

Power Management Unit for Advanced Application Processors

Check for Samples: [LP3972](#)

FEATURES

- Compatible With Advanced Applications Processors Requiring DVM (Dynamic Voltage Management)
- Three Buck Regulators for Powering High-Current Processor Functions or I/Os
- Six LDOs for Powering RTC, Peripherals, and I/Os
- Backup Battery Charger With Automatic Switch for Lithium-Manganese Coin Cell Batteries and Super Capacitors
- I²C Compatible High-Speed Serial Interface
- Software Control of Regulator Functions and Settings
- Precision Internal Reference
- Thermal Overload Protection
- Current Overload Protection
- Tiny 40-Pin 5x5 mm WQFN Package

KEY SPECIFICATIONS

- Buck Regulators
 - Programmable V_{OUT} from 0.725 to 3.3V
 - Up to 95% efficiency
 - Up to 1.6A output current
 - $\pm 3\%$ output voltage accuracy
- LDOs
 - Programmable V_{OUT} of 1.0V–3.3V
 - $\pm 3\%$ output voltage accuracy
 - 150/300/400 mA output currents
 - LDO_RTC 30 mA
 - LDO1 300 mA
 - LDO2 150 mA
 - LDO3 150 mA
 - LDO4 150 mA
 - LDO5 400 mA
 - 100 mV (typ) dropout

APPLICATIONS

- PDA Phones
- Smart Phones
- Personal Media Players
- Digital Cameras
- Application Processors
 - Marvell PXA
 - Freescale
 - Samsung

DESCRIPTION

The LP3972 is a multi-function programmable Power Management Unit designed especially for advanced application processors. The LP3972 is optimized for low-power handheld applications and provides six low-dropout low-noise linear regulators, three DC/DC magnetic buck regulators, a back-up battery charger, and two GPIOs. A high-speed serial interface is included to program individual regulator output voltages as well as on and off control.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

All trademarks are the property of their respective owners.

PRODUCTION DATA information is current as of publication date. Products conform to specifications per the terms of the Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

Application Circuits

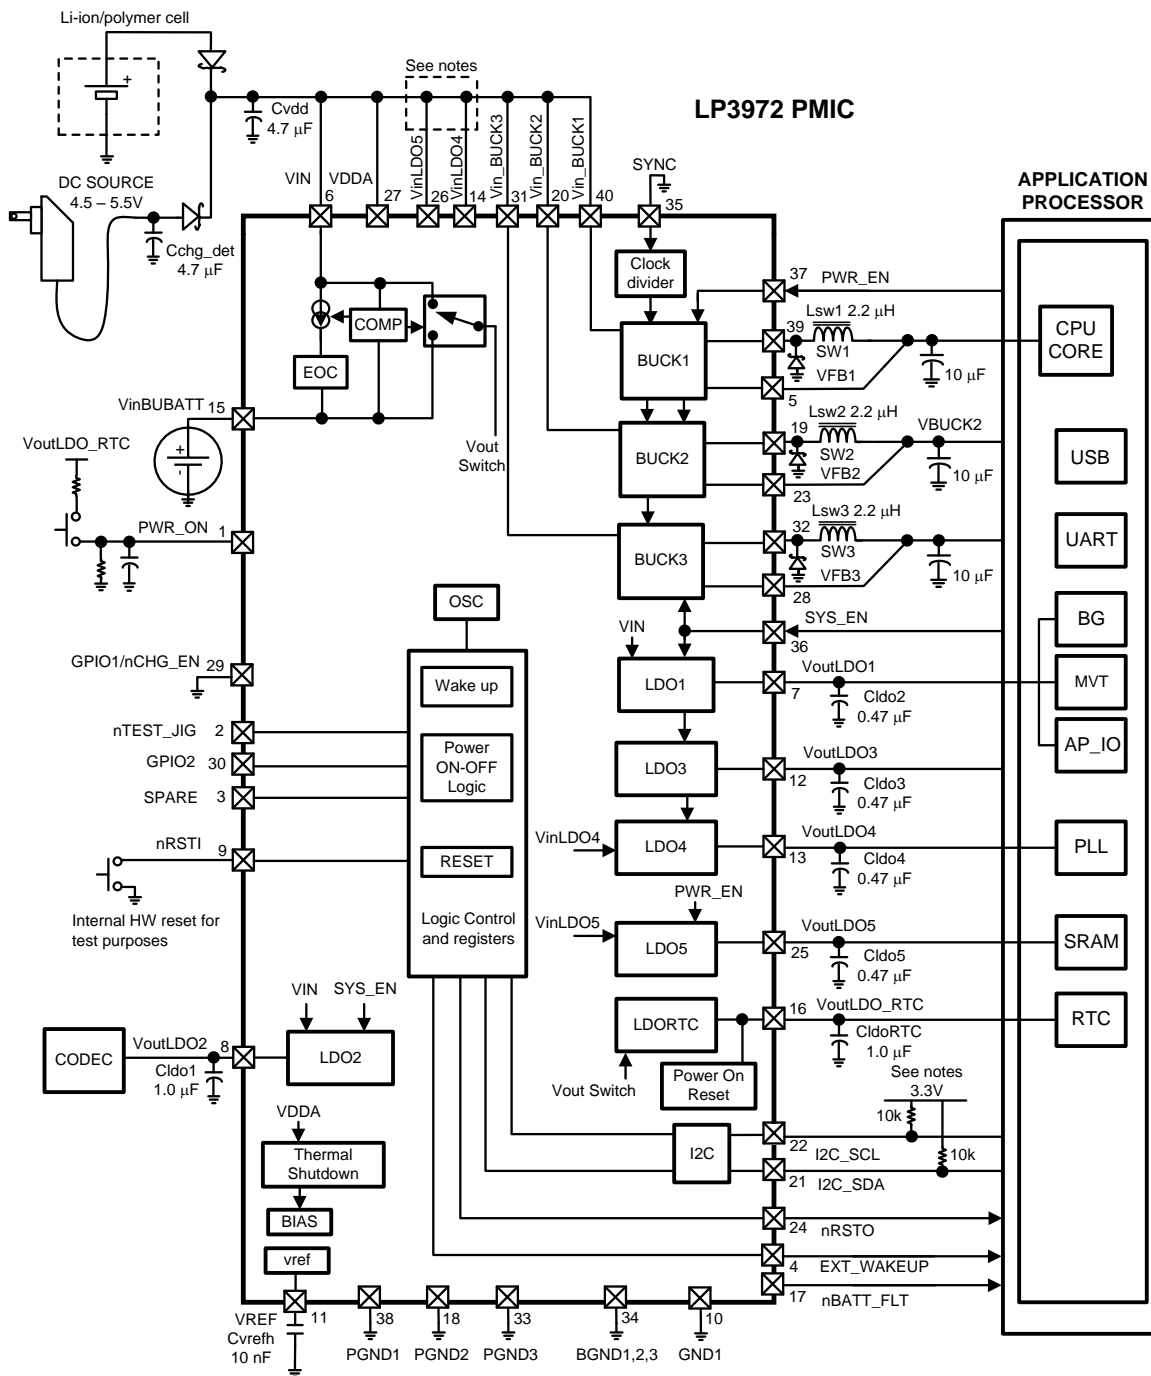

Figure 1. Simplified Application Circuit

- The I²C lines are pulled up via a I/O source
- V_{IN}LDOs 4, 5 can either be powered from main battery source, or by a buck regulator or V_{IN}.

Figure 2. Application Circuit

Connection Diagram

Note: Circle marks pin 1 position.

40-Pin WQFN, Package Number RSB0040A

PIN DESCRIPTIONS

Pin No.	Name	I/O	Type ⁽¹⁾	Description
1	PWR_ON	I	D	This is an active HI push button input which can be used to signal PWR_ON and PWR_OFF events to the CPU by controlling the ext_wakeup [pin4] and select contents of register 8H'88
2	nTEST_JIG	I	D	This is an active LOW input signal used for detecting an external HW event. The response is seen in the ext_wakeup [pin4] and select contents of register 8H'88
3	SPARE	I	D	This is an input signal used for detecting a external HW event. The response is seen in the ext_wakeup [pin4] and select contents of register 8H'88. The polarity on this pin is assignable
4	EXT_WAKEUP	O	D	This pin generates a single 10 ms pulse output to CPU in response to input from pins 1, 2, and 3. Flags CPU to interrogate register 8H'88
5	FB1	I	A	Buck1 input feedback terminal
6	V _{IN}	I	PWR	Battery Input (Internal circuitry and LDO1-3 power input)
7	V _{OUT} LDO1	O	PWR	LDO1 output
8	V _{OUT} LDO2	O	PWR	LDO2 output
9	nRSTI	I	D	Active low Reset pin. Signal used to reset the IC (by default is pulled high internally). Typically a push button reset.
10	GND1	G	G	Ground
11	VREF	O	A	Bypass Cap. for the high internal impedance reference.
12	V _{OUT} LDO3	O	PWR	LDO3 output
13	V _{OUT} LDO4	O	PWR	LDO4 output
14	V _{IN} LDO4	I	PWR	Power input to LDO4, this can be connected to either from a 1.8V supply to main Battery supply.
15	V _{IN} BUBATT	I	PWR	Back Up Battery input supply.
16	V _{OUT} LDO_RTC	O	PWR	LDO_RTC output supply to the RTC of the application processor.
17	nBATT_FLT	O	D	Main Battery fault output, indicates the main battery is low (discharged) or the dc source has been removed from the system. This gives the processor an indicator that the power will shut down. During this time the processor will operate from the back up coin cell.
18	PGND2	G	G	Buck2 NMOS Power Ground
19	SW2	O	PWR	Buck2 switcher output

(1) A: Analog Pin D: Digital Pin G: Ground Pin P: Power Pin I: Input Pin I/O: Input/Output Pin O: Output Pin

Note: In this document, active-low logic items are prefixed with a lowercase "n".

PIN DESCRIPTIONS (continued)

Pin No.	Name	I/O	Type ⁽¹⁾	Description
20	V _{IN} Buck2	I	PWR	Battery input power to Buck2
21	SDA	I/O	D	I ² C Data (Bidirectional)
22	SCL	I	D	I ² C Clock
23	FB2	I	A	Buck2 input feedback terminal
24	nRSTO	O	D	Reset output from the PMIC to the processor
25	V _{OUT} LDO5	O	PWR	LDO5 output
26	V _{IN} LDO5	I	PWR	Power input to LDO5, this can be connected to V _{IN} or to a separate 1.8V supply.
27	VDDA	I	PWR	Analog Power for VREF, BIAS
28	FB3	I	A	Buck3 Feedback
29	GPIO1 / nCHG_EN	I/O	D	General Purpose I/O / Ext. backup battery charger enable pin. This pin enables the main battery / DC source power to charge the backup battery. This pin toggled via the application processor. By grounding this pin the DC source continuously charges the backup battery
30	GPIO2	I/O	D	General Purpose I/O
31	V _{IN} Buck3	I	PWR	Battery input power to Buck3
32	SW3	O	PWR	Buck3 switcher output
33	PGND3	G	G	Buck3 NMOS Power Ground
34	BGND1,2,3	G	G	Bucks 1, 2 and 3 analog Ground
35	SYNC	I	D	Frequency Synchronization: Connection to an external clock signal PLL to synchronize the PMIC internal oscillator.
36	SYS_EN	I	D	Input Digital enable pin for the high voltage power domain supplies. Output from the Monahans processor.
37	PWR_EN	I	D	Digital enable pin for the Low Voltage domain supplies. Output signal from the Monahans processor
38	PGND1	G	G	Buck1 NMOS Power Ground
39	SW1	O	PWR	Buck1 Switcher output
40	VIN Buck1	I	PWR	Battery input power to Buck1

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

Absolute Maximum Ratings⁽¹⁾⁽²⁾

All Inputs	-0.3V to +6.5V	
GND to GND SLUG	±0.3V	
Junction Temperature (T _{J-MAX})	150°C	
Storage Temperature	-65°C to +150°C	
Power Dissipation (T _A = 70°C) ⁽³⁾	3.2W	
Junction-to-Ambient Thermal Resistance θ_{JA} ⁽³⁾	25°C/W	
Maximum Lead Temp (Soldering)	260°C	
ESD Rating ⁽⁴⁾	Human Body Model	2 kV
	Machine Model	200V

- (1) Absolute Maximum Ratings are limits beyond which damage to the device may occur. Operating Ratings are conditions under which operation of the device is specified. Operating Ratings do not imply ensured performance limits. For specified performance limits and associated test conditions, see the Electrical Characteristics tables.
- (2) If Military/Aerospace specified devices are required, please contact the TI Sales Office/Distributors for availability and specifications.
- (3) In applications where high power dissipation and/or poor package thermal resistance is present, the maximum ambient temperature may have to be derated. Maximum ambient temperature (TA-MAX) is dependent on the maximum operating junction temperature (TJ-MAX-OP = 125°C), the maximum power dissipation of the device in the application (PD-MAX), and the junction-to ambient thermal resistance of the part/package in the application (θ_{JA}), as given by the following equation: TA-MAX = TJ-MAX-OP – (θ_{JA} x PD-MAX).
- (4) The Human body model is a 100 pF capacitor discharged through a 1.5 k Ω resistor into each pin. (MIL-STD-883 3015.7) The machine model is a 200 pF capacitor discharged directly into each pin. (EAIJ).

Operating Ratings

V_{IN}	2.7V to 5.5V
$V_{INLDO4, 5}$	1.74 to V_{IN}
Junction Temperature (T_J)	-40°C to +125°C
Operating Temperature (T_A)	-40°C to +85°C
Maximum Power Dissipation ($T_A = 70^\circ\text{C}$) ⁽¹⁾⁽²⁾	2.2W

- (1) In applications where high power dissipation and/or poor package thermal resistance is present, the maximum ambient temperature may have to be derated. Maximum ambient temperature (T_{A-MAX}) is dependent on the maximum operating junction temperature ($T_{J-MAX-OP} = 125^\circ\text{C}$), the maximum power dissipation of the device in the application (P_{D-MAX}), and the junction-to ambient thermal resistance of the part/package in the application (θ_{JA}), as given by the following equation: $T_{A-MAX} = T_{J-MAX-OP} - (\theta_{JA} \times P_{D-MAX})$.
- (2) Junction-to-ambient thermal resistance (θ_{JA}) is taken from a thermal modeling result, performed under the conditions and guidelines set forth in the JEDEC standard JESD51-7. The test board is a 4-layer FR-4 board measuring 102 mm x 76 mm x 1.6 mm with a 2x1 array of thermal vias. The ground plane on the board is 50 mm x 50 mm. Thickness of copper layers are 36 μm /1.8 μm /18 μm /36 μm (1.5 oz/1 oz/1 oz/1.5 oz). Ambient temperature in simulation is 22°C, still air. Power dissipation is 1W. Junction-to-ambient thermal resistance is highly application and board-layout dependent. In applications where high maximum power dissipation exists, special care must be paid to thermal dissipation issues in board design. The value of θ_{JA} of this product can vary significantly, depending on PCB material, layout, and environmental conditions. In applications where high maximum power dissipation exists (high V_{IN} , high I_{OUT}), special care must be paid to thermal dissipation issues. For more information on these topics, see Application Note AN-1187 *Leadless Leadframe Package (LLP)*([SNOA401](#)) and the Power Efficiency and Power Dissipation sections of this datasheet.

General Electrical Characteristics

Typical values and limits appearing in normal type apply for $T_J = 25^\circ\text{C}$. Limits appearing in **boldface** type apply over the entire junction temperature range for operation, -40°C to +125°C⁽¹⁾⁽²⁾⁽³⁾

Symbol	Parameter	Test Conditions	Min	Typ	Max	Unit
V_{IN} , VDDA, V_{IN} Buck1, 2 and 3	Battery Voltage		2.7	3.6	5.5	V
V_{INLDO4} , V_{INLDO5}	Power Supply for LDO 4 and 5		1.74	3.6	V_{IN}	V
T_{SD}	Thermal Shutdown ⁽⁴⁾	Temperature		160		°C
		Hysteresis		20		

- (1) All voltages are with respect to the potential at the GND pin.
- (2) All limits specified at room temperature (standard typeface) and at temperature extremes (bold typeface). All room temperature limits are production tested, ensured through statistical analysis or ensured by design. All limits at temperature extremes are ensured via correlation using standard Statistical Quality Control (SQC) methods. All limits are used to calculate Average Outgoing Quality Level (AOQL).
- (3) No input supply should be higher than VDDA
- (4) This electrical specification is ensured by design.

Supply Specifications⁽¹⁾⁽²⁾

Supply	V_{OUT} (Volts)		I_{MAX} : Maximum Current
	Range	Resolution	
	(V)	(mV)	Current (mA)
LDO_RTC	2.8V	N/A	30 mA dc source 10 mA backup source
LDO1 (V_{CC-MVT})	1.7 to 2.0	25	300
LDO2	1.8 to 3.3	100	150
LDO3	1.8 to 3.3	100	150
LDO4	1.0 to 3.3	50-600	150
LDO5 ($V_{CC-SRAM}$)	0.850 to 1.5	25	400
BUCK1 ($V_{CC-APPS}$)	0.725 to 1.5	25	1600
BUCK2	0.8 to 3.3	50-600	1600
BUCK3	0.8 to 3.3	50-600	1600

- (1) All voltages are with respect to the potential at the GND pin.
- (2) The Human body model is a 100 pF capacitor discharged through a 1.5 k Ω resistor into each pin. (MIL-STD-883 3015.7) The machine model is a 200 pF capacitor discharged directly into each pin. (EAIJ).

- (1) All voltages are with respect to the potential at the GND pin.
- (2) All limits specified at room temperature (standard typeface) and at temperature extremes (bold typeface). All room temperature limits are production tested, ensured through statistical analysis or ensured by design. All limits at temperature extremes are ensured via correlation using standard Statistical Quality Control (SQC) methods. All limits are used to calculate Average Outgoing Quality Level (AOQL).
- (3) Dropout voltage is the input-to-output voltage difference at which the output voltage is 100 mV below its nominal value.
- (4) LDO_RTC voltage can track LDO3 voltage. LP3972 has a tracking function (nIO_TRACK). When enabled, LDO_RTC voltage will track LDO3 voltage within 200mV down to 2.8V when LDO3 is enabled
- (5) V_{IN} minimum for line regulation values is 2.7V for LDOs 1–3 and 1.8V for LDOs 4 and 5. Condition does not apply to input voltages below the minimum input operating voltage.

LDOs 1 to 5

Unless otherwise noted, $V_{IN} = 3.6V$, $C_{IN} = 1.0 \mu F$, $C_{OUT} = 0.47 \mu F$, $C_{OUT} (V_{RTC}) = 1.0 \mu F$ ceramic. Typical values and limits appearing in normal type apply for $T_J = 25^\circ C$. Limits appearing in **boldface** type apply over the entire junction temperature range for operation, $-40^\circ C$ to $+125^\circ C$ ⁽¹⁾⁽²⁾⁽³⁾⁽⁴⁾⁽⁵⁾⁽⁶⁾⁽⁷⁾

Symbol	Parameter	Test Conditions	Min	Typ	Max	Unit
V_{OUT} Accuracy	Output Voltage Accuracy (Default V_{OUT})	Load Current = 1 mA	-3		3	%
ΔV_{OUT}	Line Regulation	$V_{IN} = 3.1V$ to $5.0V$ ⁽⁵⁾ , Load Current = 1 mA			0.15	%/V
	Load Regulation	$V_{IN} = 3.6V$, Load Current = 1 mA to I_{MAX}			0.011	%/mA
I_{SC}	Short Circuit Current Limit	LDO1–4, $V_{OUT} = 0V$		400		mA
		LDO5, $V_{OUT} = 0V$		500

PSRR	Power Supply Ripple Rejection	$f = 10$ kHz, Load Current = I_{MAX}		45		dB
I_Q	Quiescent Current "On"	$I_{OUT} = 0$ mA		40		μA
	Quiescent Current "On"	$I_{OUT} = I_{MAX}$		60		
	Quiescent Current "Off"	EN is de-asserted		0.03		
T_{ON}	Turn On Time	Start up from Shut-down		300		μsec
C_{OUT}	Output Capacitor	Capacitance for Stability $0^\circ C \leq T_J \leq 125^\circ C$	0.33	0.47		μF
		$-40^\circ C \leq T_J \leq 125^\circ C$	0.68	1.0		
		ESR	5		500	m Ω

- (1) All voltages are with respect to the potential at the GND pin.
- (2) All limits specified at room temperature (standard typeface) and at temperature extremes (bold typeface). All room temperature limits are production tested, ensured through statistical analysis or ensured by design. All limits at temperature extremes are ensured via correlation using standard Statistical Quality Control (SQC) methods. All limits are used to calculate Average Outgoing Quality Level (AOQL).
- (3) Dropout voltage is the input-to-output voltage difference at which the output voltage is 100 mV below its nominal value.
- (4) LDO_RTC voltage can track LDO3 voltage. LP3972 has a tracking function (nIQ_TRACK). When enabled, LDO_RTC voltage will track LDO3 voltage within 200mV down to 2.8V when LDO3 is enabled
- (5) V_{IN} minimum for line regulation values is 2.7V for LDOs 1–3 and 1.8V for LDOs 4 and 5. Condition does not apply to input voltages below the minimum input operating voltage.
- (6) An increase in the load current results in a slight decrease in the output voltage and vice versa.
- (7) Dropout voltage is the input-to-output voltage difference at which the output voltage is 100 mV below its nominal value. This specification does not apply for input voltages below 2.7V for LDOs 1–3 and 1.8V for LDOs 4 and 5.

I_Q	Quiescent Current	$I_{OUT} < 50 \mu A$		25		μA
C_{OUT}	Output Capacitance	$0 \mu A \leq I_{OUT} \leq 100 \mu A$		0.1		μF
	Output Capacitor ESR		5		500	m Ω

(1) All voltages are with respect to the potential at the GND pin.

(2) All limits specified at room temperature (standard typeface) and at temperature extremes (bold typeface). All room temperature limits are production tested, ensured through statistical analysis or ensured by design. All limits at temperature extremes are ensured via correlation using standard Statistical Quality Control (SQC) methods. All limits are used to calculate Average Outgoing Quality Level (AOQL).

(3) Back-up battery charge current is programmable via the I²C compatible interface. Refer to the Application Section for more information.

LP3972 Battery Switch Operation

The LP3972 has provisions for two battery connections, the main battery V_{BAT} and Backup Battery.

The function of the battery switch is to connect power to the LDO_RTC from the appropriate battery, depending on conditions described below:

- If only the backup battery is applied, the switch will automatically connect the LDO_RTC power to this battery.
- If only the main battery is applied, the switch will automatically connect the LDO_RTC power to this battery
- If both batteries are applied, and the main battery is sufficiently charged ($V_{BAT} > 3.1V$), the switch will automatically connect the LDO_RTC power to the main battery.
- As the main battery is discharged a separate circuit called nBATT_FLT will warn the system. Then if no action is taken to restore the charge on the main battery, and discharging is continued the battery switch will disconnect the input of the LDO_RTC from the main battery and connect to the backup battery.
- The main battery voltage at which the LDO_RTC is switched over from main to backup battery is 2.8V typically.
- There is a hysteric voltage in this switch operation, thus the LDO_RTC will not be reconnected to main battery until main battery voltage is greater than 3.1V typically.
- The system designer may wish to disable the battery switch when only a main battery is used. This is accomplished by setting the "no back up battery bit" in the control register 8h'0B bit 7 NBUB. With this bit set to "1", the above described switching will not occur, that is the LDO_RTC will remain connected to the main battery even as it is discharged below the 2.9V threshold. The Backup battery input should also be connected to main battery.

Logic Inputs and Outputs DC Operating Conditions⁽¹⁾

Logic Inputs (SYS_EN, PWR_EN, SYNC, nRSTI, PWR_ON, nTEST_JIG, SPARE and GPI's)

- (1) All voltages are with respect to the potential at the GND pin.
- (2) All limits specified at room temperature (standard typeface) and at temperature extremes (bold typeface). All room temperature limits are production tested, ensured through statistical analysis or ensured by design. All limits at temperature extremes are ensured via correlation using standard Statistical Quality Control (SQC) methods. All limits are used to calculate Average Outgoing Quality Level (AOQL).
- (3) The I²C signals behave like open-drain outputs and require an external pull-up resistor on the system module in the 2 kΩ to 20 kΩ range.
- (4) This electrical specification is ensured by design.

Detailed Description

Buck Converter Operation

DEVICE INFORMATION

The LP3972 includes three high efficiency step down DC-DC switching buck converters. Using a voltage mode architecture with synchronous rectification, the buck converters have the ability to deliver up to 1600 mA depending on the input voltage, output voltage, ambient temperature and the inductor chosen.

There are three modes of operation depending on the current required - PWM, PFM, and shutdown. The device operates in PWM mode at load currents of approximately 100 mA or higher, having voltage tolerance of $\pm 3\%$ with 95% efficiency or better. Lighter load currents cause the device to automatically switch into PFM for reduced current consumption. Shutdown mode turns off the device, offering the lowest current consumption ($I_{Q, \text{SHUTDOWN}} = 0.01 \mu\text{A typ}$).

Additional features include soft-start, under voltage protection, current overload protection, and thermal shutdown protection.

The part uses an internal reference voltage of 0.5V. It is recommended to keep the part in shutdown until the input voltage is 2.7V or higher.

CIRCUIT OPERATION

The buck converter operates as follows. During the first portion of each switching cycle, the control block turns on the internal PFET switch. This allows current to flow from the input through the inductor to the output filter capacitor and load. The inductor limits the current to a ramp with a slope of $(V_{\text{IN}} - V_{\text{OUT}})/L$, by storing energy in a magnetic field.

During the second portion of each cycle, the controller turns the PFET switch off, blocking current flow from the input, and then turns the NFET synchronous rectifier on. The inductor draws current from ground through the NFET to the output filter capacitor and load, which ramps the inductor current down with a slope of $-V_{\text{OUT}}/L$.

The output filter stores charge when the inductor current is high, and releases it when inductor current is low, smoothing the voltage across the load.

The output voltage is regulated by modulating the PFET switch on time to control the average current sent to the load. The effect is identical to sending a duty-cycle modulated rectangular wave formed by the switch and synchronous rectifier at the SW pin to a low-pass filter formed by the inductor and output filter capacitor. The output voltage is equal to the average voltage at the SW pin.

PWM OPERATION

During PWM operation the converter operates as a voltage mode controller with input voltage feed forward. This allows the converter to achieve good load and line regulation. The DC gain of the power stage is proportional to the input voltage. To eliminate this dependence, feed forward inversely proportional to the input voltage is introduced.

While in PWM (Pulse Width Modulation) mode, the output voltage is regulated by switching at a constant frequency and then modulating the energy per cycle to control power to the load. At the beginning of each clock cycle the PFET switch is turned on and the inductor current ramps up until the comparator trips and the control logic turns off the switch. The current limit comparator can also turn off the switch in case the current limit of the PFET is exceeded. Then the NFET switch is turned on and the inductor current ramps down. The next cycle is initiated by the clock turning off the NFET and turning on the PFET.

Figure 15. Typical PWM Operation

Internal Synchronous Rectification

While in PWM mode, the converters uses an internal NFET as a synchronous rectifier to reduce rectifier forward voltage drop and associated power loss. Synchronous rectification provides a significant improvement in efficiency whenever the output voltage is relatively low compared to the voltage drop across an ordinary rectifier diode.

Current Limiting

A current limit feature allows the converters to protect itself and external components during overload conditions. PWM mode implements current limiting using an internal comparator that trips at 2.0 A (typ). If the output is shorted to ground the device enters a timed current limit mode where the NFET is turned on for a longer duration until the inductor current falls below a low threshold, ensuring inductor current has more time to decay, thereby preventing runaway.

PFM OPERATION

At very light loads, the converter enters PFM mode and operates with reduced switching frequency and supply current to maintain high efficiency.

The part will automatically transition into PFM mode when either of two conditions occurs for a duration of 32 or more clock cycles:

1. The inductor current becomes discontinuous.
2. The peak PMOS switch current drops below the I_{MODE} level, (Typically $I_{MODE} < 30 \text{ mA} + V_{IN}/42\Omega$).

Figure 16. Typical PFM Operation

During PFM operation, the converter positions the output voltage slightly higher than the nominal output voltage during PWM operation, allowing additional headroom for voltage drop during a load transient from light to heavy load. The PFM comparators sense the output voltage via the feedback pin and control the switching of the output FETs such that the output voltage ramps between $<0.6\%$ and $<1.7\%$ above the nominal PWM output voltage. If the output voltage is below the "high" PFM comparator threshold, the PMOS power switch is turned on. It remains on until the output voltage reaches the 'high' PFM threshold or the peak current exceeds the IPFM level set for PFM mode. The typical peak current in PFM mode is: $IPFM = 112\text{ mA} + V_{IN}/27\Omega$. Once the PMOS power switch is turned off, the NMOS power switch is turned on until the inductor current ramps to zero. When the NMOS zero-current condition is detected, the NMOS power switch is turned off. If the output voltage is below the 'high' PFM comparator threshold (see Figure 17), the PMOS switch is again turned on and the cycle is repeated until the output reaches the desired level. Once the output reaches the 'high' PFM threshold, the NMOS switch is turned on briefly to ramp the inductor current to zero and then both output switches are turned off and the part enters an extremely low power mode. Quiescent supply current during this 'sleep' mode is $21\text{ }\mu\text{A}$ (typ), which allows the part to achieve high efficiencies under extremely light load conditions. When the output drops below the 'low' PFM threshold, the cycle repeats to restore the output voltage (average voltage in PFM mode) to $<1.15\%$ above the nominal PWM output voltage. If the load current should increase during PFM mode (see Figure 17) causing the output voltage to fall below the 'low2' PFM threshold, the part will automatically transition into fixed-frequency PWM mode. Typically when $V_{IN} = 3.6\text{V}$ the part transitions from PWM to PFM mode at 100 mA output current.

Figure 17. Operation in PFM Mode and Transfer to PWM Mode

SHUTDOWN MODE

During shutdown the PFET switch, reference, control and bias circuitry of the converters are turned off. The NFET switch will be open in shutdown to discharge the output. When the converter is enabled, EN, soft start is activated. It is recommended to disable the converter during the system power up and undervoltage conditions when the supply is less than 2.7V .

SOFT START

The buck converter has a soft-start circuit that limits in-rush current during start-up. During start-up the switch current limit is increased in steps. Soft start is activated only if EN goes from logic low to logic high after V_{IN} reaches 2.7V . Soft start is implemented by increasing switch current limit in steps of 213 mA , 425 mA , 850 mA and 1700 mA (typ. Switch current limit). The start-up time thereby depends on the output capacitor and load current demanded at start-up. Typical start-up times with $10\text{ }\mu\text{F}$ output capacitor and 1000 mA load current is $390\text{ }\mu\text{s}$ and with 1 mA load current it is $295\text{ }\mu\text{s}$.

LDO - LOW DROP OUT OPERATION

The LP3972 can operate at 100% duty cycle (no switching; PMOS switch completely on) for low drop out support of the output voltage. In this way the output voltage will be controlled down to the lowest possible input voltage. When the device operates near 100% duty cycle, output voltage ripple is approximately 25 mV. The minimum input voltage needed to support the output voltage is

$$V_{IN, MIN} = I_{LOAD} * (R_{DS(on), PFET} + R_{INDUCTOR}) + V_{OUT}$$

where

- I_{LOAD} = Load Current
- $R_{DS(on), PFET}$ = Drain to source resistance of PFET switch in the triode region
- $R_{INDUCTOR}$ = Inductor resistance

(1)

SPREAD SPECTRUM FEATURE

Periodic switching in the buck regulator is inherently a noisier function block compared to an LDO. It can be challenging in some critical applications to comply with stringent regulatory standards or simply to minimize interference to sensitive circuits in space limited portable systems. The regulator's switching frequency and harmonics can cause "noise" in the signal spectrum. The magnitude of this noise is measured by its power spectral density. The power spectral density of the switching frequency, F_C , is one parameter that system designers want to be as low as practical to reduce interference to the environment and subsystems within their products. The LP3972 has a user selectable function on chip, wherein a noise reduction technique known as "spread spectrum" can be employed to ease customer's design and production issues.

The principle behind spread spectrum is to modulate the switching frequency slightly and slowly, and spread the signal frequency over a broader bandwidth. Thus, its power spectral density becomes attenuated, and the associated interference electro-magnetic energy is reduced. The clock used to modulate the LP3972 buck regulator can be used as a spread spectrum clock via 2 I²C control register (System Control Register 1 (SCR1) 8h'80) bits bk_ssen , and $slomod$. With this feature enabled, the intense energy of the clock frequency can be spread across a small band of frequencies in the neighborhood of the center frequency. The results in a reduction of the peak energy!

The LP3972 spread spectrum clock uses a triangular modulation profile with equal rise and fall slopes. The modulation has the following characteristics:

- The center frequency: $F_C = 2$ MHz, and
- The modulating frequency, $f_M = 6.8$ kHz or 12 kHz.
- Peak frequency deviation: $\Delta_f = \pm 100$ kHz (or $\pm 5\%$)
- Modulation index $\beta = \Delta_f / f_M = 14.7$ or 8.3

Figure 18.

I²C Compatible Interface

I²C DATA VALIDITY

The data on SDA line must be stable during the HIGH period of the clock signal (SCL). In other words, state of the data line can only be changed when CLK is LOW.

Figure 19.

I²C START and STOP CONDITIONS

START and STOP bits classify the beginning and the end of the I²C session. START condition is defined as SDA signal transitioning from HIGH to LOW while SCL line is HIGH. STOP condition is defined as the SDA transitioning from LOW to HIGH while SCL is HIGH. The I²C master always generates START and STOP bits. The I²C bus is considered to be busy after START condition and free after STOP condition. During data transmission, I²C master can generate repeated START conditions. First START and repeated START conditions are equivalent, function-wise.

Figure 20.

TRANSFERRING DATA

Every byte put on the SDA line must be eight bits long, with the most significant bit (MSB) being transferred first. The number of bytes that can be transmitted per transfer is unrestricted. Each byte of data has to be followed by an acknowledge bit. The acknowledge related clock pulse is generated by the master. The transmitter releases the SDA line (HIGH) during the acknowledge clock pulse. The receiver must pull down the SDA line during the 9th clock pulse, signifying an acknowledge. A receiver which has been addressed must generate an acknowledge after each byte has been received.

After the START condition, a chip address is sent by the I²C master. This address is seven bits long followed by an eighth bit which is a data direction bit (R/W). The LP3972 address is 34h. For the eighth bit, a "0" indicates a WRITE and a "1" indicates a READ. The second byte selects the register to which the data will be written. The third byte contains data to write to the selected register.

I²C CHIP ADDRESS - 7h'34

MSB							
ADR6 Bit7	ADR5 Bit6	ADR4 Bit5	ADR3 Bit4	ADR2 Bit3	ADR1 Bit2	ADR0 Bit1	R/W Bit0
0	1	1	0	1	0	0	R/W

Write Cycle

Figure 21. Write cycle

Read Cycle

When a READ function is to be accomplished, a WRITE function must precede the READ function as follows.

w = write (SDA = "0")

r = read (SDA = "1")

ack = acknowledge (SDA pulled down by either master or slave)

rs = repeated start

id = 34h (Chip Address)

Figure 22. Read Cycle

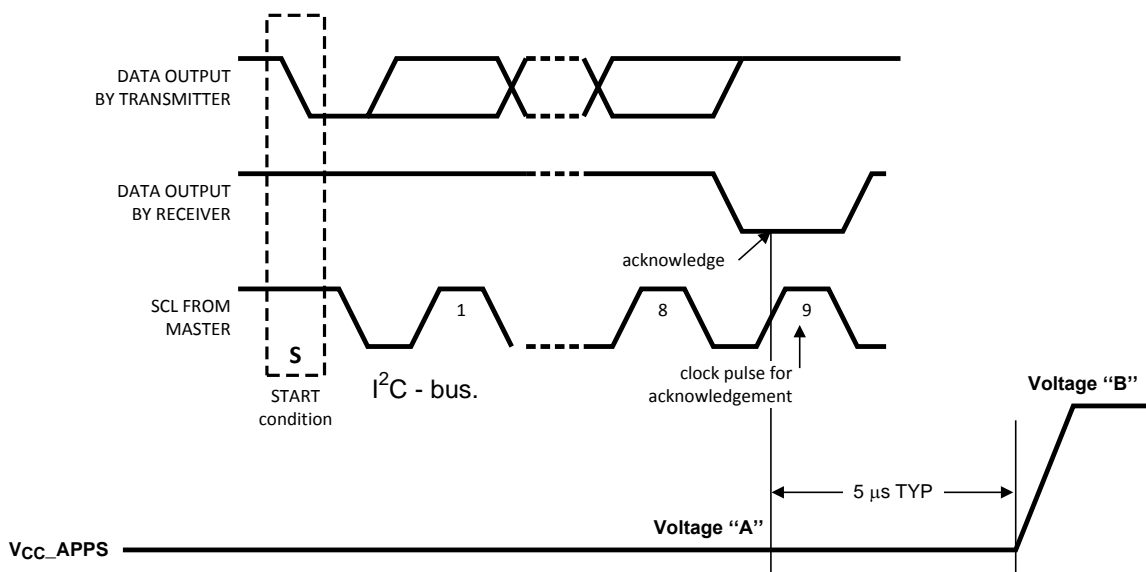

Figure 23. I²C DVM Timing for VCC_APPS (Buck1)

MULTI-BYTE I²C COMMAND SEQUENCE

To correctly function with the Monahan's Power Management I²C the LP3972's I²C serial interface shall support Random register Multi-byte command sequencing: During a multi-byte write the Master sends the Start command followed by the Device address, which is sent only once, followed by the 8 Bit register address, then 8 bits of data. The I²C slave must then accept the next random register address followed by 8 bits of data and continue this process until the master sends a valid stop condition.

A Typical Multi-byte random register transfer is outlined below:

Device Address,	Register A Address, Ach, Register A Data, Ach Register M Address, Ach, Register M Data, Ach Register X Address, Ach, Register X Data, Ach Register Z Address, Ach, Register Z Data, Ach, Stop
-----------------	--

Note: The PMIC is not required to see the I²C device address for each transaction. A, M, X, and Z are Random numbers.

Figure 24.

INCREMENTAL REGISTER I²C COMMAND SEQUENCE

The LP3972 supports address increment (burst mode). When you have defined register address n data bytes can be sent and register address is incremented after each data byte has been sent. Address incrimination may be required for non XScale applications. User can define whether multi-byte (default) to random address or address incrimination will be used.

POWER DOMAINS SEQUENCING (DELAY)

By default SYS_EN must be on to have PWR_EN enable but this feature can be switched off by register bit BP_SYS.

By default SYS_EN enables LDO1 always first and after a typical of 1 ms delay others. Also when SYS_EN is set off the LDO1 will go off last. This function can be switched off or delay can be changed by DELAY bits via serial interface as seen on table below.

8h'80 Bit 5:4

DELAY bits	'00'	'01'	'10'	'11'
Delay, ms	0	0.5	1.0	1.5

LDO_RTC TRACKING (nIO_TRACK)

LP3972 has a tracking function (nIO_TRACK). When enabled, LDO_RTC voltage will track LDO3 voltage within 200 mV down to 2.8V when LDO3 is enabled. This function can be switched on/off by nIO_TRACK register bit BPTR.

POWER SUPPLY ENABLE

SYS_EN and PWR_EN can be changed by programmable register bits.

WAKE-UP FUNCTIONALITY (PWR_ON, nTEST_JIG, SPARE AND EXT_WAKEUP)

Three input pins can be used to assert wakeup output for 10 ms for application processor notification to wakeup. SPARE Input can be programmed through I²C compatible interface to be active low or high (SPARE bit, Default is active low '1'). A reason for wakeup event can be read through I²C compatible interface also. Additionally wakeup inputs have 30 ms de-bounce filtering. Furthermore PWR_ON have distinguishing between short and long (~1s) pulses (push button input). LP3972 also has an internal Thermal Shutdown early warning that generates a wakeup to the system also. This is generated usually at 125°C.

Figure 28.

WAKEUP register bits	Reason for WAKEUP
WUP0	SPARE
WUP1	TEST_JIG
WUP2	PWR_ON short pulse
WUP3	PWR_ON long pulse
TSD_EW	TSD Early Warning

INTERNAL THERMAL SHUTDOWN PROCEDURE

Thermal shutdown is build to generate early warning (typ. 125°C) which triggers the EXT_WAKEUP for the processor acknowledge. When a thermal shutdown triggers (typ. 160°C) the PMU will reset the system until the device cools down.

BATTERY SWITCH AND BACK UP BATTERY CHARGER

When Back-Up battery is connected but the main battery has been removed or its supply voltage too low, LP3972 uses Back-Up Battery for generating LDO_RTC voltage. When Main Battery is available the battery FET switches over to the main battery for LDO_RTC voltage. When Main battery voltage is too low or removed nBATT_FLT is asserted. If no back up battery exists, the battery switch to back up can be switched off by nBU_BAT_EN bit. User can set the battery fault determination voltage and battery charger current via I²C compatible interface. Enabling of back up battery charger can be done via serial interface (nBAT_CHG_EN) or external charger enable pin (nCHG_EN). Pin 29 is set as external charger enable input by default.

GENERAL PURPOSE I/O FUNCTIONALITY (GPIO1 AND GPIO2)

LP3972 has 2 general purpose I/Os for system control. I²C compatible interface will be used for setting any of the pins to input, output or hi-Z mode. Inputs value can be read via serial interface (GPIO1,2 bits). The pin 29 functionality needs to be set to GPIO by serial interface register bit nEXTCHGEN. (GPIO/CHG)

1	1		1	Output = 1	0

The LP3972 has provision for two battery connections, the main battery V_{BAT} and Backup Battery (See Applications Schematic Diagrams 1 & 2 of the LP3972 Data Sheet).

The function of the battery switch is to connect power to the LDO_RTC from the appropriate battery, depending on conditions described below:

- If only the backup battery is applied, the switch will automatically connect the LDO_RTC power to this battery.
- If only the main battery is applied, the switch will automatically connect the LDO_RTC power to this battery.
- If both batteries are applied, and the main battery is sufficiently charged ($V_{BAT} > 3.1V$), the switch will automatically connect the RTC LDO power to the main battery.
- As the main battery is discharged by use, the user will be warned by a separate circuit called nBATT_FLT. Then if no action is taken to restore the charge on the main battery, and discharging is continued the battery switch will protect the LDO_RTC by disconnecting from the main battery and connecting to the backup battery.
 - The main battery voltage at which the LDO_RTC is switched from main to backup battery is 2.9V typically.
 - There is a hysteresis voltage in this switch operation so, the LDO_RTC will not be reconnected to main battery until main battery voltage is greater than 3.1V typically.
- Additionally, the user may wish to disable the battery switch, such as, in the case when only a main battery is used. This is accomplished by setting the "no back up battery bit" in the control register 8h'89 bit 7 NBUB. With this bit set to "1", the above described switching will not occur, that is the LDO_RTC will remain connected to the main battery even as it is discharged below the 2.9 Volt threshold.

REGULATED VOLTAGES OK

All the power domains have own register bit (X_OK) that processor can read via serial interface to be sure that enabled powers are OK (regulating). Note that these read only bits are only valid when regulators are settled (avoid reading these bits during voltage change or power up).

THERMAL MANAGEMENT

Application: There is a mode wherein all 6 comparators (flags) can be turned on via the "enallflags" control register bit. This mode allows the user to interrogate the device or system temperature under the set operating conditions. Thus, the rate of temperature change can also be estimated. The system may then negotiate for speed and power trade off, or deploy cooling maneuvers to optimize system performance. The "enallflags" bit needs enabled only when the "bct<2:0>" bits are read to conserve power.

Note: The thermal management flags have been verified functional. Presently these registers are accessible by factory only. If there is a demand for this function, the relevant register controls may be shifted into the user programmable bank; the temperature range and resolution of these flags, might also be refined/redefined.

THERMAL WARNING

2 of 6 low power comparators, each consumes less than 1 μA , are always enabled to operate the "T=125°C" warning flag with hysteresis. This allows continuous monitoring of a thermal-warning flag feature with very low power consumption.

LP3972 THERMAL FLAGS FUNCTIONAL DIAGRAM, DATA FROM INITIAL SILICON

The following functions are extra features from the thermal shutdown circuit:

1) Thermal warning flag @ Temp ~ > ~125°C is issued at the wakeup port:

2) Binary coded thermal management flags in status registers, bct<2:0>:

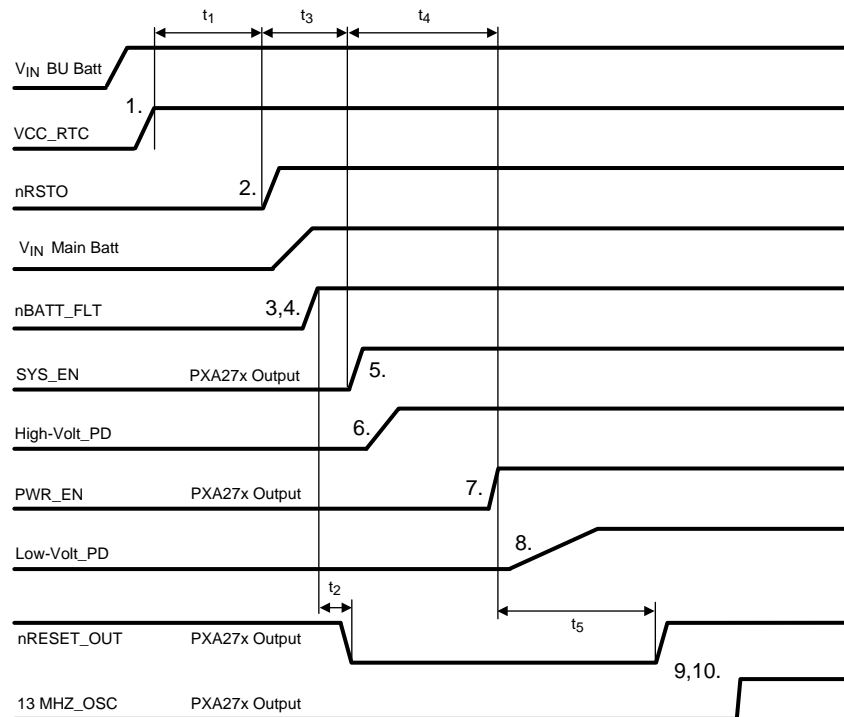

Figure 29.

Application Note - LP3972 Reset Sequence

INITIAL COLD START POWER ON SEQUENCE

1. The Back up battery is connected to the PMU, power is applied to the back-up battery pin, the LDO_RTC turns on and supplies a stable output voltage to the V_{CC_BATT} pin of the Applications processor (initiating the power-on reset event) with nRSTO asserted from the LP3972 to the processor.
2. nRSTO de-asserts after a minimum of 50 mS.
3. The Applications processor waits for the de-assertion of nBATT_FLT to indicate system power (V_{IN}) is available.
4. After system power (V_{IN}) is applied, the LP3972 de-asserts nBATT_FLT. Note that BOTH nRSTO and nBATT_FLT need to be de-asserted before SYS_EN is enabled. The sequence of the two signals is independent of each other.
5. The Applications processor asserts SYS_EN, the LP3972 enables the system high-voltage power supplies. The Applications processor starts its countdown timer set to 125 mS.
6. The LP3972 enables the high-voltage power supplies.
 - LDO1 power for V_{CC_MVT} (Power for internal logic and I/O Blocks), BG (Bandgap reference voltage), OSC13M (13 MHz oscillator voltage) and PLL enabled first, followed by others if delay is on.
7. Countdown timer expires; the Applications processor asserts PWR_EN to enable the low-voltage power supplies. The processor starts the countdown timer set to 125 mS period.
8. The Applications processor asserts PWR_EN (ext. pin or I²C), the LP3972 enables the low-voltage regulators.
9. Countdown timer expires; If enabled power domains are OK (I²C read) the power up sequence continues by enabling the processors 13 MHz oscillator and PLL's.
10. The Applications processor begins the execution of code.

* Note that BOTH nRSTO and nBATT_FLT need to be de-asserted before SYS_EN is enabled. The sequence of the two signals is independent of each other and can occur in either order.

Figure 30.

POWER-ON TIMING

Symbol	Description	Min	Typ	Max	Unit
t1	Delay from V _{CC_RTC} assertion to nRSTO de-assertion	50			mS
t2	Delay from nBATT_FLT de-assertion to nRSTI assertion		100		μS
t3	Delay from nRST de-assertion to SYS_EN assertion		10		mS
t4	Delay from SYS_EN assertion to PWR_EN assertion		125		mS
t5	Delay from PWR_EN assertion to nRSTO de-assertion		125		mS

HARDWARE RESET SEQUENCE

Hardware reset initiates when the nRSTI signal is asserted (low). Upon assertion of nRST the processor enters hardware reset state. The LP3972 holds the nRST low long enough (50 ms typ.) to allow the processor time to initiate the reset state.

RESET SEQUENCE

1. nRSTI is asserted.
2. nRSTO is asserted and will de-asserts after a minimum of 50 mS
3. The Applications processor waits for the de-assertion of nBATT_FLT to indicate system power (V_{IN}) is available.
4. After system power (V_{IN}) is turned on, the LP3972 de-asserts nBATT_FLT.
5. The Applications processor asserts SYS_EN, the LP3972 enables the system high-voltage power supplies. The Applications processor starts its countdown timer.
6. The LP3972 enables the high-voltage power supplies.
7. Countdown timer expires; the Applications processor asserts PWR_EN to enable the low-voltage power supplies. The processor starts the countdown timer.

8. The Applications processor asserts PWR_EN, the LP3972 enables the low-voltage regulators.
9. Countdown timer expires; If enabled power domains are OK (I²C read) the power up sequence continues by enabling the processors 13 MHz oscillator and PLL's.
10. The Applications processor begins the execution of code.

APPLICATION HINTS

LDO CONSIDERATIONS

External Capacitors

The LP3972's regulators require external capacitors for regulator stability. These are specifically designed for portable applications requiring minimum board space and smallest components. These capacitors must be correctly selected for good performance.

Input Capacitor

An input capacitor is required for stability. It is recommended that a 1.0 μF capacitor be connected between the LDO input pin and ground (this capacitance value may be increased without limit).

This capacitor must be located a distance of not more than 1 cm from the input pin and returned to a clean analogue ground. Any good quality ceramic, tantalum, or film capacitor may be used at the input.

Important: Tantalum capacitors can suffer catastrophic failures due to surge current when connected to a low impedance source of power (like a battery or a very large capacitor). If a tantalum capacitor is used at the input, it must be ensured by the manufacturer to have a surge current rating sufficient for the application.

There are no requirements for the ESR (Equivalent Series Resistance) on the input capacitor, but tolerance and temperature coefficient must be considered when selecting the capacitor to ensure the capacitance will remain approximately 1.0 μF over the entire operating temperature range.

Output Capacitor

The LDOs are designed specifically to work with very small ceramic output capacitors. A 1.0 μF ceramic capacitor (temperature types Z5U, Y5V or X7R) with ESR between 5 m Ω to 500 m Ω , are suitable in the application circuit.

For this device the output capacitor should be connected between the V_{OUT} pin and ground.

It is also possible to use tantalum or film capacitors at the device output, C_{OUT} (or V_{OUT}), but these are not as attractive for reasons of size and cost (see the section Capacitor Characteristics).

The output capacitor must meet the requirement for the minimum value of capacitance and also have an ESR value that is within the range 5 m Ω to 500 m Ω for stability.

No-Load Stability

The LDOs will remain stable and in regulation with no external load. This is an important consideration in some circuits, for example CMOS RAM keep-alive applications.

Capacitor Characteristics

The LDOs are designed to work with ceramic capacitors on the output to take advantage of the benefits they offer. For capacitance values in the range of 0.47 μF to 4.7 μF , ceramic capacitors are the smallest, least expensive and have the lowest ESR values, thus making them best for eliminating high frequency noise. The ESR of a typical 1.0 μF ceramic capacitor is in the range of 20 m Ω to 40 m Ω , which easily meets the ESR requirement for stability for the LDOs.

For both input and output capacitors, careful interpretation of the capacitor specification is required to ensure correct device operation. The capacitor value can change greatly, depending on the operating conditions and capacitor type. In particular, the output capacitor selection should take account of all the capacitor parameters, to ensure that the specification is met within the application. The capacitance can vary with DC bias conditions as well as temperature and frequency of operation. Capacitor values will also show some decrease over time due to aging. The capacitor parameters are also dependant on the particular case size, with smaller sizes giving poorer

performance figures in general. As an example, [Figure 31](#) shows a typical graph comparing different capacitor case sizes in a Capacitance vs. DC Bias plot. As shown in the graph, increasing the DC Bias condition can result in the capacitance value falling below the minimum value given in the recommended capacitor specifications table. Note that the graph shows the capacitance out of spec for the 0402 case size capacitor at higher bias voltages. It is therefore recommended that the capacitor manufacturers' specifications for the nominal value capacitor are consulted for all conditions, as some capacitor sizes (e.g. 0402) may not be suitable in the actual application.

Figure 31. Graph Showing a Typical Variation in Capacitance vs. DC Bias

The ceramic capacitor's capacitance can vary with temperature. The capacitor type X7R, which operates over a temperature range of -55°C to $+125^{\circ}\text{C}$, will only vary the capacitance to within $\pm 15\%$. The capacitor type X5R has a similar tolerance over a reduced temperature range of -55°C to $+85^{\circ}\text{C}$. Many large value ceramic capacitors, larger than $1\text{ }\mu\text{F}$ are manufactured with Z5U or Y5V temperature characteristics. Their capacitance can drop by more than 50% as the temperature varies from 25°C to 85°C . Therefore X7R is recommended over Z5U and Y5V in applications where the ambient temperature will change significantly above or below 25°C .

Tantalum capacitors are less desirable than ceramic for use as output capacitors because they are more expensive when comparing equivalent capacitance and voltage ratings in the $0.47\text{ }\mu\text{F}$ to $4.7\text{ }\mu\text{F}$ range.

Another important consideration is that tantalum capacitors have higher ESR values than equivalent size ceramics. This means that while it may be possible to find a tantalum capacitor with an ESR value within the stable range, it would have to be larger in capacitance (which means bigger and more costly) than a ceramic capacitor with the same ESR value. It should also be noted that the ESR of a typical tantalum will increase about 2:1 as the temperature goes from 25°C down to -40°C , so some guard band must be allowed.

BUCK CONSIDERATIONS

Inductor Selection

There are two main considerations when choosing an inductor; the inductor should not saturate, and the inductor current ripple is small enough to achieve the desired output voltage ripple. Different saturation current rating specs are followed by different manufacturers so attention must be given to details. Saturation current ratings are typically specified at 25°C so ratings at max ambient temperature of application should be requested from manufacturer.

There are two methods to choose the inductor saturation current rating.

Method 1

The saturation current is greater than the sum of the maximum load current and the worst case average to peak inductor current. This can be written as

$$I_{SAT} > I_{OUTMAX} + I_{RIPPLE}$$

$$\text{where } I_{RIPPLE} = \left(\frac{V_{IN} - V_{OUT}}{2 * L} \right) * \left(\frac{V_{OUT}}{V_{IN}} \right) * \left(\frac{1}{f} \right)$$

where

- I_{RIPPLE} : Average to peak inductor current
- I_{OUTMAX} : Maximum load current (1500 mA)
- V_{IN} : Maximum input voltage in application
- L : Min inductor value including worst case tolerances (30% drop can be considered for method 1)
- f : Minimum switching frequency (1.6 MHz)
- V_{OUT} : Output voltage

(2)

Method 2

A more conservative and recommended approach is to choose an inductor that has saturation current rating greater than the max current limit of 3A.

A 2.2 μ H inductor with a saturation current rating of at least 3A is recommended for most applications. The inductor's resistance should be less than 0.3 Ω for a good efficiency. Table 1 lists suggested inductors and suppliers. For low-cost applications, an unshielded bobbin inductor could be considered. For noise critical applications, a toroidal or shielded bobbin inductor should be used. A good practice is to lay out the board with overlapping footprints of both types for design flexibility. This allows substitution of a low-noise shielded inductor, in the event that noise from low-cost bobbin models is unacceptable.

Input Capacitor Selection

A ceramic input capacitor of 10 μ F, 6.3V is sufficient for most applications. Place the input capacitor as close as possible to the V_{IN} pin of the device. A larger value may be used for improved input voltage filtering. Use X7R or X5R types, do not use Y5V. DC bias characteristics of ceramic capacitors must be considered when selecting case sizes like 0805 and 0603. The input filter capacitor supplies current to the PFET switch of the converter in the first half of each cycle and reduces voltage ripple imposed on the input power source. A ceramic capacitor's low ESR provides the best noise filtering of the input voltage spikes due to this rapidly changing current. Select a capacitor with sufficient ripple current rating. The input current ripple can be calculated as:

$$I_{RMS} = I_{OUTMAX} * \sqrt{\frac{V_{OUT}}{V_{IN}} * \left(1 - \frac{V_{OUT}}{V_{IN}} + \frac{r^2}{12} \right)}$$

$$\text{where } r = \frac{(V_{IN} - V_{OUT}) * V_{OUT}}{L * f * I_{OUTMAX} * V_{IN}}$$

(3)

The worst case is when $V_{IN} = 2 * V_{OUT}$

Table 1. Suggested Inductors and Their Suppliers

Model	Vendor	Dimensions LxWxH (mm)	D.C.R. (Typ)
FDSE0312-2R2M	Toko	3.0 x 3.0 x 1.2	160 m Ω
DO1608C-222	Coilcraft	6.6 x 4.5 x 1.8	80 m Ω

Output Capacitor Selection

Use a 10 μ F, 6.3V ceramic capacitor. Use X7R or X5R types, do not use Y5V. DC bias characteristics of ceramic capacitors must be considered when selecting case sizes like 0805 and 0603. DC bias characteristics vary from manufacturer to manufacturer and dc bias curves should be requested from them as part of the capacitor selection process. The output filter capacitor smooths out current flow from the inductor to the load, helps maintain a steady output voltage during transient load changes and reduces output voltage ripple. These capacitors must be selected with sufficient capacitance and sufficiently low ESR to perform these functions.

The output voltage ripple is caused by the charging and discharging of the output capacitor and also due to its ESR and can be calculated as:

$$V_{PP-C} = \frac{I_{RIPPLE}}{4 * f * C} \quad (4)$$

Voltage peak-to-peak ripple due to ESR can be expressed as follows

$$V_{PP-ESR} = (2 * I_{RIPPLE}) * R_{ESR} \quad (5)$$

Because these two components are out of phase the RMS value can be used to get an approximate value of peak-to-peak ripple.

Voltage peak-to-peak ripple, root mean squared can be expressed as follows

$$V_{PP-RMS} = \sqrt{V_{PP-C}^2 + V_{PP-ESR}^2} \quad (6)$$

Note that the output voltage ripple is dependent on the inductor current ripple and the equivalent series resistance of the output capacitor (R_{ESR}).

The R_{ESR} is frequency dependent (as well as temperature dependent); make sure the value used for calculations is at the switching frequency of the part.

Table 2. Suggested Capacitor and Their Suppliers

Model	Type	Vendor	Voltage	Case Size Inch (mm)
GRM21BR60J106K	Ceramic, X5R	Murata	6.3V	0805 (2012)
JMK212BJ106K	Ceramic, X5R	Taiyo-Yuden	6.3V	0805 (2012)
C2012X5R0J106K	Ceramic, X5R	TDK	6.3V	0805 (2012)

Buck Output Ripple Management

If V_{IN} and I_{LOAD} increase, the output ripple associated with the Buck Regulators also increases. [Figure 32](#) shows the safe operating area. To ensure operation in the area of concern it is recommended that the system designer circumvents the output ripple issues to install Schottky diodes on the Buck(s) that are expected to perform under these extreme corner conditions.

(Schottky diodes are recommended to reduce the output ripple, if system requirements include this shaded area of operation. $V_{IN} > 1.5V$ and $I_{LOAD} > 1.24$)

Figure 32.

Board Layout Considerations

PC board layout is an important part of DC-DC converter design. Poor board layout can disrupt the performance of a DC-DC converter and surrounding circuitry by contributing to EMI, ground bounce, and resistive voltage loss in the traces. These can send erroneous signals to the DC-DC converter IC, resulting in poor regulation or instability.

Good layout for the converters can be implemented by following a few simple design rules.

1. Place the converters, inductor and filter capacitors close together and make the traces short. The traces between these components carry relatively high switching currents and act as antennas. Following this rule reduces radiated noise. Special care must be given to place the input filter capacitor very close to the V_{IN} and GND pin.
2. Arrange the components so that the switching current loops curl in the same direction. During the first half of each cycle, current flows from the input filter capacitor through the converter and inductor to the output filter capacitor and back through ground, forming a current loop. In the second half of each cycle, current is pulled up from ground through the converter by the inductor to the output filter capacitor and then back through ground forming a second current loop. Routing these loops so the current curls in the same direction prevents magnetic field reversal between the two half-cycles and reduces radiated noise.
3. Connect the ground pins of the converter and filter capacitors together using generous component-side copper fill as a pseudo-ground plane. Then, connect this to the ground-plane (if one is used) with several vias. This reduces ground-plane noise by preventing the switching currents from circulating through the ground plane. It also reduces ground bounce at the converter by giving it a low-impedance ground connection.
4. Use wide traces between the power components and for power connections to the DC-DC converter circuit. This reduces voltage errors caused by resistive losses across the traces.
5. Route noise sensitive traces, such as the voltage feedback path, away from noisy traces between the power components. The voltage feedback trace must remain close to the converter circuit and should be direct but should be routed opposite to noisy components. This reduces EMI radiated onto the DC-DC converter's own voltage feedback trace. A good approach is to route the feedback trace on another layer and to have a ground plane between the top layer and layer on which the feedback trace is routed. In the same manner for the adjustable part it is desired to have the feedback dividers on the bottom layer.
6. Place noise sensitive circuitry, such as radio RF blocks, away from the DC-DC converter, CMOS digital blocks and other noisy circuitry. Interference with noise-sensitive circuitry in the system can be reduced through distance.

REVISION HISTORY

Changes from Revision J (May 2013) to Revision K	Page
<ul style="list-style-type: none">Changed layout of National Data Sheet to TI format	48

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
