The following figure provides an ordering number example for the MC9S12H-Family devices.

**Figure 0-1 Order Partnumber Example**

The following items should be considered when using a derivative (**Table 0-1**):

- **Registers**
  - Do not write or read CAN0 registers (after reset: address range \$0140 - \$017F), if using a derivative without CAN0.
  - Do not write or read CAN1 registers (after reset: address range \$0180 - \$01BF), if using a derivative without CAN1.
  - Do not write or read CAN4 registers (after reset: address range \$0280 - \$02BF), if using a derivative without CAN4.
  - Do not write or read BDLC registers (after reset: address range \$00E8 - \$00EF), if using a derivative without BDLC.
- **Interrupts**
  - Fill the four CAN0 interrupt vectors (\$FFB0 - \$FFB7) according to your coding policies for unused interrupts, if using a derivative without CAN0.
  - Fill the four CAN1 interrupt vectors (\$FFA8 - \$FFAF) according to your coding policies for unused interrupts, if using a derivative without CAN1.
  - Fill the four CAN4 interrupt vectors (\$FF90 - \$FF97) according to your coding policies for unused interrupts, if using a derivative without CAN4.
  - Fill the BDLC interrupt vector (\$FFC2, \$FFC3) according to your coding policies for unused interrupts, if using a derivative without BDLC.
- **Ports**
  - The CAN0 pin functionality (TXCAN0, RXCAN0) is not available on port PJ7, PJ6, PM5, PM4, PM3, PM2, PM1 and PM0, if using a derivative without CAN0.
  - The CAN1 pin functionality (TXCAN1, RXCAN1) is not available on port PM3 and PM2, if using a derivative without CAN1.
  - The CAN4 pin functionality (TXCAN4, RXCAN4) is not available on port PJ7, PJ6, PM5, PM7, PM6, PM5 and PM4, if using a derivative without CAN0.
  - The BDLC pin functionality (TXB, RXB) is not available on port PM1 and PM0, if using a derivative without BDLC.
  - Do not write MODRR1 and MODRR0 bits of Module Routing Register (PIM\_9DP256 Block Guide), if using a derivative without CAN0.
  - Do not write MODRR3 and MODRR2 bits of Module Routing Register (PIM\_9DP256 Block Guide), if using a derivative without CAN4.

# Section 1 IntroductionMC9S12DT256

## 1.1 Overview

The MC9S12DT256 microcontroller unit (MCU) is a 16-bit device composed of standard on-chip peripherals including a 16-bit central processing unit (HCS12 CPU), 256K bytes of Flash EEPROM, 12K bytes of RAM, 4K bytes of EEPROM, two asynchronous serial communications interfaces (SCI), three serial peripheral interfaces (SPI), an 8-channel IC/OC enhanced capture timer, two 8-channel, 10-bit analog-to-digital converters (ADC), an 8-channel pulse-width modulator (PWM), a digital Byte Data Link Controller (BDLC), 29 discrete digital I/O channels (Port A, Port B, Port K and Port E), 20 discrete digital I/O lines with interrupt and wakeup capability, three CAN 2.0 A, B software compatible modules (MSCAN12), and an Inter-IC Bus. The MC9S12DT256 has full 16-bit data paths throughout. However, the external bus can operate in an 8-bit narrow mode so single 8-bit wide memory can be interfaced for lower cost systems. The inclusion of a PLL circuit allows power consumption and performance to be adjusted to suit operational requirements.

## 2.3 Detailed Signal Descriptions

### 2.3.1 EXTAL, XTAL — Oscillator Pins

EXTAL and XTAL are the crystal driver and external clock pins. On reset all the device clocks are derived from the EXTAL input frequency. XTAL is the crystal output.

### 2.3.2 RESET — External Reset Pin

An active low bidirectional control signal, it acts as an input to initialize the MCU to a known start-up state, and an output when an internal MCU function causes a reset.

### 2.3.3 TEST — Test Pin

This input only pin is reserved for test.

**NOTE:** The TEST pin must be tied to VSS in all applications.

### 2.3.4 VREGEN — Voltage Regulator Enable Pin

This input only pin enables or disables the on-chip voltage regulator.

### 2.3.5 XFC — PLL Loop Filter Pin

PLL loop filter. Please ask your Motorola representative for the interactive application note to compute PLL loop filter elements. Any current leakage on this pin must be avoided.

Figure 2-3 PLL Loop Filter Connections

### 2.3.6 BKGD / $\overline{\text{TAGHI}}$ / MODC — Background Debug, Tag High, and Mode Pin

The BKGD/ $\overline{\text{TAGHI}}$ /MODC pin is used as a pseudo-open-drain pin for the background debug communication. In MCU expanded modes of operation when instruction tagging is on, an input low on this pin during the falling edge of E-clock tags the high half of the instruction word being read into the instruction queue. It is used as a MCU operating mode select pin during reset. The state of this pin is latched to the MODC bit at the rising edge of  $\overline{\text{RESET}}$ . This pin has a permanently enabled pull-up device.

### 2.3.7 PAD15 / AN15 / ETRIG1 — Port AD Input Pin of ATD1

PAD15 is a general purpose input pin and analog input AN7 of the analog to digital converter ATD1. It can act as an external trigger input for the ATD1.

### 2.3.12 PB[7:0] / ADDR[7:0] / DATA[7:0] — Port B I/O Pins

PB7-PB0 are general purpose input or output pins. In MCU expanded modes of operation, these pins are used for the multiplexed external address and data bus.

### 2.3.13 PE7 / NOACC / $\overline{\text{XCLKS}}$ — Port E I/O Pin 7

PE7 is a general purpose input or output pin. During MCU expanded modes of operation, the NOACC signal, when enabled, is used to indicate that the current bus cycle is an unused or “free” cycle. This signal will assert when the CPU is not using the bus. The  $\overline{\text{XCLKS}}$  is an input signal which controls whether a crystal in combination with the internal Colpitts (low power) oscillator is used or whether Pierce oscillator/external clock circuitry is used. The state of this pin is latched at the rising edge of  $\overline{\text{RESET}}$ . If the input is a logic low the EXTAL pin is configured for an external clock drive or a Pierce Oscillator. If input is a logic high a Colpitts oscillator circuit is configured on EXTAL and XTAL. Since this pin is an input with a pull-up device during reset, if the pin is left floating, the default configuration is a Colpitts oscillator circuit on EXTAL and XTAL.

**Figure 2-4 Colpitts Oscillator Connections (PE7=1)**

- \* Due to the nature of a translated ground Colpitts oscillator a DC voltage bias is applied to the crystal  
 .Please contact the crystal manufacturer for crystal DC

**Figure 2-5 Pierce Oscillator Connections (PE7=0)**

- \* R<sub>s</sub> can be zero (shorted) when use with higher frequency crystals.  
 Refer to manufacturer's data.

Figure 2-6 External Clock Connections (PE7=0)

### 2.3.14 PE6 / MODB / IPIPE1 — Port E I/O Pin 6

PE6 is a general purpose input or output pin. It is used as a MCU operating mode select pin during reset. The state of this pin is latched to the MODB bit at the rising edge of  $\overline{\text{RESET}}$ . This pin is shared with the instruction queue tracking signal IPIPE1. This pin is an input with a pull-down device which is only active when  $\overline{\text{RESET}}$  is low.

### 2.3.15 PE5 / MODA / IPIPE0 — Port E I/O Pin 5

PE5 is a general purpose input or output pin. It is used as a MCU operating mode select pin during reset. The state of this pin is latched to the MODA bit at the rising edge of  $\overline{\text{RESET}}$ . This pin is shared with the instruction queue tracking signal IPIPE0. This pin is an input with a pull-down device which is only active when  $\overline{\text{RESET}}$  is low.

### 2.3.16 PE4 / ECLK — Port E I/O Pin 4

PE4 is a general purpose input or output pin. It can be configured to drive the internal bus clock ECLK. ECLK can be used as a timing reference.

### 2.3.17 PE3 / $\overline{\text{LSTRB}}$ / $\overline{\text{TAGLO}}$ — Port E I/O Pin 3

PE3 is a general purpose input or output pin. In MCU expanded modes of operation,  $\overline{\text{LSTRB}}$  can be used for the low-byte strobe function to indicate the type of bus access and when instruction tagging is on,  $\overline{\text{TAGLO}}$  is used to tag the low half of the instruction word being read into the instruction queue.

### 2.3.18 PE2 / $\overline{R\overline{W}}$ — Port E I/O Pin 2

PE2 is a general purpose input or output pin. In MCU expanded modes of operations, this pin drives the read/write output signal for the external bus. It indicates the direction of data on the external bus.

### 2.3.19 PE1 / $\overline{IRQ}$ — Port E Input Pin 1

PE1 is a general purpose input pin and the maskable interrupt request input that provides a means of applying asynchronous interrupt requests. This will wake up the MCU from STOP or WAIT mode.

## 2.4 Power Supply Pins

MC9S12DT256 power and ground pins are described below.

**NOTE:** *All VSS pins must be connected together in the application.*

### 2.4.1 VDDX,VSSX — Power & Ground Pins for I/O Drivers

External power and ground for I/O drivers. Because fast signal transitions place high, short-duration current demands on the power supply, use bypass capacitors with high-frequency characteristics and place them as close to the MCU as possible. Bypass requirements depend on how heavily the MCU pins are loaded.

### 2.4.2 VDDR, VSSR — Power & Ground Pins for I/O Drivers & for Internal Voltage Regulator

External power and ground for I/O drivers and input to the internal voltage regulator. Because fast signal transitions place high, short-duration current demands on the power supply, use bypass capacitors with high-frequency characteristics and place them as close to the MCU as possible. Bypass requirements depend on how heavily the MCU pins are loaded.

### 2.4.3 VDD1, VDD2, VSS1, VSS2 — Core Power Pins

Power is supplied to the MCU through VDD and VSS. Because fast signal transitions place high, short-duration current demands on the power supply, use bypass capacitors with high-frequency characteristics and place them as close to the MCU as possible. This 2.5V supply is derived from the internal voltage regulator. There is no static load on those pins allowed. The internal voltage regulator is turned off, if VREGEN is tied to ground.

**NOTE:** *No load allowed except for bypass capacitors.*

### 2.4.4 VDDA, VSSA — Power Supply Pins for ATD and VREG

VDDA, VSSA are the power supply and ground input pins for the voltage regulator and the analog to digital converter. It also provides the reference for the internal voltage regulator. This allows the supply voltage to the ATD and the reference voltage to be bypassed independently.

### 2.4.5 VRH, VRL — ATD Reference Voltage Input Pins

VRH and VRL are the reference voltage input pins for the analog to digital converter.

### 2.4.6 VDDPLL, VSSPLL — Power Supply Pins for PLL

Provides operating voltage and ground for the Oscillator and the Phased-Locked Loop. This allows the supply voltage to the Oscillator and PLL to be bypassed independently. This 2.5V voltage is generated by the internal voltage regulator.

**NOTE:** *No load allowed except for bypass capacitors.*

## Section 4 Modes of Operation

### 4.1 Overview

Eight possible modes determine the operating configuration of the MC9S12DT256. Each mode has an associated default memory map and external bus configuration controlled by a further pin.

Three low power modes exist for the device.

### 4.2 Chip Configuration Summary

The operating mode out of reset is determined by the states of the MODC, MODB, and MODA pins during reset (**Table 4-1**). The MODC, MODB, and MODA bits in the MODE register show the current operating mode and provide limited mode switching during operation. The states of the MODC, MODB, and MODA pins are latched into these bits on the rising edge of the reset signal. The ROMCTL signal allows the setting of the ROMON bit in the MISC register thus controlling whether the internal Flash is visible in the memory map. ROMON = 1 mean the Flash is visible in the memory map. The state of the ROMCTL pin is latched into the ROMON bit in the MISC register on the rising edge of the reset signal.

**Table 4-1 Mode Selection**

BKGD = MODC	PE6 = MODB	PE5 = MODA	PK7 = ROMCTL	ROMON Bit	Mode Description

			1	0	
0	1	0	X	0	Special Test (Expanded Wide), BDM allowed
0	1	1	0	1	Emulation Expanded Wide, BDM allowed

			1	1	

For further explanation on the modes refer to the Core User Guide.

## 4.3 Security

The device will make available a security feature preventing the unauthorized read and write of the memory contents. This feature allows:

- Protection of the contents of FLASH,
- Protection of the contents of EEPROM,
- Operation in single-chip mode,
- Operation from external memory with internal FLASH and EEPROM disabled.

The user must be reminded that part of the security must lie with the user's code. An extreme example would be user's code that dumps the contents of the internal program. This code would defeat the purpose of security. At the same time the user may also wish to put a back door in the user's program. An example of this is the user downloads a key through the SCI which allows access to a programming routine that updates parameters stored in EEPROM.

### 4.3.1 Securing the Microcontroller

Once the user has programmed the FLASH and EEPROM (if desired), the part can be secured by programming the security bits located in the FLASH module. These non-volatile bits will keep the part secured through resetting the part and through powering down the part.

The security byte resides in a portion of the Flash array.

Check the Flash Block User Guide for more details on the security configuration.

### 4.3.2 Operation of the Secured Microcontroller

#### 4.3.2.1 Normal Single Chip Mode

This will be the most common usage of the secured part. Everything will appear the same as if the part was not secured with the exception of BDM operation. The BDM operation will be blocked.

### 4.3.2.2 Executing from External Memory

The user may wish to execute from external space with a secured microcontroller. This is accomplished by resetting directly into expanded mode. The internal FLASH and EEPROM will be disabled. BDM operations will be blocked.

### 4.3.3 Unsecuring the Microcontroller

In order to unsecure the microcontroller, the internal FLASH and EEPROM must be erased. This can be done through an external program in expanded mode.

Once the user has erased the FLASH and EEPROM, the part can be reset into special single chip mode. This invokes a program that verifies the erasure of the internal FLASH and EEPROM. Once this program completes, the user can erase and program the FLASH security bits to the unsecured state. This is generally done through the BDM, but the user could also change to expanded mode (by writing the mode bits through the BDM) and jumping to an external program (again through BDM commands). Note that if the part goes through a reset before the security bits are reprogrammed to the unsecure state, the part will be secured again.

## 4.4 Low Power Modes

The microcontroller features three main low power modes. Consult the respective Block User Guide for information on the module behavior in Stop, Pseudo Stop, and Wait Mode. An important source of information about the clock system is the Clock and Reset Generator User Guide (CRG).

### 4.4.1 Stop

Executing the CPU STOP instruction stops all clocks and the oscillator thus putting the chip in fully static mode. Wake up from this mode can be done via reset or external interrupts.

### 4.4.2 Pseudo Stop

This mode is entered by executing the CPU STOP instruction. In this mode the oscillator is still running and the Real Time Interrupt (RTI) or Watchdog (COP) sub module can stay active. Other peripherals are turned off. This mode consumes more current than the full STOP mode, but the wake up time from this mode is significantly shorter.

### 4.4.3 Wait

This mode is entered by executing the CPU WAI instruction. In this mode the CPU will not execute instructions. The internal CPU signals (address and databus) will be fully static. All peripherals stay active. For further power consumption the peripherals can individually turn off their local clocks.

## 4.4.4 Run

Although this is not a low power mode, unused peripheral modules should not be enabled in order to save power.

## Section 15 Flash EEPROM 256K Block Description

The "S12 LRAE" is a generic Load RAM and Execute (LRAE) program which will be programmed into the flash memory of this device during manufacture. This LRAE program will provide greater programming flexibility to the end users by allowing the device to be programmed directly using CAN or SCI after it is assembled on the PCB. Use of the LRAE program is at the discretion of the end user and, if not required, it must simply be erased prior to flash programming. For more details of the S12 LRAE and its implementation, please see the S12 LREA Application Note (AN2546/D).

It is planned that most HC9S12 devices manufactured after Q1 of 2004 will be shipped with the S12 LRAE programmed in the Flash. Exact details of the changeover (i.e. blank to programmed) for each product will be communicated in advance via GPCN and will be traceable by the customer via datecode marking on the device.

Please contact Motorola SPS Sales if you have any additional questions.

The PCB must be carefully laid out to ensure proper operation of the voltage regulator as well as of the MCU itself. The following rules must be observed:

- Every supply pair must be decoupled by a ceramic capacitor connected as near as possible to the corresponding pins (C1 – C6).
- Central point of the ground star should be the VSSR pin.
- Use low ohmic low inductance connections between VSS1, VSS2 and VSSR.
- VSSPLL must be directly connected to VSSR.
- Keep traces of VSSPLL, EXTAL and XTAL as short as possible and occupied board area for C7, C8, C11 and Q1 as small as possible.
- Do not place other signals or supplies underneath area occupied by C7, C8, C10 and Q1 and the connection area to the MCU.
- Central power input should be fed in at the VDDA/VSSA pins.

# Appendix A Electrical Characteristics

## A.1 General

**NOTE:** *The electrical characteristics given in this section are preliminary and should be used as a guide only. Values cannot be guaranteed by Motorola and are subject to change without notice.*

This supplement contains the most accurate electrical information for the MC9S12DT256 microcontroller available at the time of publication. The information should be considered **PRELIMINARY** and is subject to change.

This introduction is intended to give an overview on several common topics like power supply, current injection etc.

### A.1.1 Parameter Classification

The electrical parameters shown in this supplement are guaranteed by various methods. To give the customer a better understanding the following classification is used and the parameters are tagged accordingly in the tables where appropriate.

**NOTE:** *This classification is shown in the column labeled “C” in the parameter tables where appropriate.*

P:

Those parameters are guaranteed during production testing on each individual device.

C:

Those parameters are achieved by the design characterization by measuring a statistically relevant sample size across process variations.

T:

Those parameters are achieved by design characterization on a small sample size from typical devices under typical conditions unless otherwise noted. All values shown in the typical column are within this category.

D:

Those parameters are derived mainly from simulations.

### A.1.2 Power Supply

The MC9S12DT256 utilizes several pins to supply power to the I/O ports, A/D converter, oscillator and PLL as well as the digital core.

The VDDA, VSSA pair supplies the A/D converter and the resistor ladder of the internal voltage regulator.

The VDDX, VSSX, VDDR and VSSR pairs supply the I/O pins, VDDR supplies also the internal voltage regulator.

VDD1, VSS1, VDD2 and VSS2 are the supply pins for the digital logic, VDDPLL, VSSPLL supply the oscillator and the PLL.

VSS1 and VSS2 are internally connected by metal.

VDDA, VDDX, VDDR as well as VSSA, VSSX, VSSR are connected by anti-parallel diodes for ESD protection.

**NOTE:** *In the following context VDD5 is used for either VDDA, VDDR and VDDX; VSS5 is used for either VSSA, VSSR and VSSX unless otherwise noted. IDD5 denotes the sum of the currents flowing into the VDDA, VDDX and VDDR pins. VDD is used for VDD1, VDD2 and VDDPLL, VSS is used for VSS1, VSS2 and VSSPLL. IDD is used for the sum of the currents flowing into VDD1 and VDD2.*

### A.1.3 Pins

There are four groups of functional pins.

#### A.1.3.1 5V I/O pins

Those I/O pins have a nominal level of 5V. This class of pins is comprised of all port I/O pins, the analog inputs, BKGD and the RESET pins. The internal structure of all those pins is identical, however some of the functionality may be disabled. E.g. for the analog inputs the output drivers, pull-up and pull-down resistors are disabled permanently.

#### A.1.3.2 Analog Reference

This group is made up by the VRH and VRL pins.

#### A.1.3.3 Oscillator

The pins XFC, EXTAL, XTAL dedicated to the oscillator have a nominal 2.5V level. They are supplied by VDDPLL.

#### A.1.3.4 TEST

This pin is used for production testing only.

#### A.1.3.5 VREGEN

This pin is used to enable the on chip voltage regulator.

## A.1.4 Current Injection

Power supply must maintain regulation within operating  $V_{DD5}$  or  $V_{DD}$  range during instantaneous and operating maximum current conditions. If positive injection current ( $V_{in} > V_{DD5}$ ) is greater than  $I_{DD5}$ , the injection current may flow out of VDD5 and could result in external power supply going out of regulation. Ensure external VDD5 load will shunt current greater than maximum injection current. This will be the greatest risk when the MCU is not consuming power; e.g. if no system clock is present, or if clock rate is very low which would reduce overall power consumption.

## A.1.5 Absolute Maximum Ratings

Absolute maximum ratings are stress ratings only. A functional operation under or outside those maxima is not guaranteed. Stress beyond those limits may affect the reliability or cause permanent damage of the device.

This device contains circuitry protecting against damage due to high static voltage or electrical fields; however, it is advised that normal precautions be taken to avoid application of any voltages higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are tied to an appropriate logic voltage level (e.g., either  $V_{SS5}$  or  $V_{DD5}$ ).

**Table A-1 Absolute Maximum Ratings<sup>1</sup>**

NOTES:

1. Beyond absolute maximum ratings device might be damaged.

2. The device contains an internal voltage regulator to generate the logic and PLL supply out of the I/O supply.  
The absolute maximum ratings apply when the device is powered from an external source.
3. All digital I/O pins are internally clamped to  $V_{SSX}$  and  $V_{DDX}$ ,  $V_{SSR}$  and  $V_{DDR}$  or  $V_{SSA}$  and  $V_{DDA}$ .
4. Those pins are internally clamped to  $V_{SSPLL}$  and  $V_{DDPLL}$ .
5. This pin is clamped low to  $V_{SSR}$ , but not clamped high. This pin must be tied low in applications.

## A.1.6 ESD Protection and Latch-up Immunity

All ESD testing is in conformity with CDF-AEC-Q100 Stress test qualification for Automotive Grade Integrated Circuits. During the device qualification ESD stresses were performed for the Human Body Model (HBM), the Machine Model (MM) and the Charge Device Model.

A device will be defined as a failure if after exposure to ESD pulses the device no longer meets the device specification. Complete DC parametric and functional testing is performed per the applicable device specification at room temperature followed by hot temperature, unless specified otherwise in the device specification.

2. Please refer to **Section A.1.8 Power Dissipation and Thermal Characteristics** for more details about the relation between ambient temperature  $T_A$  and device junction temperature  $T_J$ .

## A.1.8 Power Dissipation and Thermal Characteristics

Power dissipation and thermal characteristics are closely related. The user must assure that the maximum operating junction temperature is not exceeded. The average chip-junction temperature ( $T_J$ ) in °C can be obtained from:

$$T_J = T_A + (P_D \cdot \Theta_{JA})$$

$T_J$  = Junction Temperature, [°C]

$T_A$  = Ambient Temperature, [°C]

$P_D$  = Total Chip Power Dissipation, [W]

$\Theta_{JA}$  = Package Thermal Resistance, [°C/W]

The total power dissipation can be calculated from:

$$P_D = P_{INT} + P_{IO}$$

$P_{INT}$  = Chip Internal Power Dissipation, [W]

Two cases with internal voltage regulator enabled and disabled must be considered:

1. Internal Voltage Regulator disabled

$$P_{INT} = I_{DD} \cdot V_{DD} + I_{DDPLL} \cdot V_{DDPLL} + I_{DDA} \cdot V_{DDA}$$

$$P_{IO} = \sum_i R_{DSON} \cdot I_{IO_i}^2$$

$P_{IO}$  is the sum of all output currents on I/O ports associated with VDDX and VDDR.

For  $R_{DSON}$  is valid:

$$R_{DSON} = \frac{V_{OL}}{I_{OL}}; \text{for outputs driven low}$$

respectively

$$R_{DSON} = \frac{V_{DD5} - V_{OH}}{I_{OH}}; \text{for outputs driven high}$$

2. Internal voltage regulator enabled

$$P_{INT} = I_{DDR} \cdot V_{DDR} + I_{DDA} \cdot V_{DDA}$$

$I_{DDR}$  is the current shown in **Table A-7** and not the overall current flowing into VDDR, which additionally contains the current flowing into the external loads with output high.

$$P_{IO} = \sum_i R_{DSON} \cdot I_{IO_i}^2$$

$P_{IO}$  is the sum of all output currents on I/O ports associated with VDDX and VDDR.

## NOTES:

1. Maximum leakage current occurs at maximum operating temperature. Current decreases by approximately one-half for each 8 C to 12 C in the temperature range from 50 C to 125 C.
2. Refer to **Section A.1.4 Current Injection**, for more details
3. Parameter only applies in STOP or Pseudo STOP mode.

## A.1.10 Supply Currents

This section describes the current consumption characteristics of the device as well as the conditions for the measurements.

### A.1.10.1 Measurement Conditions

All measurements are without output loads. Unless otherwise noted the currents are measured in single chip mode, internal voltage regulator enabled and at 25MHz bus frequency using a 4MHz oscillator in Colpitts mode. Production testing is performed using a square wave signal at the EXTAL input.

### A.1.10.2 Additional Remarks

In expanded modes the currents flowing in the system are highly dependent on the load at the address, data and control signals as well as on the duty cycle of those signals. No generally applicable numbers can be

given. A very good estimate is to take the single chip currents and add the currents due to the external loads.

## A.2 ATD Characteristics

This section describes the characteristics of the analog to digital converter.

### A.2.1 ATD Operating Characteristics

The **Table A-8** shows conditions under which the ATD operates.

The following constraints exist to obtain full-scale, full range results:

$V_{SSA} \leq V_{RL} \leq V_{IN} \leq V_{RH} \leq V_{DDA}$ . This constraint exists since the sample buffer amplifier can not drive beyond the power supply levels that it ties to. If the input level goes outside of this range it will effectively be clipped.

**Table A-8 ATD Operating Characteristics**

Conditions are shown in <b>Table A-4</b> unless otherwise noted							
Num	C	Rating	Symbol	Min	Typ	Max	Unit
1	D	Reference Potential	Low	$V_{RL}$	$V_{SSA}$	$V_{DDA}/2$	V
			High	$V_{RH}$	$V_{DDA}/2$	$V_{DDA}$	V
2	C	Differential Reference Voltage <sup>1</sup>	$V_{RH}-V_{RL}$	4.50	5.00	5.25	V

5	D	ATD 8-Bit Conversion Period	Clock Cycles <sup>2</sup> Conv, Time at 2.0MHz ATD Clock $f_{ATDCLK}$	$N_{CONV8}$	12	26	Cycles $\mu$ s
				$T_{CONV8}$	6	13	
6	D	Recovery Time ( $V_{DDA}=5.0$ Volts)	$t_{REC}$			20	$\mu$ s
7	P	Reference Supply current 2 ATD blocks on	$I_{REF}$			0.750	mA
8	P	Reference Supply current 1 ATD block on	$I_{REF}$			0.375	mA

NOTES:

1. Full accuracy is not guaranteed when differential voltage is less than 4.50V
2. The minimum time assumes a final sample period of 2 ATD clocks cycles while the maximum time assumes a final sample period of 16 ATD clocks.

### A.2.2 Factors influencing accuracy

Three factors - source resistance, source capacitance and current injection - have an influence on the accuracy of the ATD.

#### A.2.2.1 Source Resistance:

Due to the input pin leakage current as specified in **Table A-6** in conjunction with the source resistance there will be a voltage drop from the signal source to the ATD input. The maximum source resistance  $R_S$

specifies results in an error of less than 1/2 LSB (2.5mV) at the maximum leakage current. If device or operating conditions are less than worst case or leakage-induced error is acceptable, larger values of source resistance is allowed.

### A.2.2.2 Source Capacitance

When sampling an additional internal capacitor is switched to the input. This can cause a voltage drop due to charge sharing with the external and the pin capacitance. For a maximum sampling error of the input voltage  $\leq 1\text{LSB}$ , then the external filter capacitor,  $C_f \geq 1024 * (C_{\text{INS}} - C_{\text{INN}})$ .

### A.2.2.3 Current Injection

There are two cases to consider.

1. A current is injected into the channel being converted. The channel being stressed has conversion values of \$3FF (\$FF in 8-bit mode) for analog inputs greater than  $V_{\text{RH}}$  and \$000 for values less than  $V_{\text{RL}}$  unless the current is higher than specified as disruptive condition.
2. Current is injected into pins in the neighborhood of the channel being converted. A portion of this current is picked up by the channel (coupling ratio K), This additional current impacts the accuracy of the conversion depending on the source resistance.

The additional input voltage error on the converted channel can be calculated as  $V_{\text{ERR}} = K * R_S * I_{\text{INJ}}$ , with  $I_{\text{INJ}}$  being the sum of the currents injected into the two pins adjacent to the converted channel.

**Table A-9 ATD Electrical Characteristics**

Conditions are shown in <b>Table A-4</b> unless otherwise noted							
Num	C	Rating	Symbol	Min	Typ	Max	Unit
1	C	Max input Source Resistance	$R_S$	-	-	1	$K\Omega$
2	T	Total Input Capacitance Non Sampling Sampling	$C_{\text{INN}}$ $C_{\text{INS}}$			10 22	pF
3	C	Disruptive Analog Input Current	$I_{\text{NA}}$	-2.5		2.5	mA
4	C	Coupling Ratio positive current injection	$K_p$			$10^{-4}$	A/A
5	C	Coupling Ratio negative current injection	$K_n$			$10^{-2}$	A/A

## A.2.3 ATD accuracy

**Table A-10** specifies the ATD conversion performance excluding any errors due to current injection, input capacitance and source resistance.

**Table A-10 ATD Conversion Performance**

Conditions are shown in <b>Table A-4</b> unless otherwise noted $V_{REF} = V_{RH} - V_{RL} = 5.12V$ . Resulting to one 8 bit count = 20mV and one 10 bit count = 5mV $f_{ATDCLK} = 2.0MHz$

NOTES:

1. These values include the quantization error which is inherently 1/2 count for any A/D converter.

For the following definitions see also **Figure A-1**.

Differential Non-Linearity (DNL) is defined as the difference between two adjacent switching steps.

$$DNL(i) = \frac{V_i - V_{i-1}}{1LSB} - 1$$

The Integral Non-Linearity (INL) is defined as the sum of all DNLs:

$$INL(n) = \sum_{i=1}^n DNL(i) = \frac{V_n - V_0}{1LSB} - n$$

## A.3 NVM, Flash and EEPROM

**NOTE:** Unless otherwise noted the abbreviation NVM (Non Volatile Memory) is used for both Flash and EEPROM.

### A.3.1 NVM timing

The time base for all NVM program or erase operations is derived from the oscillator. A minimum oscillator frequency  $f_{\text{NVMOSC}}$  is required for performing program or erase operations. The NVM modules do not have any means to monitor the frequency and will not prevent program or erase operation at frequencies above or below the specified minimum. Attempting to program or erase the NVM modules at a lower frequency a full program or erase transition is not assured.

The Flash and EEPROM program and erase operations are timed using a clock derived from the oscillator using the FCLKDIV and ECLKDIV registers respectively. The frequency of this clock must be set within the limits specified as  $f_{\text{NVMOP}}$ .

The minimum program and erase times shown in **Table A-11** are calculated for maximum  $f_{\text{NVMOP}}$  and maximum  $f_{\text{bus}}$ . The maximum times are calculated for minimum  $f_{\text{NVMOP}}$  and a  $f_{\text{bus}}$  of 2MHz.

#### A.3.1.1 Single Word Programming

The programming time for single word programming is dependant on the bus frequency as a well as on the frequency  $f_{\text{NVMOP}}$  and can be calculated according to the following formula.

$$t_{\text{swpgm}} = 9 \cdot \frac{1}{f_{\text{NVMOP}}} + 25 \cdot \frac{1}{f_{\text{bus}}}$$

#### A.3.1.2 Burst Programming

This applies only to the Flash where up to 32 words in a row can be programmed consecutively using burst programming by keeping the command pipeline filled. The time to program a consecutive word can be calculated as:

$$t_{\text{bwpgm}} = 4 \cdot \frac{1}{f_{\text{NVMOP}}} + 9 \cdot \frac{1}{f_{\text{bus}}}$$

The time to program a whole row is:

$$t_{\text{brpgm}} = t_{\text{swpgm}} + 31 \cdot t_{\text{bwpgm}}$$

Burst programming is more than 2 times faster than single word programming.

### A.3.1.3 Sector Erase

Erasing a 512 byte Flash sector or a 4 byte EEPROM sector takes:

$$t_{\text{era}} \approx 4000 \cdot \frac{1}{f_{\text{NVMOP}}}$$

The setup time can be ignored for this operation.

### A.3.1.4 Mass Erase

Erasing a NVM block takes:

$$t_{\text{mass}} \approx 20000 \cdot \frac{1}{f_{\text{NVMOP}}}$$

The setup time can be ignored for this operation.

### A.3.1.5 Blank Check

The time it takes to perform a blank check on the Flash or EEPROM is dependant on the **location** of the first non-blank word starting at relative address zero. It takes one bus cycle per word to verify plus a setup of the command.

$$t_{\text{check}} \approx \text{location} \cdot t_{\text{cyc}} + 10 \cdot t_{\text{cyc}}$$

10	D	Blank Check Time EEPROM per block	$t_{\text{check}}$	11 <sup>6</sup>		2058 <sup>7</sup>	$t_{\text{cyc}}$

NOTES:

- Restrictions for oscillator in crystal mode apply!
- Minimum Programming times are achieved under maximum NVM operating frequency  $f_{\text{NVMOP}}$  and maximum bus frequency  $f_{\text{bus}}$ .

3. Maximum Erase and Programming times are achieved under particular combinations of  $f_{\text{NVMOP}}$  and bus frequency  $f_{\text{bus}}$ . Refer to formulae in Sections **A.3.1.1 - A.3.1.4** for guidance.
4. Burst Programming operations are not applicable to EEPROM
5. Minimum Erase times are achieved under maximum NVM operating frequency  $f_{\text{NVMOP}}$ .
6. Minimum time, if first word in the array is not blank
7. Maximum time to complete check on an erased block

## A.3.2 NVM Reliability

The reliability of the NVM blocks is guaranteed by stress test during qualification, constant process monitors and burn-in to screen early life failures. The program/erase cycle count on the sector is incremented every time a sector or mass erase event is executed

- Typical data retention values are based on intrinsic capability of the technology measured at high temperature and de-rated to  $25^{\circ}\text{C}$  using the Arrhenius equation. ## A.4 Voltage Regulator

The on-chip voltage regulator is intended to supply the internal logic and oscillator circuits. No external DC load is allowed.

**Table A-13 Voltage Regulator Recommended Load Capacitances**

## A.5 Reset, Oscillator and PLL

This section summarizes the electrical characteristics of the various startup scenarios for Oscillator and Phase-Locked-Loop (PLL).

### A.5.1 Startup

**Table A-14** summarizes several startup characteristics explained in this section. Detailed description of the startup behavior can be found in the Clock and Reset Generator (CRG) Block Guide.

**Table A-14 Startup Characteristics**

Conditions are shown in <b>Table A-4</b> unless otherwise noted							
Num	C	Rating	Symbol	Min	Typ	Max	Unit
1	T	POR release level	$V_{PORR}$			2.07	V
2	T	POR assert level	$V_{PORA}$	0.97			V
3	D	Reset input pulse width, minimum input time	$PW_{RSTL}$	2			$t_{osc}$
4	D	Startup from Reset	$n_{RST}$	192		196	$n_{osc}$
5	D	Interrupt pulse width, $\overline{IRQ}$ edge-sensitive mode	$PW_{IRQ}$	20			ns
6	D	Wait recovery startup time	$t_{WRS}$			14	$t_{cyc}$

#### A.5.1.1 POR

The release level  $V_{PORR}$  and the assert level  $V_{PORA}$  are derived from the  $V_{DD}$  Supply. They are also valid if the device is powered externally. After releasing the POR reset the oscillator and the clock quality check are started. If after a time  $t_{CQOUT}$  no valid oscillation is detected, the MCU will start using the internal self clock. The fastest startup time possible is given by  $n_{uposc}$ .

#### A.5.1.2 SRAM Data Retention

Provided an appropriate external reset signal is applied to the MCU, preventing the CPU from executing code when  $V_{DD5}$  is out of specification limits, the SRAM contents integrity is guaranteed if after the reset the PORF bit in the CRG Flags Register has not been set.

#### A.5.1.3 External Reset

When external reset is asserted for a time greater than  $PW_{RSTL}$  the CRG module generates an internal reset, and the CPU starts fetching the reset vector without doing a clock quality check, if there was an oscillation before reset.

#### A.5.1.4 Stop Recovery

Out of STOP the controller can be woken up by an external interrupt. A clock quality check as after POR is performed before releasing the clocks to the system.

### A.5.1.5 Pseudo Stop and Wait Recovery

The recovery from Pseudo STOP and Wait are essentially the same since the oscillator was not stopped in both modes. The controller can be woken up by internal or external interrupts. After  $t_{wrs}$  the CPU starts fetching the interrupt vector.

## A.5.2 Oscillator

The device features an internal Colpitts and Pierce oscillator. The selection of Colpitts oscillator or Pierce oscillator/external clock depends on the  $\overline{XCLKS}$  signal which is sampled during reset. By asserting the  $\overline{XCLKS}$  input during reset this oscillator can be bypassed allowing the input of a square wave. Before asserting the oscillator to the internal system clocks the quality of the oscillation is checked for each start from either power-on, STOP or oscillator fail.  $t_{CQOUT}$  specifies the maximum time before switching to the internal self clock mode after POR or STOP if a proper oscillation is not detected. The quality check also determines the minimum oscillator start-up time  $t_{UPOSC}$ . The device also features a clock monitor. A Clock Monitor Failure is asserted if the frequency of the incoming clock signal is below the Assert Frequency  $f_{CMFA}$ .

**Table A-15 Oscillator Characteristics**

Conditions are shown in <b>Table A-4</b> unless otherwise noted							
Num	C	Rating	Symbol	Min	Typ	Max	Unit
1a	C	Crystal oscillator range (Colpitts)	$f_{OSC}$	0.5		16	MHz
1b	C	Crystal oscillator range (Pierce) <sup>1(4)</sup>	$f_{OSC}$	0.5		40	MHz
2	P	Startup Current	$i_{OSC}$	100			$\mu A$
3	C	Oscillator start-up time (Colpitts)	$t_{UPOSC}$		$8^2$	$100^3$	ms
4	D	Clock Quality check time-out	$t_{CQOUT}$	0.45		2.5	s
5	P	Clock Monitor Failure Assert Frequency	$f_{CMFA}$	50	100	200	KHz
6	P	External square wave input frequency <sup>4</sup>	$f_{EXT}$	0.5		50	MHz
7	D	External square wave pulse width low	$t_{EXTL}$	9.5			ns
8	D	External square wave pulse width high	$t_{EXTH}$	9.5			ns
9	D	External square wave rise time	$t_{EXTR}$			1	ns
10	D	External square wave fall time	$t_{EXTF}$			1	ns
11	D	Input Capacitance (EXTAL, XTAL pins)	$C_{IN}$		7		pF
12	C	DC Operating Bias in Colpitts Configuration on EXTAL Pin	$V_{DCBIAS}$		1.1		V

**NOTES:**

1. Depending on the crystal a damping series resistor might be necessary
2.  $f_{osc} = 4\text{MHz}$ ,  $C = 22\text{pF}$ .
3. Maximum value is for extreme cases using high Q, low frequency crystals
4.  $\overline{XCLKS} = 0$  during reset

### A.5.3 Phase Locked Loop

The oscillator provides the reference clock for the PLL. The PLL's Voltage Controlled Oscillator (VCO) is also the system clock source in self clock mode.

#### A.5.3.1 XFC Component Selection

This section describes the selection of the XFC components to achieve a good filter characteristics.

**Figure A-3 Basic PLL functional diagram**

The following procedure can be used to calculate the resistance and capacitance values using typical values for  $K_1$ ,  $f_1$  and  $i_{ch}$  from **Table A-16**.

The grey boxes show the calculation for  $f_{VCO} = 50\text{MHz}$  and  $f_{ref} = 1\text{MHz}$ . E.g., these frequencies are used for  $f_{OSC} = 4\text{MHz}$  and a  $25\text{MHz}$  bus clock.

The VCO Gain at the desired VCO frequency is approximated by:

$$K_V = K_1 \cdot e^{\frac{(f_1 - f_{VCO})}{K_1 \cdot 1V}} = -100 \cdot e^{\frac{(60 - 50)}{-100}} = -90.48\text{MHz/V}$$

The phase detector relationship is given by:

$$K_\Phi = -|i_{ch}| \cdot K_V = 316.7\text{Hz}/\Omega$$

$i_{ch}$  is the current in tracking mode.

The loop bandwidth  $f_C$  should be chosen to fulfill the Gardner's stability criteria by at least a factor of 10, typical values are 50.  $\zeta = 0.9$  ensures a good transient response.

$$f_C < \frac{2 \cdot \zeta \cdot f_{\text{ref}}}{\pi \cdot (\zeta + \sqrt{1 + \zeta^2})} \cdot \frac{1}{10} \rightarrow f_C < \frac{f_{\text{ref}}}{4 \cdot 10}; (\zeta = 0.9)$$

$$f_C < 25\text{kHz}$$

And finally the frequency relationship is defined as

$$n = \frac{f_{\text{VCO}}}{f_{\text{ref}}} = 2 \cdot (\text{synr} + 1) = 50$$

With the above values the resistance can be calculated. The example is shown for a loop bandwidth  $f_C=10\text{kHz}$ :

$$R = \frac{2 \cdot \pi \cdot n \cdot f_C}{K_\Phi} = 2 \cdot \pi \cdot 50 \cdot 10\text{kHz} / (316.7\text{Hz}/\Omega) = 9.9\text{k}\Omega \approx 10\text{k}\Omega$$

The capacitance  $C_s$  can now be calculated as:

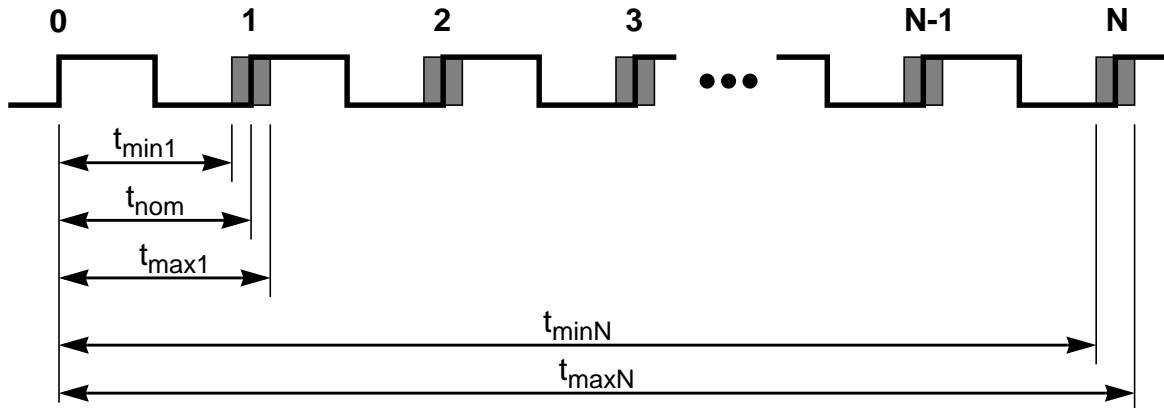

$$C_s = \frac{2 \cdot \zeta^2}{\pi \cdot f_C \cdot R} \approx \frac{0.516}{f_C \cdot R}; (\zeta = 0.9) = 5.19\text{nF} \approx 4.7\text{nF}$$

The capacitance  $C_p$  should be chosen in the range of:

$$C_s / 20 \leq C_p \leq C_s / 10 \quad C_p = 470\text{pF}$$

### A.5.3.2 Jitter Information

The basic functionality of the PLL is shown in **Figure A-3**. With each transition of the clock  $f_{\text{cmp}}$ , the deviation from the reference clock  $f_{\text{ref}}$  is measured and input voltage to the VCO is adjusted accordingly. The adjustment is done continuously with no abrupt changes in the clock output frequency. Noise, voltage, temperature and other factors cause slight variations in the control loop resulting in a clock jitter. This jitter affects the real minimum and maximum clock periods as illustrated in **Figure A-4**.

**Figure A-4 Jitter Definitions**

The relative deviation of  $t_{nom}$  is at its maximum for one clock period, and decreases towards zero for larger number of clock periods ( $N$ ).

Defining the jitter as:

$$J(N) = \max\left(\left|1 - \frac{t_{max}(N)}{N \cdot t_{nom}}\right|, \left|1 - \frac{t_{min}(N)}{N \cdot t_{nom}}\right|\right)$$

For  $N < 100$ , the following equation is a good fit for the maximum jitter:

$$J(N) = \frac{j_1}{\sqrt{N}} + j_2$$

**Figure A-5 Maximum bus clock jitter approximation**

This is very important to notice with respect to timers, serial modules where a pre-scaler will eliminate the effect of the jitter to a large extent.
