

## 256K x 36, 512K x 18 3.3V Synchronous ZBT<sup>™</sup>SRAMs 2.5V I/O, Burst Counter Pipelined Outputs

## **Features**

- 256K x 36, 512K x 18 memory configurations
- Supports high performance system speed 150MHz (3.8ns Clock-to-Data Access)
- ◆ ZBT<sup>TM</sup> Feature No dead cycles between write and read cycles
- Internally synchronized output buffer enable eliminates the need to control OE
- Single R/W (READ/WRITE) control pin
- Positive clock-edge triggered address, data, and control signal registers for fully pipelined applications
- 4-word burst capability (interleaved or linear)
- Individual byte write (BW1 BW4) control (May tie active)
- Three chip enables for simple depth expansion
- 3.3V power supply (±5%)
- 2.5V I/O Supply (VDDQ)
- Power down controlled by ZZ input
- Packaged in a JEDEC standard 100-pin plastic thin quad and flatpack (TQFP), 119 ball grid array (BGA) and 165 fine pitch ball grid array (fBGA)

# Description

The IDT71V65602/5802 are 3.3V high-speed 9,437,184-bit (9 Megabit) synchronous SRAMs. They are designed to eliminate dead bus cycles when turning the bus around between reads and writes, or writes and reads. Thus, they have been given the name ZBT<sup>TM</sup>, or Zero Bus Turnaround.

Address and control signals are applied to the SRAM during one clock cycle, and two cycles later the associated data cycle occurs, be it read or write.

The IDT71V65602/5802 contain data I/O, address and control signal registers. Output enable is the only asynchronous signal and can be used to disable the outputs at any given time.

A Clock Enable (CEN) pin allows operation of the IDT71V65602/5802 to be suspended as long as necessary. All synchronous inputs are ignored when (CEN) is high and the internal device registers will hold their previous values.

There are three chip enable pins ( $\overline{CE}_1$ , CE<sub>2</sub>,  $\overline{CE}_2$ ) that allow the user to deselect the device when desired. If any one of these three are not asserted when ADV/ $\overline{LD}$  is low, no new memory operation can be initiated. However, any pending data transfers (reads or writes) will be completed. The data bus will tri-state two cycles after chip is deselected or a write is initiated.

The IDT71V65602/5802 have an on-chip burst counter. In the burst mode, the IDT71V65602/5802 can provide four cycles of data for a single address presented to the SRAM. The order of the burst sequence is defined by the LBO input pin. The LBO pin selects between linear and interleaved burst sequence. The ADV/LD signal is used to load a new external address (ADV/LD = LOW) or increment the internal burst counter (ADV/LD = HIGH).

The IDT71V65602/5802 SRAM utilize IDT's latest high-performance CMOS process, and are packaged in a JEDEC Standard 14mm x 20mm 100pin thin plastic quad flatpack (TQFP) as well as a 119 ball grid array (BGA) and a 165 fine pitch ball grid array (fBGA).

| A0-A18  | Address Inputs                           | Input  | Synchronous  |
|---|--|--------|--------------|
| <u>CE</u> 1, CE2, <u>CE</u> 2   | Chip Enables                             | Input  | Synchronous  |
| ŌĒ  | Output Enable                            | Input  | Asynchronous |
| R/W   | Read/Write Signal                        | Input  | Synchronous  |
| CEN   | Clock Enable                             | Input  | Synchronous  |
| $\overline{BW}_{1}$ , $\overline{BW}_{2}$ , $\overline{BW}_{3}$ , $\overline{BW}_{4}$ | Individual Byte Write Selects            | Input  | Synchronous  |
| CLK   | Clock                                    | Input  | N/A          |
| ADV/LD  | Advance burst address / Load new address | Input  | Synchronous  |
| LBO   | Linear / Interleaved Burst Order         | Input  | Static       |
| ZZ  | Sleep Mode                               | Input  | Asynchronous |
| I/O0-I/O31, I/OP1-I/OP4   | Data Input / Output                      | I/O    | Synchronous  |
| VDD, VDDQ   | Core Power, I/O Power                    | Supply | Static       |
| Vss   | Ground                                   | Supply | Static       |

# Pin Definitions<sup>(1)</sup>

| Symbol                | Pin Function                     | I/O | Active | Description   |
|-----------------------|----------------------------------|-----|--------|---|
| A0-A18                | Address Inputs                   | -   | N/A    | Synchronous Address inputs. The address register is triggered by a combination of the rising edge of CLK, $ADV/\overline{LD}$ low, $\overline{CEN}$ low, and true chip enables.   |
| ADV/LD                | Advance / Load                   | Ι   | N/A    | $ADV/\overline{LD}$ is a synchronous input that is used to load the internal registers with new address and control when it is sampled low at the rising edge of clock with the chip selected. When $ADV/\overline{LD}$ is low with the chip deselected, any burst in progress is terminated. When $ADV/\overline{LD}$ is sampled high then the internal burst counter is advanced for any burst that was in progress. The external addresses are ignored when $ADV/\overline{LD}$ is sampled high.   |
| R∕₩                   | Read / Write                     | Ι   | N/A    | $R/\overline{W}$ signal is a synchronous input that identifies whether the current load cycle initiated is a Read or Write access to the memory array. The data bus activity for the current cycle takes place two clock cycles later.  |
| CEN                   | Clock Enable                     | Ι   | LOW    | Synchronous Clock Enable Input. When $\overline{\text{CEN}}$ is sampled high, all other synchronous inputs, including clock are ignored and outputs remain unchanged. The effect of $\overline{\text{CEN}}$ sampled high on the device outputs is as if the low to high clock transition did not occur. For normal operation, $\overline{\text{CEN}}$ must be sampled low at rising edge of clock.  |
| BW1-BW4               | Individual Byte<br>Write Enables | _   | LOW    | Synchronous byte write enables. Each 9-bit byte has its own active low byte write enable. On load write cycles (When $R/\overline{W}$ and $ADV/\overline{LD}$ are sampled low) the appropriate byte write signal ( $\overline{BW}_{1}$ - $\overline{BW}_{4}$ ) must be valid. The byte write signal must also be valid on each cycle of a burst write. Byte Write signals are ignored when $R/\overline{W}$ is sampled high. The appropriate byte(s) of data are written into the device two cycles later. $\overline{BW}_{1}$ - $\overline{BW}_{4}$ can all be tied low if always doing write to the entire 36-bit word. |
| CE1, CE2              | Chip Enables                     | I   | LOW    | Synchronous active low chip enable. $\overline{CE}_1$ and $\overline{CE}_2$ are used with CE <sub>2</sub> to enable the IDT71V65602/5802. ( $\overline{CE}_1$ or $\overline{CE}_2$ sampled high or CE <sub>2</sub> sampled low) and ADV/LD low at the rising edge of clock, initiates a deselect cycle. The ZBT <sup>M</sup> has a two cycle deselect, i.e., the data bus will tri-state two clock cycles after deselect is initiated.  |
| CE2                   | Chip Enable                      | Ι   | HIGH   | Synchronous active high chip enable. CE <sub>2</sub> is used with $\overline{CE}_1$ and $\overline{CE}_2$ to enable the chip. CE <sub>2</sub> has inverted polarity but otherwise identical to $\overline{CE}_1$ and $\overline{CE}_2$ .  |
| CLK                   | Clock                            | -   | N/A    | This is the clock input to the IDT71V65602/5802. Except for $\overline{\text{OE}}$ , all timing references for the device are made with respect to the rising edge of CLK.  |
| V00-V031<br>V0p1-V0p4 | Data Input/Output                | I/O | N/A    | Synchronous data input/output (I/O) pins. Both the data input path and data output path are registered and triggered by the rising edge of CLK.   |
| LBO                   | Linear Burst Order               | I   | LOW    | Burst order selection input. When $\overline{\text{LBO}}$ is high the Interleaved burst sequence is selected. When $\overline{\text{LBO}}$ is low the Linear burst sequence is selected. $\overline{\text{LBO}}$ is a static input and it must not change during device operation.  |
| ŌĒ                    | Output Enable                    | I   | LOW    | Asynchronous output enable. $\overline{OE}$ must be low to read data from the IDT71V65602/5802.<br>When $\overline{OE}$ is high the I/O pins are in a high-impedance state. $\overline{OE}$ does not need to be actively controlled for read and write cycles. In normal operation, $\overline{OE}$ can be tied low.  |
| ZZ                    | Sleep Mode                       | I   | HIGH   | Asynchronous sleep mode input. ZZ HIGH will gate the CLK internally and power down 71V65602/5802 to the lowest power consumption level. Data retention is guaranteed in Sleep Mode.   |
| Vdd                   | Power Supply                     | N/A | N/A    | 3.3V core power supply.   |
| VDDQ                  | Power Supply                     | N/A | N/A    | 2.5V I/O Supply.  |
| Vss                   | Ground                           | N/A | N/A    | Ground.   |

NOTE:

1. All synchronous inputs must meet specified setup and hold times with respect to CLK.

# Recommended Operating Temperature and Supply Voltage

| Grade      | Ambient<br>Temperature <sup>(1)</sup> | Vss | Vdd     | Vddq    |
|------------|---------------------------------------|-----|---------|---------|
| Commercial | 0° C to +70° C                        | 0V  | 3.3V±5% | 2.5V±5% |
| Industrial | -40° C to +85° C                      | 0V  | 3.3V±5% | 2.5V±5% |

NOTES:

1. During production testing, the case temperature equals the ambient temperature.

# Pin Configuration - 256K x 36

5303tbl 05

NOTES:

- 1. Pins 14, 16 and 66 do not have to be connected directly to VDD as long as the input voltage is  $\geq$  VIH.
- 2. Pin 84 is reserved for a future 16M.
- 3. DNU=Do not use. Pins 38, 39, 42 and 43 are reserved for respective JTAG pins: TMS, TDI, TDO and TCK. The current die revision allows these pins to be left unconnected, tied Low (Vss) or tied High (Vbb).

#### NOTES:

 Stresses greater than those listed under ABSOLUTE MAXIMUM RATINGS may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

2. VDD terminals only.

- 3. VDDQ terminals only.
- 4. Input terminals only.

5. I/O terminals only.

- 6. This is a steady-state DC parameter that applies after the power supply has reached its nominal operating value. Power sequencing is not necessary; however, the voltage on any input or I/O pin cannot exceed VDDO during power supply ramp up.
- 7. During production testing, the case temperature equals TA.

### NOTES:

- 1. J3, J5, and R5 do not have to be directly connected to VDD as long as the input voltage is  $\geq$  VIH.
- 2. A4 is reserved for future 16M.
- 3. DNU = Do not use. Pin U2, U3, U4, U5 and U6 are reserved for respective JTAG pins: TMS, TDI, TCK, TDO and TRST. The current die revision allows these pins to be left unconnected, tied LOW (Vss), or tied HIGH (VDD).

NOTES:

1. H1, H2, and N7 do not have to be directly connected to VDD as long as the input voltage is  $\geq$  VIH.

2. B9, B11, A1, R2 and P2 is reserved for future 18M, 36M, 72M, 144M and 288M, respectively.

3. DNU=Do not use. Pins P5, R5, P7, R7 and N5 are reserved for respective JTAG pins: TDI, TMS, TDO, TCK and TRST on future revisions. The current die revision allows these pins to be left unconnected, tied LOW (Vss), or tied HIGH (VDD).

#### NOTES:

1. L = VIL, H = VIH, X = Don't Care.

2. When ADV/LD signal is sampled high, the internal burst counter is incremented. The R/W signal is ignored when the counter is advanced. Therefore the nature of the burst cycle (Read or Write) is determined by the status of the R/W signal when the first address is loaded at the beginning of the burst cycle.

 Deselect cycle is initiated when either (CE1, or CE2 is sampled high or CE2 is sampled low) and ADV/LD is sampled low at rising edge of clock. The data bus will tri-state two cycles after deselect is initiated.

4. When CEN is sampled high at the rising edge of clock, that clock edge is blocked from propogating through the part. The state of all the internal registers and the I/ Os remains unchanged.

5. To select the chip requires  $\overline{CE}_1 = L$ ,  $\overline{CE}_2 = L$ ,  $CE_2 = H$  on these chip enables. Chip is deselected if any one of the chip enables is false.

6. Device Outputs are ensured to be in High-Z after the first rising edge of clock upon power-up.

7. Q - Data read from the device, D - data written to the device.

# Partial Truth Table for Writes<sup>(1)</sup>

| OPERATION   | R/ <b>W</b> | <b>BW</b> 1 | <b>BW</b> 2 | <b>BW</b> 3 <sup>(3)</sup> | <b>BW</b> 4 <sup>(3)</sup> |

5303 tbl 11

NOTES:

1. This assumes  $\overline{CEN}$ ,  $\overline{CE}_1$ ,  $CE_2$ ,  $\overline{CE}_2$  are all true.

2. All Address, Control and Data\_in are only required to meet set-up and hold time with respect to the rising edge of clock. Data\_Out is valid after a clock-to-data delay from the rising edge of clock.

1. All values are maximum guaranteed values.

2. At f = fmax, inputs are cycling at the maximum frequency of read cycles of 1/tcyc; f=0 means no input lines are changing.

3. For I/Os VHD = VDDQ - 0.2V, VLD = 0.2V. For other inputs VHD = VDD - 0.2V, VLD = 0.2V.

# **AC Test Conditions** (VDDQ = 2.5V)

5303 tbl 24

1. tF = 1/tcyc. 2. Measured as HIGH above 0.6Vppo and LOW below 0.4Vppo.

3. Transition is measured ±200mV from steady-state.

NOTES:

4. These parameters are guaranteed with the AC load (Figure 1) by device characterization. They are not production tested.

5. To avoid bus contention, the output buffers are designed such that tCHZ (device turn-off) is about 1ns faster than tCLZ (device turn-on) at a given temperature and voltage. The specs as shown do not imply bus contention because tCLZ is a Min. parameter that is worse case at totally different test conditions (0 deg. C, 3.465V) than tCHZ, which is a Max. parameter (worse case at 70 deg. C, 3.135V).

1. Q (A1) represents the first output from the external address A1. Q (A2) represents the first output from the external address A2; Q (A2+1) represents the next output data in the burst sequence

of the base address A2, etc. where address bits A0 and A1 are advancing for the four word burst in the sequence defined by the state of the LBO input. CE2 timing transitions are identical but inverted to the  $\overline{CE}_1$  and  $\overline{CE}_2$  signals. For example, when  $\overline{CE}_1$  and  $\overline{CE}_2$  are LOW on this waveform, CE2 is HIGH.

2. CE2 timing transitions are identical but inverted to ure verticative vectors of the SRAM by sampling ADV/LD LOW. 3. Burst ends when new address and control are loaded into the SRAM by sampling ADV/LD LOW. 4. R/W is don't care when the SRAM is bursting (ADV/LD sampled HIGH). The nature of the burst access (Read or Write) is fixed by the state of the R/W signal when new address

# Timing Waveform of Read Cycle<sup>(1,2,3,4)</sup>

- 1. D (A1) represents the first input to the external address A1. D (A2) represents the first input to the external address A2; D (A2+1) represents the next input data in the burst sequence of the base address A2, etc. where address bits Ao and A1 are advancing for the four word burst in the sequence defined by the state of the LBO input.
- 2. CE2 timing transitions are identical but inverted to the CE1 and CE2 signals. For example, when CE1 and CE2 are LOW on this waveform, CE2 is HIGH.
- 3. Burst ends when new address and control are loaded into the SRAM by sampling ADV/LD LOW.
- 4. R/W is don't care when the SRAM is bursting (ADV/LD sampled HIGH). The nature of the burst access (Read or Write) is fixed by the state of the R/W signal when new address and control are loaded into the SRAM.
- 5. Individual Byte Write signals (BWx) must be valid on all write and burst-write cycles. A write cycle is initiated when RIW signal is sampled LOW. The byte write information comes in two cycles before the actual data is presented to the SRAM.

Q (A1) represents the first output from the external address A1. D (A2) represents the input data to the SRAM corresponding to address A2.
CE2 timing transitions are identical but inverted to the CE1 and CE2 signals. For example, when CE1 and CE2 are LOW on this waveform, CE2 is HIGH.

3. Individual Byte Write signals (BWx) must be valid on all write and burst-write cycles. A write cycle is initiated when R/W signal is sampled LOW. The byte write information comes in two cycles before the actual data is presented to the SRAM.

6

IDT71V65602, IDT71V65802, 256K x 36, 512K x 18, 3.3V Synchronous SRAMs with ZBT™ Feature, 2.5V I/O, Burst Counter, and Pipelined Outputs Commercial and Industrial Temperature Ranges

- 1. Q (A1) represents the first output from the external address A1. D (A2) represents the input data to the SRAM corresponding to address A2. 2. CE2 timing transitions are identical but inverted to the  $\overline{CE_1}$  and  $\overline{CE_2}$  signals. For example, when  $\overline{CE_1}$  and  $\overline{CE_2}$  are LOW on this waveform, CE2 is HIGH.
- 3. CEN when sampled high on the rising edge of clock will block that L-H transition of the clock from propogating into the SRAM. The part will behave as if the L-H clock transition did not occur. All internal registers in the SRAM will retain their previous state.
- 4. Individual Byte Write signals (BWx) must be valid on all write and burst-write cycles. A write cycle is initiated when R/W signal is sampled LOW. The byte write information comes in two cycles before the actual data is presented to the SRAM.

IDT71V65602, IDT71V65802, 256K x 36, 512K x 18, 3.3V Synchronous SRAMs with ZBT™ Feature, 2.5V I/O, Burst Counter, and Pipelined Outputs Commercial and Industrial Temperature Ranges

1.  $Q(A_1)$  represents the first output from the external address A<sub>1</sub>.  $D(A_3)$  represents the input data to the SRAM corresponding to address A<sub>3</sub>. 2. CE<sub>2</sub> timing transitions are identical but inverted to the  $\overline{CE_1}$  and  $\overline{CE_2}$  signals. For example, when  $\overline{CE_1}$  and  $\overline{CE_2}$  are LOW on this waveform, CE<sub>2</sub> is HIGH. 3.  $\overline{CEN}$  when sampled high on the rising edge of clock will block that L-H transition of the clock from propogating into the SRAM. The part will behave as if the L-H clock transition did not

occur. All internal registers in the SRAM will retain their previous state.
