LTC3546

# Dual Synchronous, 3A/1A or 2A/2A Configurable Step-Down DC/DC Regulator 

## feATURES

- $\mathrm{V}_{\text {IN }}$ Range: 2.25 V to 5.5 V
- $V_{\text {OUt }}$ Range: 0.6 V to 5 V
- Programmable Frequency Operation; 2.25MHz, or Adjustable Between 0.75 MHz to 4 MHz
- Low R RS(ON $)^{\text {Internal Switches }}$
- High Efficiency: Up to 96\%
- No Schottky Diodes Required
- Short-Circuit Protected
- Current Mode Operation for Excellent Line and Load Transient Response
- Low Ripple Burst Mode Operation (30mVp-p), $I_{0}=160 \mu \mathrm{~A}$
- Ultralow Shutdown Current: $\mathrm{I}_{\mathrm{Q}}<1 \mu \mathrm{~A}$
- Low Dropout Operation: 100\% Duty Cycle
- Power Good Output For Each Channel
- Externally or Internally Programmable Burst Level
- External or Internal Soft-Start or Supply Tracking
- Available in Thermally Enhanced 28-Lead $(4 \mathrm{~mm} \times 5 \mathrm{~mm})$ QFN and TSSOP Packages

## APPLICATIONS

- Netbooks/Ultra-Mobile PCs
- PC Cards
- Wireless and DSL Modems
- Point of Load DC/DC Conversion

## DESCRIPTIOn

The LTC®3546 is a dual, constant-frequency, synchronous step down $\mathrm{DC} / \mathrm{DC}$ converterfor medium power applications. The design consists of 2 A and 1 A primary outputswitches. In addition to the 2A/1A capability, a 1 A dependant output switch can be externally connected to either of the primary outputs to produce $3 \mathrm{~A} / 1 \mathrm{~A}$ dual regulator or $2 \mathrm{~A} / 2 \mathrm{~A}$ dual regulator configurations.
Supply operation is from 2.25 V to 5.5 V . The switching frequency can be set to 2.25 MHz , adjustable from 0.75 MHz to 4 MHz , or synchronized to an external clock. Each output is adjustable from 0.6 V to 5 V and has output tracking on power-up. Internal synchronous low $\mathrm{R}_{\mathrm{DS}(\mathrm{ON})}$ power switches provide high efficiency without external Schottky diodes.

User-selectable modes (Burst Mode ${ }^{\circledR}$ operation, pulse skipping and forced continuous) allow a trade-off between ripple noise and power efficiency. Burst Mode operation provides high efficiency at light loads. Pulse-skipping mode provides low ripple noise at light loads.
The device is capable of low dropout configurations and both channels can operate at $100 \%$ duty cycle. In shutdown, the device draws <1 $\mu \mathrm{A}$.
$\boldsymbol{\Sigma}$, LT, LTC, LTM, Linear Technology, the Linear logo and Burst Mode are registered trademarks of Linear Technology Corporation. All other trademarks are the property of their respective owners. Protected by U.S. Patents, including 5481178, 6611131, 6304066, 6498466, 6580258.

## TYPICAL APPLICATION

$V_{\text {OUT2 }}$ Efficiency (Burst Mode Operation)

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.
Note 2: The LTC3546 is tested under pulsed load conditions such that $T_{J} \approx T_{A}$. The LTC3546E is guaranteed to meet performance specifications from $0^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$. Specifications over the $-40^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$ operating junction temperature range are assured by design, characterization and correlation with statistical process controls. The LTC3546I is guaranteed to meet performance specifications over the full $-40^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$ operating junction temperature range. The maximum ambient temperature consistent with these specifications is determined by specific operating conditions in conjunction with board layout, the rated package thermal impedance and other environmental factors.
Note 3: The LTC3546 is tested in feedback loop which servos $\mathrm{V}_{\text {FB1 }}$ to the midpoint for the error amplifier $\left(\mathrm{V}_{\text {ITH1 }}=0.6 \mathrm{~V}\right)$ and $\mathrm{V}_{\mathrm{FB} 2}$ to the midpoint for the error amplifier ( $\mathrm{V}_{\text {ITH2 }}=0.6 \mathrm{~V}$ ).

Note 4: Total supply current is higher due to the internal gate charge being delivered at the switching frequency.
Note 5: Variable frequency operation with resistor is guaranteed by design and is subject to duty cycle limitations.
Note 6: This IC includes overtemperature protection that is intended to protect the device during momentary overload conditions. Junction temperature will exceed $125^{\circ} \mathrm{C}$ when overtemperature protection is active. Continuous operation above the specified maximum operating junction temperature may impair device reliability.
Note 7: $T_{j}$ is calculated from the ambient temperature, $T_{A}$, and power dissipation, $\mathrm{P}_{\mathrm{D}}$, according to the following formula:

$$
T_{J}=T_{A}+\left(P_{D} \cdot 34^{\circ} \mathrm{C} / \mathrm{W}\right)
$$

Note 8: Minimum current limit is guaranteed by design and correlation to the $\mathrm{R}_{\mathrm{DS}(\mathrm{ON}) 1 \mathrm{D}}$, $\mathrm{L}_{\mathrm{LIM} 1}$ and $\mathrm{I}_{\mathrm{LIM} 2}$ measurements.

## PIn fUnCTIONS (UFD/FE)

BMC2 (Pin 1/Pin 4): Burst Mode Clamp for Channel 2. Connecting this pin to an external voltage between OV and 0.6 V sets the Burst Mode clamp level. If this pin is pulled to $\mathrm{V}_{\text {ccA }}$, an internal Burst Mode clamp level is used. This pin should be tied to GND when Burst Mode operation is not selected.

TRACK/SS2 (Pin 2/Pin 5): Tracking input for Channel 2 output or optional external soft-start input. Vout2 will track an external voltage at this pin. Leaving this pin floating allows $\mathrm{V}_{\text {OUT2 } 2}$ to start-up using the internal soft-start. An external soft-start can be programmed by connecting a capacitor between this pin and ground. External soft-start ramp time must be greater than the internal soft-start time of 1.2 ms . Refer to the Applications Information section for more details.
$V_{\text {FB2 }}$ (Pin 3/Pin 6): Feedback voltage from external resistive divider from the Channel 2 regulator output. Nominal voltage for this pin is 0.6 V .
$I_{\text {TH2 }}$ (Pin 4/Pin 7): Error AmplifierCompensation for Channel 2 Regulator. Peak current increases with an increase in the voltage on this pin. Nominal voltage range for this pin is 0 V to 1.5 V .
$V_{\text {cco }}$ (Pin 5/Pin 8): Supply Pin for Internal Digital Circuitry.
RUN2 (Pin 6/Pin 9): Low Level Logic Input. Enable for Channel 2 . When pulled high, regulator is running. When at OV, regulator is off. When both RUN1 and RUN2 are at OV the part is in shutdown.
$\mathrm{V}_{\text {IN2 }}$ (Pin 7/Pin 10): Supply pin for 2A P-channel switch which connects from $\mathrm{V}_{\mathbb{I N} 2}$ to $\mathrm{SW} 2 \mathrm{~A} / \mathrm{B}$.
$\mathrm{V}_{\mathrm{IN} 1}$ (Pin 8/Pin 11): Supply pin for 1A P-channel switch which connects from $\mathrm{V}_{\text {IN1 }}$ to SW 1 .
$\mathrm{V}_{\text {IN1D }}$ (Pin 9/Pin 12): Supply pinfor 1AdependentP-channel switch which connects from $V_{\text {IN1D }}$ to $S W 1 D$.
SW2A (Pin 10/Pin 13): Half of the switch node connection to the inductor for Channel 2. SW2A and SW2B must be externally tied together. This pin swings from $\mathrm{V}_{\text {IN2 }}$ to PGND2.

SW2B (Pin 11/Pin 14): Half of the switch node connection to the inductor for Channel 2 SW2A and SW2B must be externally tied together. This pin swings from $\mathrm{V}_{\text {IN2 }}$ to PGND2.

SW1D (Pin 12/Pin 15): The Dependent Switch Node Connection. The pin is externally connected to SW1 for a 2A/2A regulator or to SW2A/B for a 3A/1A regulator. Internal circuitry detects which pin SW1D is externally connected to, SW1 or SW2A/B. This pin swings from $\mathrm{V}_{\text {IN1D }}$ to PGND1D. SW1D switching will be controlled by the output switch to which it is connected, i.e., SW1 or SW2A/SW2B. The dependant 1A power stage can be disabled by floating the SW1D pin. The SW1D pin must never be connected to $\mathrm{V}_{\text {IN }}$ or GND. When disabled, SW1D is pulled high internally.
SW1 (Pin 13/Pin 16): The switch node connection to the Inductor for the Channel 1 regulator. This pin swings from $\mathrm{V}_{\text {IN1 }}$ to PGND1.
PGND1D (Pin 14/Pin 17): Ground for SW1D Switching N-Channel Driver.

PGND1 (Pin 15/Pin 18): Ground for SW1 Switching NChannel Driver.
PGND2 (Pin 16/Pin 19): Ground for SW2A and SW2B Switching N-Channel Driver.

RUN1 (Pin 17/Pin 20): Low Level Logic Input. Enable for Channel 1. When pulled high, regulator is running. When at 0 V , regulator is off. When both RUN1 and RUN2 are at OV the part is in shutdown.
PHASE (Pin 18/Pin 21): Low Level Logic Input. Selects Channel 2 regulator switching phase with respect to Channel 1 regulator switching. When pulled high, the SW1 regulator and the SW2A/B regulator are in phase. When PHASE is at OV the SW1 regulator and the SW2A/B regulator are switching $180^{\circ}$ out-of-phase.
ITH1 (Pin 19/Pin 22): Error Amplifier Compensation for Channel 1. Peak current increases with an increase in the voltage on this pin. Nominal voltage range for this pin is OV to 1.5 V .

## PIn fUnCTIONS (UFD/FE)

$\mathbf{V}_{\text {FB1 }}$ (Pin 20/Pin 23): Feedback voltage from external resistive divider from Channel 1 output. Nominal voltage for this pin is 0.6 V .
TRACK/SS1 (Pin 21/Pin 24): Tracking input for Channel 1 output or optional external soft-start input. VOUT1 will track an external voltage at this pin. Leaving this pin floating allows $\mathrm{V}_{\text {OUT1 }}$ to start-up using the internal soft-start. An external soft-start can be programmed by connecting a capacitor between this pin and ground. External soft-start ramp time must be greater than the internal soft-start time of 1.2 ms . Refer to the Applications Information section for more details.

BMC1 (Pin 22/Pin 25): Burst Mode Clamp for Channel 1. Connecting this pin to an external voltage between 0 V and 0.6 V sets the Burst Mode clamp level. If this pin is pulled to $V_{\text {CCA }}$, an internal Burst Mode clamp level is used. This pin should be tied to GND when Burst Mode operation is not selected.

PG00D1 (Pin 23/Pin 26): Power Good Pin for the 1A Regulator. This common drain logic output is pulled to GND when the output voltage of Channel 1 is below -8\% of regulation.
FREQ (Pin 24/Pin 27): Frequency Set Pin. When FREQ is at $\mathrm{V}_{\text {CCA }}$, the internal oscillator runs at 2.25 MHz . When a resistor is connected from this pin to GNDA, the internal oscillator frequency can be varied from 0.75 MHz to 4 MHz .

When using external synchronization this pin compensates the internal PLL. Typical compensation components are a 200k resistor in series with a 100pF capacitor.

GNDA (Pin 25/Pin 28): Ground Pin for Internal Analog Circuitry.
$\mathbf{V}_{\text {CCA }}$ (Pin 26/Pin 1): Supply Pin for Internal Analog Circuitry.

SYNC/MODE (Pin 27/Pin 2): Combination Mode Selection and Oscillator Synchronization Pin. This pin controls the operation of the device. When the voltage on the SYNC/MODE pin is $>\left(\mathrm{V}_{\mathrm{IN}}-0.5 \mathrm{~V}\right)$, Burst Mode operation is selected for both regulators. When the voltage on the SYNC/MODE pin is $<0.5 \mathrm{~V}$, pulse-skipping mode is selected for both regulators. When the SYNC/MODE pin is held at $V_{\text {IN }} / 2$, forced continuous mode is selected for both regulators. The oscillation frequency can be synchronized to an external oscillator applied to this pin. When synchronized to an external clock, pulse-skipping mode is selected.

PGOOD2 (Pin 28/Pin 3): Power Good Pin for Channel 2 This common drain logic output is pulled to GND when the output voltage of Channel 2 is below $-8 \%$ of regulation.
GNDD (Exposed Pad Pin 29/Exposed Pad Pin 29): Digital Ground. Connect to Electrical Ground for substrate and internal digital circuitry. Solder to PCB for rated thermal performance.
functional dingram

## OPERATION

The LTC3546 uses a constant-frequency, currentmodearchitecture. Both channels share the same clock frequency. The PHASE pin sets whether the channels are running in-phase, or $180^{\circ}$ out-of-phase. The operating frequency is determined by connecting the FREQ pinto $\mathrm{V}_{\text {IN }}$ for 2.25 MHz operation or by connecting a resistor from FREQto GNDA for frequencies between 0.75MHz to 4MHz. A 143k resistor to GNDA will set the frequency to 1.5 MHz . The part can also be synchronized to an external clock through the SYNC/MODE pin. To suit a variety of applications, the selectable SYNC/MODE pin allows the user to trade-off noise for efficiency.
The output voltages are set by external dividers returned to the $\mathrm{V}_{\mathrm{FB} 1}$ and $\mathrm{V}_{\mathrm{FB} 2}$ pins. An error amplifier compares the divided output voltage with a reference voltage of 0.6 V and adjusts an internal peak inductor current setting accordingly. Peak inductor current during Burst Mode operation can also be set externally through the BMC1 and BMC2 pins. Undervoltage comparators will pull the PGOOD1 or PGOOD2 outputs low when their respective outputs drop below $-8 \%$ of the set output voltage.
The TRACK/SS pins allow for controlled start-up via an externally or internally generated voltage ramp. It can also track an externally applied voltage.
A1A dependent switch, SW1D, can be externally connected to the SW1 output or the SW2A/SW2B output. Internal circuitry auto detects which output SW1D is connected to and controls them accordingly. With this flexibility, the LTC3546 can be configured as either a 2A/2A dual regulator (when SW1D is connected to SW1) or as a 3A/1A dual regulator (when SW1D is connected to SW2A/SW2B).

## Main Control Loop

For each regulator, during normal operation, the P-channel MOSFET power switch is turned on at the beginning of a clock cycle when the $\mathrm{V}_{\mathrm{FB}}$ voltage is below the 0.6 V reference voltage. The current into the inductor and the load increases until the current limit is reached. The switch turns off and energy stored in the inductor flows through the bottom N-channel MOSFET switch into the load until the next clock cycle.

The peak inductor current is controlled by the voltage on the $I_{\text {TH }}$ pin, which is the output of the 2.5 MHz bandwidth error amplifier. The error amplifier compares the $V_{F B}$ pin to the 0.6 V reference. When the load current increases, the $\mathrm{V}_{\mathrm{FB}}$ voltage decreases slightly below the reference. This decrease causes the error amplifier to increase the $\mathrm{I}_{\mathrm{TH}}$ voltage until the average inductor current matches the new load current.

The main control loop is shut down by pulling the RUN pin to ground. When the RUN pin is pulled high, the control loop goes through start-up. Start-up is dependent on the TRACK/SS pin. If TRACK/SS is left floating, an internal soft-start is enabled which will ramp up the output voltage to the desired level in 1.2 ms . The output voltage will track the voltage on its associated TRACK/SS pin. If the TRACK/SS pin is connected through a resistor divider from another supply, such as the output voltage from the other LTC3546 regulator, the output voltage will track this supply thus allowing the LTC3546 output voltage to track the other supply start-up. If a capacitor is connected from the TRACK/SS pin to ground, when RUN goes high, an internal $1.15 \mu \mathrm{~A}$ current source will charge the external capacitor controlling the output voltage start-up. Care must be taken to make sure the external start-up ramp time is greater than the 1.2 ms internal start-up time.

## Low Current Operation

Three modes are available to control the operation of the LTC3546 at low currents. All three modes automatically switch from continuous operation to the selected mode when the load current is low.
To optimize efficiency, BurstMode operation can be selected. When the load is relatively light, the LTC3546 automatically switches into Burst Mode operation in which the switches operate intermittently based on load demand. By running cycles periodically, the switching losses which are dominated by the gate charge losses of the power MOSFETs are minimized. The main control loop is interrupted when the output voltage reaches the desired regulated value.
A voltage comparator with hysteresis trips when $I_{T H}$ is below 0.24 V , shutting off the switches and reducing the power.

## OPERATION

The output capacitor and the inductor supply the power to the load until $I_{T H}$ exceeds 0.31 V , turning on the switch and the main control loop which starts another cycle.

The Burst Mode peak inductor current can be set externally via the BMC pin. When this pin is set somewhere between 0 V to 0.6 V , the voltage on this pin controls the Burst Mode clamp level. When the BMC pin is pulled to $\mathrm{V}_{\mathrm{IN}^{\prime}}$, an internal Burst Mode clamp level is used.

For lower output voltage ripple at low currents, pulseskipping mode can be used. In this mode, the LTC3546 continues to switch at constant frequency down to very low currents, where it will eventually begin skipping pulses.
Finally, in forced continuous mode, the inductor current is constantly cycled which creates a fixed output voltage ripple at all output current levels. This feature is desirable in telecommunications since the noise is a constant frequency and is thus easyto filter out. Another advantage of this mode is that the regulator is capable of both sourcing current into a load and sinking some current from the output. In forced
continuous operation, an overvoltage comparator monitors the $V_{F B}$ pin and decreases the current limit whenever an overvoltage condition is detected ( $\mathrm{V}_{\mathrm{FB}}>0.63 \mathrm{~V}$ ).
The SYNC/MODE pin selects what mode the LTC3546 is in. The SYNC/MODE pin sets the mode for both regulators.

## Dropout Operation

When the input supply voltage decreases toward the output voltage, the duty cycle increases to $100 \%$ which is the dropout condition. In the dropout condition, the PMOS switch is turned on continuously with the output voltage being equal to the input voltage minus the voltage drops across the internal P-channel MOSFETs and inductors.

## Low Supply Operation

The LTC3546 incorporates an undervoltage lockout circuit which shuts down the part when the input voltage drops below about 2.14 V to prevent unstable operation.

## APPLICATIONS InFORMATION

A general LTC3546 application circuit is shown in Figure 7. External component selection is driven by the load requirement, and begins with the selection of the inductors L1, and L 2 . Once L 1 and L 2 are chosen, $\mathrm{C}_{\mathrm{IN}}, \mathrm{C}_{\text {OUT1 }}$, and $\mathrm{C}_{\text {OUT2 }}$ can be selected.

## Operating Frequency

Selection of the operating frequency is a trade-off between efficiency and component size. High frequency operation allows the use of smaller inductor and capacitor values. Operation at lower frequencies improves efficiency by reducing internal gate charge losses but requires larger inductance values and/or capacitance to maintain low output ripple voltage.
The operating frequency, $f_{0}$, of the LTC3546 is determined by pulling the FREQ pin to $\mathrm{V}_{\mathrm{IN}^{\prime}}$, for 2.25 MHz operation, by connecting an external resistor from FREQ to ground, or by driving an external clock signal into SYNC/MODE.

When using an external resistor to set the oscillator frequency use the following equation:

$$
\mathrm{R}_{\mathrm{T}}=\frac{2.51 \bullet 10^{11}}{\mathrm{f}_{0}}(\Omega)-20 \mathrm{k} \Omega
$$

for $0.75 \mathrm{MHz} \leq \mathrm{f}_{0} \leq 4 \mathrm{MHz}$. Or use Figure 1 to select the value for $\mathrm{R}_{\mathrm{T}}$.
The maximum operating frequency is also constrained by the minimum on-time (typically 70ns) and duty cycle, especially when forced continuous mode is selected.

Assuming a worst-case minimum on-time of 150 ns , this can be calculated as:

$$
\mathrm{f}_{0(\mathrm{MAX})} \approx 6.67\left(\frac{\mathrm{~V}_{\text {OUT }}}{\mathrm{V}_{\text {IN(MAX })}}\right)(\mathrm{MHz})
$$

The minimum frequency is limited by leakage and noise coupling due to the large resistance of $\mathrm{R}_{\mathrm{T}}$.

## Inductor Selection

Although the inductor does not influence the operating frequency, the inductor value has a direct effect on ripple current. The inductor ripple current $\Delta I_{L}$ decreases with higher inductance and increases with higher $\mathrm{V}_{\text {IN }}$ or $\mathrm{V}_{\text {OUT }}$.

$$
\Delta \mathrm{I}_{\mathrm{L}}=\frac{\mathrm{V}_{\text {OUT }}}{f_{0} \bullet \mathrm{~L}}\left(1-\frac{\mathrm{V}_{0 \mathrm{OT}}}{\mathrm{~V}_{\mathrm{IN}}}\right)
$$

Accepting larger values of $\Delta \mathrm{L}_{\mathrm{L}}$ allows the use of low inductances, but results in higher output voltage ripple, greater core losses, and lower output current capability.

A reasonable starting point for setting ripple current is $\Delta \mathrm{L}_{\mathrm{L}}$ $=0.35 \mathrm{I}_{\mathrm{LOAD}(\mathrm{MAX})}$, where $\mathrm{I}_{\mathrm{LOAD}(\operatorname{MAX})}$ is the maximum output current. The largest ripple $\Delta \mathrm{L}_{\mathrm{L}}$ occurs at the maximum input voltage. To guarantee that the ripple current stays below a specified maximum, the inductor value should be chosen according to the following equation:

$$
\mathrm{L} \geq \frac{\mathrm{V}_{\text {OUT }}}{\mathrm{f}_{0} \cdot \Delta \mathrm{I}_{\mathrm{L}}}\left(1-\frac{\mathrm{V}_{\text {OUT }}}{\mathrm{V}_{\text {IN(MAX) }}}\right)
$$

Figure 1. Frequency vs $\mathbf{R}_{\mathbf{T}}$

## APPLICATIONS INFORMATION

## Burst Mode Operation Considerations

Thereare two factors that determine the load current at which the LTC3546 enters Burst Mode operation: the inductor value and the BMC pin voltage. The transition from low current operation begins when the peak inductor current falls below alevel set by the burstclamp. Lower inductorvalues result in higher ripple current which causes Burst Mode operation to occur at lowerload currents. Lower inductorvalues will also cause a dip in efficiency in the upper range of low current operation. Lower inductor values will also cause the burst frequency to increase in Burst Mode operation.

The burst clamp level can be set by the voltage on the BMC pin. If $B M C$ is tied to $V_{I N}$, an internally set level is used. A BMC pin voltage between 0 V and 0.6 V will set the burst clamp level (see charts OUT1 Minimum Peak Current vs $V_{\text {BMC1 }}$ and OUT2 Minimum Peak Current vs $\mathrm{V}_{\text {BMC2 }}$ in the Typical Performance Characteristics section). Generally, a higher clamp level results in improved light load efficiency and higher output voltage ripple, while a lower clamp level results in small output voltage ripple at the expense of efficiency. The BMC pin should be connected to ground when Burst Mode operation is not selected.

## Inductor Core Selection

Different core materials and shapes will change the size/current relationship of an inductor. Toroid or shielded pot cores in ferrite or permalloy materials are small and don't radiate much energy, but generally cost more than powdered iron core inductors with similar electrical characteristics. The choice of which style inductor to use often depends more on the price vs size requirements of any radiated field/EMI requirements than on what the LTC3546 requires to operate. Table 1 shows some typical surface mount inductors that work well in LTC3546 applications.

## Input Capacitor ( $\mathbf{C}_{\mathrm{IN}}$ ) Selection

In continuous mode, the input current of the converter can be approximated by the sum of two square waves with duty cycles of approximately $\mathrm{V}_{\text {OUT1 }} / \mathrm{V}_{\text {IN }}$ and $\mathrm{V}_{\text {OUT2 }} / V_{\text {IN }}$. To prevent large voltage transients, a low equivalent series resistance (ESR) input capacitor sized for the maximum RMS current must be used. Some capacitors have a derating spec for maximum RMS current. If the capacitor being used has this requirement it is necessary to calculate

Table 1.

| MANUFACTURER | PART NUMBER | VALUE $(\boldsymbol{\mu H})$ | MAX DC CURRENT (A) | DCR | DIMENSIONS $\mathbf{L} \times \mathbf{W} \times \mathbf{H}(\mathbf{m m})$ |

## APPLICATIONS INFORMATION

the maximum RMS current. The RMS current calculation is different if the part is used in-phase or out-of-phase.
For in-phase, there are two different equations:
$\mathrm{V}_{\text {OUT1 }}>\mathrm{V}_{\text {OUT2 }}$ :
$\mathrm{I}_{\mathrm{RMS}}=$
$\sqrt{2 \cdot \mid 1 \cdot 12 \cdot D 2(1-D 1)+12^{2}\left(D 2-D 2^{2}\right)+11^{2}\left(D 1-D 1^{2}\right)}$
$\mathrm{V}_{\text {OUT2 }}>\mathrm{V}_{\text {OUT1 }}:$
$\mathrm{I}_{\text {RMS }}=$
$\sqrt{2 \cdot|1 \cdot| 2 \cdot D 1(1-D 2)+12^{2}\left(D 2-D 2^{2}\right)+11^{2}\left(D 1-D 1^{2}\right)}$
Where:

$$
D 1=\frac{V_{\text {OUT1 }}}{V_{\text {IN }}} \text { and } D 2=\frac{V_{\text {OUT2 }}}{V_{\text {IN }}}
$$

When $\mathrm{D} 1=\mathrm{D} 2$, then the equation simplifies to:

$$
I_{\mathrm{RMS}}=(\mid 1+I 2) \sqrt{D(1-D)}
$$

or

$$
I_{\text {RMS }}=(11+I 2) \frac{\sqrt{V_{\text {OUT }}\left(V_{\text {IN }}-V_{\text {OUT }}\right)}}{V_{\text {IN }}}
$$

where the maximum average output currents 11 and 12 equals the peak current minus half the peak-to-peak ripple current:

$$
\begin{aligned}
& \mathrm{I}=\mathrm{I}_{\mathrm{LIM} 1}-\frac{\Delta \mathrm{I}_{\mathrm{L} 1}}{2} \\
& \mathrm{I} 2=\mathrm{I}_{\mathrm{LIM} 2}-\frac{\Delta \mathrm{L}_{\mathrm{L} 2}}{2}
\end{aligned}
$$

These formula have a maximum at $\mathrm{V}_{I N}=2 \mathrm{~V}_{\text {OUT }}$, where $I_{\text {RMS }}=(11+I 2) / 2$. This simple worst-case is commonly used to determine the worst-case $\mathrm{I}_{\text {RMS }}$.

For out-of-phase (PHASE pin is at ground), the ripple current can be lower than the in-phase.

In the out-of-phase case, the maximum $I_{\text {RMS }}$ does not occur when $\mathrm{V}_{\text {OUT1 }}=\mathrm{V}_{\text {OUT2 }}$. The maximum typically occurs
when $\mathrm{V}_{\text {OUT1 }}-\mathrm{V}_{\text {IN }} / 2=\mathrm{V}_{\text {OUT2 }}$ and when $\mathrm{V}_{\text {OUT2 }}-\mathrm{V}_{\text {IN }} / 2=$ $V_{\text {OUT1 }}$. As a good rule of thumb, the amount of worst-case ripple is about $75 \%$ of the worst-case ripple in the in-phase mode. Note, that when $\mathrm{V}_{\text {OUT1 }}=\mathrm{V}_{\text {OUT2 }}=\mathrm{V}_{\text {IN }} / 2$ and $\mathrm{I}_{1}=\mathrm{I}_{2}$, the ripple is at its minimum.
Note that capacitor manufacturer's ripple current ratings are often based on only 2000 hours lifetime. This makes it advisable to further derate the capacitor, or choose a capacitor rated at a higher temperature than required. Several capacitors may also be paralleled to meet the size or height requirements of the design. An additional $0.1 \mu \mathrm{~F}$ to $1 \mu \mathrm{~F}$ ceramic capacitor is also recommended on $V_{\text {IN }}$ for high frequency decoupling, when not using an all ceramic capacitor solution.

## Output Capacitor ( $C_{\text {OUT1 }}$ and $\mathrm{C}_{\text {OUT2 }}$ ) Selection

The selection of $\mathrm{C}_{\text {OUT1 } 1}$ and $\mathrm{C}_{\text {OUT2 } 2}$ is driven by the required ESR to minimize voltage ripple and load step transients. Typically, once the ESR requirement is satisfied, the capacitance is adequate for filtering. The output ripple ( $\Delta \mathrm{V}_{\text {OUT }}$ ) is determined by:

$$
\Delta \mathrm{V}_{\text {OUT }} \approx \Delta \mathrm{I}_{\mathrm{L}}\left(\mathrm{ESR}+\frac{1}{8 \bullet \mathrm{f}_{0} \bullet \mathrm{C}_{\text {OUT }}}\right)
$$

where $\mathrm{f}_{0}=$ operating frequency, $\mathrm{C}_{\text {OUT }}=$ output capacitance and $\Delta I_{L}=$ ripple current in the inductor. The output ripple is highest at maximum input voltage since $\Delta_{\mathrm{L}}$ increases with input voltage.

Once the ESR requirements for $\mathrm{C}_{\text {OUT }}$ have been met, the RMS current rating generally far exceeds the $I_{\text {RIPPLE (P-P) }}$ requirement, except for an all ceramic solution.

In surface mount applications, multiple capacitors may have to be paralleled to meet the capacitance, ESR or RMS current handling requirement of the application. Aluminum electrolytic, special polymer, ceramic and dry tantalum capacitors are all available in surface mount packages. The OS-CON semiconductor dielectric capacitor available from Sanyo has the lowest ESR(size) product of any aluminum electrolytic at a somewhat higher price. Special polymer capacitors, such as Sanyo POSCAP, offer very low ESR, but have a lower capacitance density than other types. Tantalum capacitors have the highest capacitance

## APPLICATIONS INFORMATION

density, but it has a larger ESR and it is critical that the capacitors are surge tested for use in switching power supplies. An excellent choice is the AVX TPS series of surface tantalums, available in case heights ranging from 2 mm to 4 mm . Aluminum electrolytic capacitors have a significantly larger ESR, and are often used in extremely cost-sensitive applications provided that consideration is given to ripple current ratings and long term reliability. Ceramic capacitors have the lowest ESR and cost but also have the lowest capacitance density, high voltage and temperature coefficient and exhibit audible piezoelectric effects. In addition, the high Q of ceramic capacitors along with trace inductance can lead to significant ringing. Other capacitor types include the Panasonic specialty polymer (SP) capacitors.

## Ceramic Input and Output Capacitors

Higher value, lower cost ceramic capacitors are now becoming available in smaller case sizes. Because the LTC3546 control loop does not depend on the output capacitor's ESR for stable operation, ceramic capacitors can be used freely to achieve very low output ripple and small circuit size. When choosing the input and output ceramic capacitors, choose the X5R or X7R dielectric formulations. These dielectrics have the best temperature and voltage characteristics of all the ceramics for a given value and size.

Great care must be taken when using only ceramic input and output capacitors. When a ceramic capacitor is used at the input and the power is being supplied through long wires, such as from a wall adapter, a load step at the output can induce ringing at the $\mathrm{V}_{\text {IN }}$ pin. At best, this ringing can couple to the output and be mistaken as loop instability. At worst, the ringing at the input can be large enough to disrupt circuit operation or damage the part.

Since the ESR of a ceramic capacitor is so low, the input and output capacitor must instead fulfill a charge storage requirement. During a load step, the output capacitor must instantaneously supply the current to support the load until the feedback loop raises the switch current enough
to support the load. The time required for the feedback loop to respond is dependent on the compensation components and the output capacitor size. Typically, 3 to 4 cycles are required to respond to a load step, but only in the first cycle does the output drop linearly. The output droop, $V_{\text {DROOp, }}$ is usually about 2 to 3 times the linear droop of the first cycle. Thus, a good place to start is with the output capacitor size of approximately:

$$
\mathrm{C}_{\text {OUT }} \approx 2.5 \frac{\Delta \mathrm{I}_{\text {OUT }}}{\mathrm{f}_{0} \mathrm{~V}_{\text {DROOP }}}
$$

More capacitance may be required depending on the duty cycle and load step requirements.

In most applications, the input capacitor is merely required to supply high frequency bypassing, since impedance to the supply is very low. A $10 \mu \mathrm{~F}$ ceramic capacitor is usually enough for these conditions.

## Setting the Output Voltage

The LTC3546 generates a 0.6 V reference voltage between the feedback pin, $\mathrm{V}_{\mathrm{FB} 1}$ and $\mathrm{V}_{\mathrm{FB} 2}$, and the signal ground. The output voltage is set by a resistive divider according to the following formula:

$$
\begin{aligned}
& V_{\text {OUT1 } 1} \approx 0.6 \mathrm{~V}\left(1+\frac{\mathrm{R} 1}{\mathrm{R} 2}\right) \\
& \mathrm{V}_{\text {OUT2 }} \approx 0.6 \mathrm{~V}\left(1+\frac{\mathrm{R} 3}{\mathrm{R} 4}\right)
\end{aligned}
$$

Resistor locations are shown in Figure 2.

Figure 2. Setting Output Voltages

## APPLICATIONS INFORMATION

Keeping the current small $(<20 \mu \mathrm{~A})$ in these resistors maximizes efficiency, but making the current too small may allow stray capacitance to cause noise problems and reduce the phase margin of the error amp loop.
To improve the frequency response, a feedforward capacitor $\mathrm{C}_{\text {FF }}$ may also be used. Typical values used here are 10 pf to 100pf. Great care should be taken to route the $\mathrm{V}_{\text {FB }}$ node away from noise sources, such as the inductor or an SW line.

## Shutdown, Soft-Start and Tracking Start-Up

The LTC3546 start-up works by comparing two inputs, an internal 1.2 ms linear soft-start ramp and the TRACK/SS pin. Whichever input is lower in voltage is the controlling voltage used for start-up. The internal start-up ramps to 0.6 V in 1.2 ms . If a slower start-up is desired, the TRACK/SS pin has a $1.15 \mu \mathrm{~A}$ pull up current so a start-up ramp rate can be programmed with an external capacitor, or a voltage divider from another signal can be applied to the TRACK/SS pin.
During start-up the controlling voltage must rise above 120 mV before the output will start switching.
When the RUN pin is low, both the internal 1.2 ms soft-start ramp and the TRACK/SS pin are pulled to ground. When the RUN pin is pulled high, both the internal soft-start ramp and the TRACK/SS pin are released. From the time when the RUN pin is asserted until the controlling voltage reaches 0.6 V , the regulator is in the start-up state. In this state, the error amplifier will compare the feedback signal at $\mathrm{V}_{\mathrm{FB}}$ to the controlling voltage (the lower of either the TRACK/SS voltage or the internal ramp voltage) and the regulator will force them to be equal. In this state, the mode of the regulator is forced to pulse skipping. The regulator will continue in this manner until the voltage on the controlling voltage rises above 0.6 V . Once the controlling ramp signal is above 0.6 V the error amplifier uses the internal 0.6 V reference and the operational mode will switch to the mode set by the SYNC/MODE pin.

If the TRACK/SS pin is ramped down after start-up, the error amplifier will compare the feedback signal at $\mathrm{V}_{\mathrm{FB}}$ to the voltage on the TRACK/SS pin once the TRACK/SS voltage drops $6 \%$ below the internal reference voltage of $0.6 \mathrm{~V}(0.564 \mathrm{~V})$. The regulator will try to force the $\mathrm{V}_{\mathrm{FB}}$ Voltage
to equal the TRACK/SS voltage if there is sufficient load current to pull the output low at this rate, otherwise the output will ramp down at the discharge rate of the output capacitor. Once the TRACK/SS voltage drops below about 100 mV all switching functions cease and the regulator is forced back into pulse-skipping mode. The operational mode while TRACK/SS is ramping down is set by the MODE/SYNC pin.

To use the internal 1.2 ms linear soft-start controlling voltage leave the TRACK/SS pin floating. By floating the TRACK/SS pin the internal $1.15 \mu \mathrm{~A}$ pull up current will pull the TRACK/SS pin up faster than the internal 1.2 ms ramp. Care must be taken to insure the TRACK/SS ramp up time (from 0 V to 0.6 V ) is much shorter than the internal 1.2 ms ramp time. Parasitic capacitance on this pin should be much smaller than:

$$
\mathrm{C}_{\text {PARASITICTRACK/SS }} \ll \frac{1.15 \mu \mathrm{~A} \bullet 1.2 \mathrm{~ms}}{0.6 \mathrm{~V}}
$$

or

## CPARASITICTRACK/SS < 2.3nF

An externally controlled soft-start ramp is obtained when an external capacitor is connected from the TRACK/SS pin to ground and its ramp rate is slower than the internal soft-start ramp. In this configuration, soft-start times longer than 1.2 ms can be achieved. When RUN is pulled high, the internal $1.15 \mu \mathrm{~A}$ current source charges the external capacitor linearly from 0 V . While the TRACK/SS pin is below 0.6 V the error amplifier forces the regulator to drive the $V_{F B}$ pin to the voltage on the TRACK/SS pin. Once the $V_{F B}$ pin reaches 0.6 V the regulator switches to the internal 0.6 V reference. The ramp-up time for the output is calculated as:

$$
\mathrm{t}_{\text {RAMP }}=\frac{\mathrm{C}_{\text {TRACK/SS }} \bullet 0.6 \mathrm{~V}}{1.15 \mu \mathrm{~A}}
$$

For this equation to be valid, the ramp time must be greater than 1.2 ms thus:

$$
\mathrm{C}_{\text {TRACK/SS }} \geq \frac{1.15 \mu \mathrm{~A} \cdot 1.2 \mathrm{~ms}}{0.6 \mathrm{~V}}
$$

or
$\mathrm{C}_{\text {TRACK/SS }} \geq 2.3 \mathrm{nF}$

## APPLICATIONS INFORMATION

The LTC3546 can also track an external voltage during startup by using an external voltage divider to the TRACK/SS pin, and also insuring that the ramp rate on the TRACK/SS pin is slower than the internal 1.2 ms ramp rate.

As indicated in Figure 3, a resistor divider from an external voltage can be connected to the TRACK/SS pin to allow the start-up of $V_{\text {OUT }}$ to ratiometrically track an external voltage $V_{x}$.

$$
\begin{aligned}
& \text { For } V_{\text {TRACKSS }}<0.6 \mathrm{~V} \\
& \qquad V_{\text {OUT }}=V_{X} \bullet \frac{R 2 X}{R 1 X+R 2 X} \bullet \frac{R 1+R 2}{R 2}
\end{aligned}
$$

Figure 3. Tracking External Voltages
Coincident tracking is where $\mathrm{V}_{\text {OUT }}=\mathrm{V}_{\mathrm{X}}$ during startup. To implement coincident tracking R1X in Figure 3 is set to the same value as R1 and R2X to the value of R2. Coincident tracking is illustrated in Figure 4. The voltage at TRACK/SS when $V_{X}$ is at its final value should be $\geq 0.8 \mathrm{~V}$ (sufficient margin above the 0.6 V reference voltage).
Ratiometric tracking is where $\mathrm{V}_{\text {OUT }} \neq \mathrm{V}_{\mathrm{X}}$ during startup but rather, it is set to some fractional value of $\mathrm{V}_{\mathrm{X}}$. To implement ratiometric tracking (as illustrated in Figure 5), set R1X in Figure 3 to the same value as R1 and R2X to the value of $R 2+\Delta R$. The $\Delta R$ added to $R 2$ should be sufficient so that the TRACK/SS voltage is $\geq 0.8 \mathrm{~V}$ when $V_{X}$ is at its final value.
The internal $1.15 \mu A$ pull up current on TRACK/SS can cause a tracking error at $\mathrm{V}_{\text {OUT }}$ when using a resistor divider on TRACK/SS. For example, if a 59 k resistor is chosen for R2X, the R2X current will be about $10 \mu \mathrm{~A}(0.6 \mathrm{~V} / 59 \mathrm{k})$. In this case, the $1.15 \mu \mathrm{~A}$ internal current source will cause about $11 \%(1.15 \mu \mathrm{~A} / 10 \mu \mathrm{~A})$ tracking error, which is about 66 mV referred to $\mathrm{V}_{\mathrm{FB}}$. This is acceptable for most applications. If a better tracking accuracy is required, the value of R2X can be reduced or the $1.15 \mu \mathrm{~A}$ current can be taken into account in the equations.

Figure 4. Coincident Tracking

Figure 5. Ratiometric Tracking

Table 2 summarizes the different states in which the TRACK/SS can be used.

Table 2. The States of the TRACK/SS Pin

| TRACK/SS PIN | RESULT |
| :--- | :--- |
| Capacitor to Ground | External Soft-Start |
| Floating | Internal Soft-Start |
| Resistor Divider | $V_{\text {OUT Tracking an External Voltage } \mathrm{V}_{\mathrm{X}}}$ |

Regardless of the mode implemented, the TRACK/SS pin should never be pulled high externally as this will result in excessive current during shutdown.

The LTC3546 can smoothly handle starting up into a prebiased output. The tracking function will pick up from the pre-biased voltage and ramp the output up from there.

## Mode Selection

The SYNC/MODE pin is a multipurpose pin which provides mode selection and frequency synchronization. Connecting this pin to $\mathrm{V}_{\text {IN }}$ enables Burst Mode operation for both reg-

## APPLICATIONS INFORMATION

ulators. This mode provides the best low current efficiency at the cost of a higher output voltage ripple. When SYNC/ MODE is connected to ground, pulse-skipping operation is selected for both regulators. This mode provides a lower output voltage and current ripple at the cost of low current efficiency. Applying $\mathrm{V}_{\mathbf{I N}} / 2$ results in forced continuous mode for both regulators. This mode creates a fixed output ripple and is capable of sinking some current (about $1 / 2 \cdot \Delta \mathrm{I}_{\mathrm{L}}$ ). Since the switching noise is constant in this mode, it is also the easiestto filter out. During initial start-up, pulse-skipping mode is forced until the PGOOD pin goes high.

The LTC3546 can also be synchronized to an external clock signal by the SYNC/MODE pin. An internal phase locked loop locks to the incoming signal to provide for $180^{\circ}$ out-of-phase operation as well as correct slope compensation. With external synchronization the FREQ pin is used for externally compensating the internal phase locked loop. Typical values used for compensation are 200k and 100pf, as shown in Figure 6. During synchronization, the regulator operating mode is forced to pulse skipping. The $P$-channel switch turn on is synchronized to the rising edge of the external clock.
When using an external clock, with the PHASE pin low, the switching of the two channels occur $180^{\circ}$ out-of-phase.

Figure 6. PLL Compensation

## Checking Transient Response

The $I_{\text {TH }}$ pin compensation allows the transient response to be optimized for a wide range of loads and output capacitors. The availability of the $\mathrm{I}_{\text {TH }}$ pin not only allows optimization of the control loop behavior but also provides a DC-coupled and AC filtered closed loop response test point. The DC step, rise time and settling at this test point truly reflects the closed loop response. Assuming a predominantly second order system, phase margin and/or damping factor can be estimated using the percentage of overshoot seen at this pin. The bandwidth can also be
estimated using the percentage of overshoot seen at this pin, or by examining the rise time at this pin.
The $I_{T H}$ external components shown in the Figure 9 circuit will provide an adequate starting point for most applications. The series R-C filter sets the dominant pole-zero loop compensation. The values can be modified slightly (from 0.5 to 2 times their suggested values) to optimize transient response once the final PC layout is done and the particular output capacitor type and value have been determined. The output capacitors need to be selected because of various types and values determine the loop feedback factor gain and phase. An output current pulse of $20 \%$ to $100 \%$ of full load current having a rise time of $1 \mu \mathrm{~s}$ to $10 \mu \mathrm{~s}$ will produce output voltage and $\mathrm{I}_{\mathrm{TH}}$ pin waveforms that will give a sense of overall loop stability without breaking the feedback loop.

Switching regulators take several cycles to respond to a step in load current. When a load step occurs, Vout immediately shifts by an amount equal to $\Delta l_{\text {LOAD }} \bullet E S R$, where ESR is the effective series resistance of $\mathrm{C}_{\text {OUT }}$. The $\Delta_{\text {LOAD }}$ also begins to charge or discharge COUT generating a feedback error signal used by the regulator to return $V_{\text {Out }}$ to its steady-state value. During this recovery time, $V_{\text {OUT }}$ can be monitored for overshoot or ringing that would indicate a stability problem.

The initial output voltage step may not be within the bandwidth of the feedback loop, so the standard second order overshoot/DC ratio cannot be used to determine phase margin. The gain of the loop increases with $\mathrm{R}_{\mathrm{ITH}}$ and the bandwidth of the loop increases with decreasing $\mathrm{C}_{\text {ITH. }}$. If $\mathrm{R}_{\text {ITH }}$ is increased by the same factor that $\mathrm{C}_{I T H}$ is decreased, the zero frequency will be kept the same, thereby keeping the phase the same in the most critical frequency range of the feedback loop. In addition, feedforward capacitors, $\mathrm{C}_{\mathrm{FF} 1}$ and $\mathrm{C}_{\text {FF2 }}$, can be added to improve the high frequency response, as shown in Figure 9. Capacitor $\mathrm{C}_{\mathrm{FF} 1}$ provides phase lead by creating a high frequency zero with R1 which improves the phase margin for the 1A SW1 channel. Capacitor $\mathrm{C}_{\text {FF2 }}$ provides phase lead by creating a high frequency zero with R3 which improves the phase margin for the 3A SW1D/SW2 channel.

The outputvoltage settling behavior is related to the stability of the closed-loop system and will demonstrate the actual

## APPLICATIONS INFORMATION

overall supply performance. For a detailed explanation of optimizing the compensation components, including a review of control loop theory, refer to Linear Technology Application Note 76.

Although a buck regulator is capable of providing the full output current in dropout, it should be noted that as the inputvoltage $\mathrm{V}_{\text {IN }}$ drops toward $\mathrm{V}_{\text {OUT }}$, the load step capability does decrease due to the decreasing voltage across the inductor. Applications that require large load step capability near dropout should use a different topology such as SEPIC, Zeta, or single inductor, positive buck boost.

In some applications, a more severe transient can be caused by switching in loads with large ( $>1 \mu \mathrm{~F}$ ) input capacitors. The discharged input capacitors are effectively put in parallel with $\mathrm{C}_{\text {OUT }}$, causing a rapid drop in $\mathrm{V}_{\text {OUT }}$. No regulator can deliver enough current to prevent this problem, if the switch connecting the load has low resistance and is driven quickly. The solution is to limit the turn-on speed of the load switch driver. A hot swap controller is designed specifically for this purpose and usually incorporates current limiting, short-circuit protection, and soft starting.

## Efficiency Considerations

The percent efficiency of a switching regulator is equal to the output power divided by the input power times 100. It is often useful to analyze individual losses to determine what is limiting the efficiency and which change would produce the most improvement. Percent efficiency can be expressed as:

```
\%Efficiency \(=100 \%-(P 1+P 2+\) P3 \(+\ldots)\)
```

where P1, P2, etc. are the individual losses as a percentage of input power.
Although all dissipative elements in the circuit produce losses, four main sources usually account for most of the losses in LTC3546 circuits: 1) LTC3546 Vin current, 2) switching losses, 3) $I^{2} R$ losses, 4) other losses.

1. The $\mathrm{V}_{\text {IN }}$ current is the DC supply current given in the electrical characteristics which excludes MOSFET driver and control currents. $\mathrm{V}_{\text {IN }}$ current results in a small $(<0.1 \%)$ loss that increases with $\mathrm{V}_{\text {IN }}$, even at no-load.
2. The switching current is the sum of the MOSFET driver and control currents. The MOSFET driver current results from switching the gate capacitance of the power MOSFETs. Each time a MOSFET gate is switched from Iow to high to low again, a packet of charge moves from $\mathrm{V}_{\text {IN }}$ to ground. The resulting charge over the switching period is a current out of $\mathrm{V}_{\text {IN }}$ that is typically much larger than the DC bias current. The gate charge losses are proportional to $\mathrm{V}_{\text {IN }}$ and thus their effects will be more pronounced at higher supply voltages.
3. $I^{2} R$ losses are calculated from the $D C$ resistances of the internal switches, $\mathrm{R}_{\mathrm{SW}}$, and the external inductor, $\mathrm{R}_{\mathrm{L}}$. In continuous mode, the average output current flowing through inductor $L$ is "chopped" between the internal top and bottom switches. Thus, the series resistance looking into the SW pin is a function of both top and bottom MOSFET $\mathrm{R}_{\mathrm{DS}(\mathrm{ON})}$ and the duty cycle (DC) as follows:

$$
R_{S W}=\left(R_{D S(O N)} T O P\right)(D C)+\left(R_{D S(O N)} B O T\right)(1-D C)
$$

The R $\mathrm{RS}_{(0 \mathrm{ON})}$ for both the top and bottom MOSFETs can be obtained from the Typical Performance Characteristics curves. Thus, to obtain $I^{2} R$ losses:

$$
I^{2} R \text { losses }=I_{0 U T}^{2}\left(R_{S W}+R_{L}\right)
$$

Where $R_{L}$ is the resistance of the inductor.
4. Other hidden losses such as copper trace and internal battery resistances can account for additional efficiency degradations in portable systems. It is very important to include these "system" level losses in the design of a system. The internal battery and fuse resistance losses can be minimized by making sure that $\mathrm{C}_{\mathrm{IN}}$ has adequate charge storage and very low ESR at the switching frequency. Other losses including diode conduction losses during dead-time and inductor core losses generally account for less than $2 \%$ total additional loss.

## Thermal Considerations

The LTC3546 requires the backplane metal (Pin 29) to be well soldered to the PC board. This gives the UFD package exceptional thermal properties, compared to similar packages of this size, making it difficult in normal opera-

## APPLICATIONS INFORMATION

tion to exceed the maximum junction temperature of the part. In a majority of applications, the LTC3546 does not dissipate much heat due to its high efficiency. However, in applications where the LTC3546 is running at high ambient temperature with low supply voltage and high duty cycles, such as in dropout, the heat dissipated may exceed the maximum junction temperature of the part. If the junction temperature reaches approximately $150^{\circ} \mathrm{C}$, both switches in both regulators will be turned off and the SW nodes will become high impedance.

To avoid the LTC3546 from exceeding the maximum junction temperature, the user will need to do some thermal analysis. The goal of the thermal analysis is to determine whether the power dissipated exceeds the maximum junction temperature of the part. The temperature rise is given by:

$$
T_{\text {RISE }}=P_{D} \bullet \theta_{J A}
$$

where $\mathrm{P}_{\mathrm{D}}$ is the power dissipated by the regulator and $\theta_{\mathrm{JA}}$ is the thermal resistance from the junction of the die to the ambient temperature.

The junction temperature, $T_{J}$, is given by:

$$
T_{J}=T_{\text {RISE }}+T_{\text {AMBIENT }}
$$

As an example, consider the case when the LTC3546 is in dropout in both regulators at an input voltage of 3.3 V with load currents of 3A (SW1D externally connected to SW2) and 1A. From the Typical Performance Characteristics graph of Switch Resistance, the $R_{D S(O N)}$ resistance of the 3A P-channel switch parallel combination of SW2 and SW1D is $0.06 \Omega$ and the $R_{D S(0 N)}$ of the $1 \mathrm{~A} \mathrm{P-channel}$ switch is $0.18 \Omega$. The power dissipated by the part is:

$$
\begin{aligned}
& P_{D}=11^{2} R_{D S(O N) 1}+12^{2} R_{D S(O N) 2} \\
& P_{D}=3^{2} \cdot 0.064+1^{2} \cdot 0.19 \\
& P_{D}=0.77 W
\end{aligned}
$$

The UFD package junction-to-ambient thermal resistance, $\theta_{\mathrm{JA}}$, is about $34^{\circ} \mathrm{C} / \mathrm{W}$. Therefore, the junction temperature of the regulator operating in a $85^{\circ} \mathrm{C}$ ambient temperature is approximately:

$$
\begin{aligned}
& \mathrm{T}_{\mathrm{J}}=0.77 \cdot 34+85 \\
& \mathrm{~T}_{\mathrm{J}}=111.2^{\circ} \mathrm{C}
\end{aligned}
$$

This junction temperature is obtained from an $\mathrm{R}_{\mathrm{DS}(\mathrm{ON})}$ at $25^{\circ} \mathrm{C}$. At $125^{\circ} \mathrm{C}$ the $\mathrm{R}_{\mathrm{DS}(0 \mathrm{ON})}$ increases by about $30 \%$. This will put the junction temperature at $122^{\circ} \mathrm{C}$. If the supply is lower, like 2.25 V , the $\mathrm{R}_{\mathrm{DS}(0 \mathrm{O})}$ is higher still. Special care needs to be taken if the part is expected to be operating in dropout so that the maximum junction temperature of $125^{\circ} \mathrm{C}$ is not exceeded.

## Design Example

As a design example, consider using the LTC3546 in a portable application with a Li-Ion battery. The battery provides a $\mathrm{V}_{\text {IN }}=2.25 \mathrm{~V}$ to 4.2 V . One output requires 1.8 V at 2.5 A in active mode, and 1 mA in standby mode. The other output requires 1.2 V at 800 mA in active mode, and $500 \mu \mathrm{~A}$ in stand-by mode. Since both loads still need power in stand-by, Burst Mode operation is selected for good low load efficiency.

First, determine what frequency should be used. Higher frequency results in a lower inductor value for a given $\Delta I_{L}$ ( $\Delta \mathrm{I}_{\mathrm{L}}$ is estimated as $0.35 \mathrm{I}_{\mathrm{LOAD}(\mathrm{MAX})}$ ). Reasonable values for wire wound surface mount inductors are in the $1 \mu \mathrm{H}$ and up. Look at the different frequencies with the $\Delta \mathrm{I}_{\mathrm{L}}=$ $0.35 \mathrm{~L}_{\text {LOAD (MAX) }}$.

| CONVERTER OUTPUT | $\mathbf{I}_{\text {LOAD(MAX) }}$ | $\Delta \mathbf{l}_{\mathbf{L}}$ |
| :---: | :---: | :---: |
| SW2/SW1D, 1.2 V | 2.5 A | 875 mA |
| SW1, 1.8 V | 800 mA | 280 mA |

Using the 1.5MHz frequency setting (FREQ=143kto GNDA) we get the following equations for L 1 and L 2 .

$$
\begin{aligned}
& \mathrm{L} 1=\frac{1.2 \mathrm{~V}}{1.5 \mathrm{MHz} \cdot 280 \mathrm{~mA}} \cdot\left(1-\frac{1.2 \mathrm{~V}}{4.2 \mathrm{~V}}\right)=2 \mu \mathrm{H} \\
& \mathrm{~L} 2=\frac{1.8 \mathrm{~V}}{1.5 \mathrm{MHz} \cdot 875 \mathrm{~mA}} \cdot\left(1-\frac{1.8 \mathrm{~V}}{4.2 \mathrm{~V}}\right)=0.78 \mu \mathrm{H}
\end{aligned}
$$

Use $1 \mu \mathrm{H}$ and $2.2 \mu \mathrm{H}$.
Cout selection is typically based on load step rather than the ripple requirements. The minimum required capacitance will increase with a decrease in compensation loop bandwidth and/or increases in maximum load step or output voltage tolerance. A good starting point is about $22 \mu \mathrm{~F}$ per ampere of output current for a nominal

## APPLICATIONS INFORMATION

operating frequency of 1.5 MHz and assumes roughly a $300 \mathrm{~mA} / \mathrm{A}$ load step.

$$
\begin{aligned}
& \mathrm{C}_{\text {OUT } 1}=\frac{22 \mu \mathrm{~F}}{\mathrm{~A}} \cdot 0.8 \mathrm{~A} \cdot \frac{280 \mathrm{~mA}}{\frac{300 \mathrm{~mA}}{\mathrm{~A}} \cdot 0.8 \mathrm{~A}}=20.5 \mu \mathrm{~F} \\
& \mathrm{C}_{\text {OUT } 1}=\frac{22 \mu \mathrm{~F}}{\mathrm{~A}} \cdot 2.5 \mathrm{~A} \cdot \frac{875 \mathrm{~mA}}{\frac{300 \mathrm{~mA}}{\mathrm{~A}} \cdot 2.5 \mathrm{~A}}=64.2 \mu \mathrm{~F}
\end{aligned}
$$

The closest values are $22 \mu \mathrm{~F}$ and $68 \mu \mathrm{~F}$.
The output voltages can now be programmed by choosing the values of R1, R2, R3, and R4. To maintain high efficiency, the current in these resistors should be kept small. Choosing $2 \mu \mathrm{~A}$ with the 0.6 V feedback voltages makes R2 and R4 equal to 300k. A close standard 1\% resistor is 301 k . This then makes $\mathrm{R} 1=300 \mathrm{k}$. A close standard $1 \%$ is 301 k . R3 then equals 600k. A close $1 \%$ resistor is 604k.

The compensation should be optimized for these components by examining the load step response but a good place to start for the LTC3546 is with a $13 \mathrm{k} \Omega$ and 1000 pF filter on both $I_{T H 1}$ and $I_{T H 2}$. The output capacitor may need to be increased depending on the actual transient during a load step.

The PGOOD pin is a common drain output and requires a pull-up resistor. A 100k resistor is used for adequate speed. Figure 9 shows a complete schematic for this design.

## Board Layout Considerations

When laying out the printed circuit board, the following checklist should be used to ensure proper operation of the LTC3546. These items are also illustrated graphically in the layout diagram of Figure 7. Check the following in your layout.

1. Make sure SW1, SW2A, SW2B and SW1D are connected on the PC board through a wide piece of copper.
2. All, or part, of $\mathrm{C}_{\mathrm{IN}}$ should connect from Pin 9 to Pin 14 on the same side of the PC board as the chip and as close to the chip as possible, where the SW traces will go directly under the capacitor. $\mathrm{C}_{\mathrm{IN}}$ provides the AC current to the internal power MOSFETs and their drivers.
3. Are the respective $\mathrm{C}_{0 \mathrm{UT}}$, L closely connected? The (-) plate of COUT1 returns current to PGND1, and the (-) plate of Cout2 returns current to the PGND2. The (-) plate of $\mathrm{C}_{\mathrm{IN}}$ should also return current to PGND1 and PGND2.
4. The resistor divider, R1 and R2, must be connected between the $(+)$ plate of $\mathrm{C}_{0 U T 1}$ and a ground line terminated near GNDA. The resistor divider R3 and R4, must be connected between the ( + ) plate of $\mathrm{C}_{\text {OUT2 } 2}$ and the ground connection terminated to the GNDA pin. The feedback signals $\mathrm{V}_{\text {FB1 }}$ and $\mathrm{V}_{\text {FB2 }}$ should be routed away from noise components and traces, such as the SW lines, and its trace should be minimized.
5. When using the RFREQ resistor, the ground connection of the resistor should be terminated to the GNDA pin. When using the internal PLL, the ground connection of the R-C compensation network should be terminated to the GNDA pin.
6. Keep sensitive components away from the SW pins. The input capacitor $\mathrm{C}_{\mathrm{IN}^{\prime}}$, the compensation capacitors $\mathrm{C}_{\text {FF1 }}, \mathrm{C}_{\text {FF2 }}, \mathrm{C}_{\text {ITH1 }}$, and $\mathrm{C}_{\text {ITH2 }}$ and all resistors R1, R2, R3, R4, R $\mathrm{R}_{\text {TH1 }}$ and $\mathrm{RITH}_{\mathrm{I} 2}$ should be routed away from the SW traces and the inductors L1 and L2.
7. A ground plane is preferred, but if not available, keep the signal and power grounds segregated with small signal components returning to the SGND pin at one point which is then connected to the PGND1/PGND2/ PGND1D/GNDD pins.
8. Flood all unused areas on all layers with copper. Flooding with copper will reduce the temperature rise of power components. These copper areas should be connected to the Exposed Pad (Pin 29).
