to its "High" terminal (RHi). As the value of the WRi increases from all zeroes (0) to all ones ( 255 decimal), the wiper moves monotonically from the position closest to RLi to the closest to RHi . At the same time, the resistance between RWi and RLi increases monotonically, while the resistance between RHi and RWi decreases monotonically.

While the ISL22424 is being powered up, the WRi is reset to 80h (128 decimal), which locates RWi roughly at the center between RLi and RHi. After the power supply voltage becomes large enough for reliable non-volatile memory reading, the WRi will be reloaded with the value stored in a corresponding nonvolatile Initial Value Register (IVRi).
The WRi and IVRi can be read or written to directly using the SPI serial interface as described in the following sections.

## Memory Description

The ISL22424 contains two non-volatile 8-bit Initial Value Registers (IVRi), thirteen non-volatile 8-bit General Purpose (GP) registers, two volatile 8-bit Wiper Registers (WRi), and volatile 8-bit Access Control Register (ACR). The memory map of ISL22424 is in Table 1.

TABLE 1. MEMORY MAP

| ADDRESS <br> (hex) | NON-VOLATILE | VOLATILE |
| :---: | :---: | :---: |
| 10 | N/A | ACR |
| F | Reserved |  |
| E | General Purpose | N/A |
| D | General Purpose | N/A |
| C | General Purpose | N/A |
| $B$ | General Purpose | N/A |
| $A$ | General Purpose | N/A |
| 9 | General Purpose | N/A |
| 8 | General Purpose | N/A |
| 7 | General Purpose | N/A |
| 6 | General Purpose | N/A |
| 5 | General Purpose | N/A |
| 4 | General Purpose | N/A |
| 3 | General Purpose | N/A |
| 2 | General Purpose | WR1 |
| 1 | IVR1 | IVR0 |
| 0 |  |  |

The non-volatile registers (IVRi) at address 0 and 1, contain initial wiper position and volatile registers (WRi) contain current wiper position.

The register at address 0Fh is a read-only reserved register. Information read from this register should be ignored.
The non-volatile IVRi and volatile WRi registers are accessible with the same address.

The Access Control Register (ACR) contains information and control bits described below in Table 2.
The VOL bit (ACR[7]) determines whether the access to wiper registers WRi or initial value registers IVRi.

TABLE 2. ACCESS CONTROL REGISTER (ACR)

| BIT \# | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| BIT <br> NAME | VOL | SHDN | WIP | 0 | 0 | 0 | SDO | 0 |

If VOL bit is 0 , the non-volatile IVRi and General Purpose registers are accessible. If VOL bit is 1 , only the volatile WRi are accessible. Note: value that is written to IVRi register also is written to the corresponding WRi. The default value of this bit is 0 .
The $\overline{\mathrm{SHDN}}$ bit (ACR[6]) disables or enables Shutdown mode. When this bit is $0, D C P$ is in Shutdown mode, i.e. each DCP is forced to end-to-end open circuit and RWi is shorted to RLi as shown on Figure 15. Default value of $\overline{\text { SHDN }}$ bit is 1.

FIGURE 15. DCP CONNECTION IN SHUTDOWN MODE
Setting $\overline{\mathrm{SHDN}}$ bit to 1 is returned wipers to prior to Shutdown Mode position.

The WIP bit (ACR[5]) is a read-only bit. It indicates that nonvolatile write operation is in progress. The WIP bit can be read repeatedly after a non-volatile write to determine if the write has been completed. It is impossible to write or read to the WRi or ACR while WIP bit is 1 .
The SDO bit (ACR[1]) configures type of SDO output pin. The default value of SDO bit is 0 for Push - Pull output. SDO pin can be configured as Open Drain output for some application. In this case, an external pull up resistor is required. See "Applications Information" on page 15.

## SPI Serial Interface

The ISL22424 supports an SPI serial protocol, mode 0 . The device is accessed via the SDI input and SDO output with data clocked in on the rising edge of SCK, and clocked out on the falling edge of SCK. $\overline{C S}$ must be LOW during communication with the ISL22424. SCK and $\overline{\mathrm{CS}}$ lines are controlled by the host or master. The ISL22424 operates only as a slave device.

All communication over the SPI interface is conducted by sending the MSB of each byte of data first.

## Protocol Conventions

The SPI protocol contains Instruction Byte followed by one or more Data Bytes. A valid Instruction Byte contains instruction as the three MSBs, with the following five register address bits (see Table 3).

The next byte sent to the ISL22424 is the Data Byte.
TABLE 3. INSTRUCTION BYTE FORMAT

| BIT \# | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | I 2 | I 1 | IO | R 4 | R 3 | R 2 | R 1 | R 0 |

Table 4 contains a valid instruction set for ISL22424.
There are only sixteen register addresses possible for this DCP. If the [R4:R0] bits are 00000 or 00001, then the read or write is to either the IVRi or the WRi registers (depends of VOL bit at ACR). If the [R4:R0] are 10000, then the operation is on the ACR.

## Write Operation

A Write operation to the ISL22424 is a two or more bytes operation. First, It requires, the $\overline{\mathrm{CS}}$ transition from HIGH to

LOW. Then host must send a valid Instruction Byte followed by one or more Data Bytes to SDI pin. The host terminates the write operation by pulling the $\overline{\mathrm{CS}}$ pin from LOW to HIGH. Instruction is executed on rising edge of $\overline{\mathrm{CS}}$. For a write-to address 0 or 1, the MSB of the byte at address 10h (ACR[7]) determines if the Data Byte is to be written to volatile or both volatile and non-volatile registers. Refer to "Memory Description" and Figure 16. Note: the internal non-volatile write cycle starts with the rising edge of $\overline{C S}$ and requires up to 20 ms . During non-volatile write cycle the read operation to ACR register is allowed to check WIP bit.

## Read Operation

A Read operation to the ISL22424 is a four byte operation. It requires first, the $\overline{\mathrm{CS}}$ transition from HIGH to LOW. Then the host must send a valid Instruction Byte followed by "dummy" Data Byte, a NOP Instruction Byte and another "dummy" Data Byte to SDI pin. The SPI host receives the Instruction Byte (instruction code + register address) and requested Data Byte from SDO pin on rising edge of SCK during third and fourth bytes respectively. The host terminates the read operation by pulling the $\overline{\mathrm{CS}}$ pin from LOW to HIGH (see Figure 17). Reading from the IVRi will not change the WRi, if its contents are different.

TABLE 4. INSTRUCTION SET

| INSTRUCTION SET |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :--- |
| $\mathbf{I 2}$ | $\mathbf{I 1}$ | $\mathbf{I 0}$ | R4 | R3 | R2 | R1 | R0 |  |
| 0 | 0 | 0 | X | X | X | X | X | NOP |
| 0 | 0 | 1 | X | X | X | X | X | ACR READ |
| 0 | 1 | 1 | X | X | X | X | X | ACR WRITE |
| 1 | 0 | 0 | R 4 | R 3 | R 2 | R 1 | R 0 | WR, IVR, GP or ACR READ |
| 1 | 1 | 0 | R 4 | R 3 | R 2 | R 1 | R0 | WR, IVR, GP or ACR WRITE |

where X means "do not care".

FIGURE 16. TWO BYTE WRITE SEQUENCE

FIGURE 17. FOUR BYTE READ SEQUENCE

## Applications Information

## Communicating with ISL22424

Communication with ISL22424 proceeds using SPI interface through the ACR (address 10000b), IVRi (address 00000b, 00001b), WRi (addresses 00000b, 00001b) and General Purpose registers (addresses from 00010b to 01110b).

The wiper position of each potentiometer is controlled by the corresponding WRi register. Writes and reads can be made directly to these registers to control and monitor the wiper position without any non-volatile memory changes. This is done by setting MSB bit at address 10000b to 1 (ACR[7] = 1).
The non-volatile IVRi stores the power up position of the wiper. IVRi is accessible when MSB bit at address 10000b is set to 0 (ACR[7] = 0). Writing a new value to the IVRi register will set a new power up position for the wiper. Also, writing to this registers will load the same value into the corresponding WRi as the IVRi. Reading from the IVRi will not change the WRi, if its contents are different.

## Daisy Chain Configuration

When application needs more then one ISL22424, it can communicate with all of them without additional $\overline{\mathrm{CS}}$ lines by daisy chaining the DCPs as shown on Figure 18. In Daisy Chain configuration the SDO pin of previous chip is connected to SDI pin of the following chip, and each $\overline{\mathrm{CS}}$ and SCK pins are connected to the corresponding microcontroller pins in parallel, like regular SPI interface implementation. The Daisy Chain configuration can also be used for simultaneous setting of multiple DCPs. Note, the number of daisy chained DCPs is limited only by the driving capabilities of SCK and $\overline{\mathrm{CS}}$ pins of microcontroller; for larger number of SPI devices buffering of SCK and $\overline{\mathrm{CS}}$ lines is required.

## Daisy Chain Write Operation

The write operation starts by HIGH to LOW transition on $\overline{\mathrm{CS}}$ line, followed by N two bytes write instructions on SDI line with reversed chain access sequence: the instruction byte + data byte for the last DCP in chain is going first, as shown on Figure 19. The serial data is going through DCPs from DCPO to DCP(N-1) as follow: DCP0 --> DCP1 --> DCP2 --> ... -->
$\mathrm{DCP}(\mathrm{N}-1)$. The write instruction is executed on the rising edge of $\overline{\mathrm{CS}}$ for all NDCPs simultaneously.

## Daisy Chain Read Operation

The read operation consists of two parts: first, send read instructions ( N two bytes operation) with valid address; second, read the requested data while sending NOP instructions ( N two bytes operation) as shown on Figure 20 and Figure 21.
The first part starts by HIGH to LOW transition on $\overline{\mathrm{CS}}$ line, followed by N two bytes read instruction on SDI line with reversed chain access sequence: the instruction byte + dummy data byte for the last DCP in chain is going first, followed by LOW to HIGH transition on $\overline{\mathrm{CS}}$ line. The read instructions are executed during second part of read sequence. It also starts by HIGH to LOW transition on $\overline{\mathrm{CS}}$ line, followed by N two bytes NOP instructions on SDI line and LOW to HIGH transition of $\overline{\mathrm{CS}}$. The data is read on every even byte during second part of read sequence while every odd byte contains instruction code + address from which the data is being read.

## Wiper Transition

When stepping up through each tap in voltage divider mode, some tap transition points can result in noticeable voltage transients, or overshoot/undershoot, resulting from the sudden transition from a very low impedance "make" to a much higher impedance "break within an extremely short period of time (<50ns). Two such code transitions are EFh to FOh, and OFh to 10h. Note, that all switching transients will settle well within the settling time as stated on the datasheet. A small capacitor can be added externally to reduce the amplitude of these voltage transients, but that will also reduce the useful bandwidth of the circuit, thus may not be a good solution for some applications. It may be a good idea, in that case, to use fast amplifiers in a signal chain for fast recovery.

## Application Example

Figure 22 shows an example of using ISL22424 for gain setting and offset correction in high side current measurement application. DCPO applies a programmable offset voltage of $\pm 25 \mathrm{mV}$ to the FB+ pin of the Instrumentation Amplifier EL8173 to adjust output offset to zero voltages. DCP1 programs the
gain of the EL8173 from 90 to 110 with 5 V output for 10A current through current sense resistor.

More application examples can be found at http://www.intersil.com/data/an/AN1145.pdf
