## APPLICATIONS:

- 3.3V High Speed Bus Switching and Bus Isolation

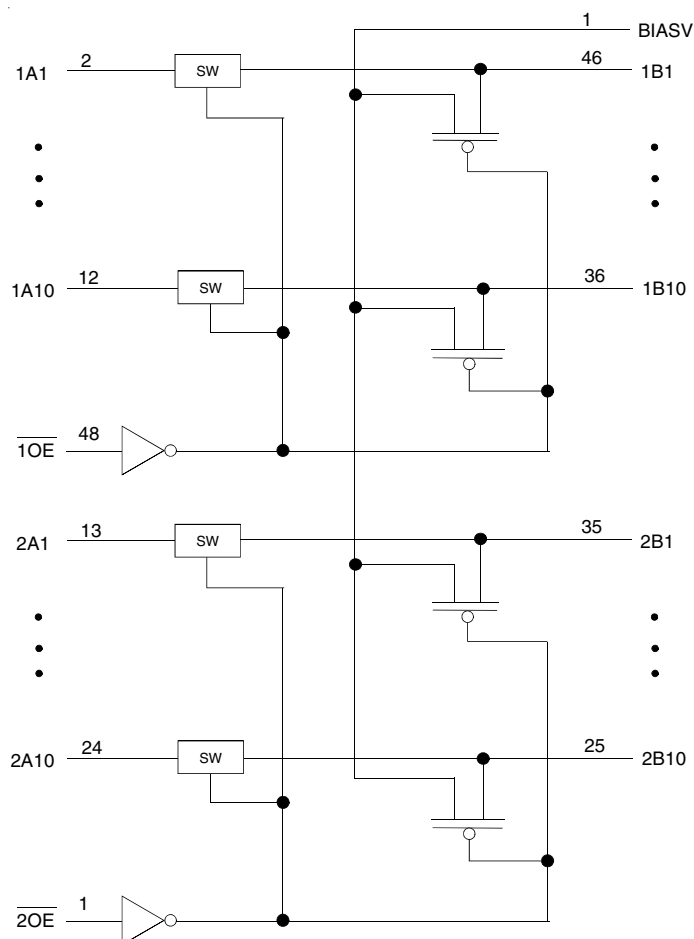

## DESCRIPTION:

The CBTLV16800 provides 20-bits of high-speed bus switching with low on-state resistance of the switch allowing connections to be made with minimal propagation delay. The device also precharges the B port to a user-selectable bias voltage (BIASV) to minimize live-insertion noise.

The CBTLV16800 is organized as dual 10-bit bus switches with two different output-enable ( $\overline{OE}$ ) control inputs. When  $\overline{OE}$  is low, the corresponding 10-bit bus switch is on and port A is connected to port B. When  $\overline{OE}$  is high, the switch is open, and a high impedance state exists between the two ports, and port B is precharged to BIASV through the equivalent of a 10-kΩ resistor.

To ensure the high-impedance state during power up or power down,  $\overline{OE}$  should be tied to Vcc through a pullup resistor; the minimum value of the resistor is determined by the current-sinking capability of the driver.

### NOTES:

1. The increase in supply current is attributable to each input that is at the specified voltage level rather than  $V_{CC}$  or GND.
2. This is measured by the voltage drop between the A and B terminals at the indicated current through the switch. On-state resistance is determined by the lower of the voltages of the two (A or B) terminals.
