Figure 1 and Figure 2 represent the phase relationship among the different groups of clock outputs from W224 when it is providing a 66-MHz CPU clock and a 100-MHz CPU clock, re-

spectively. It should be noted that when CPU clock is operating at 100 MHz, CPU clock output is 180 degrees out of phase with SDRAM clock outputs.

Power Down Control

W224 provides one PWR_DWN# signal to place the device in low-power mode. In low-power mode, the PLLs are turned off and all clock outputs are driven LOW.

Notes:

8. Once the PWR_DWN# signal is sampled LOW for two consecutive rising edges of CPU, clocks of interest will be held LOW on the next HIGH-to-LOW transition.
9. PWR_DWN# is an asynchronous input and metastable conditions could exist. This signal is synchronized inside W224.
10. The shaded sections on the SDRAM, REF, and USB clocks indicate "don't care" states.

Spread Spectrum Frequency Timing Generation

The device generates a clock that is frequency modulated in order to increase the bandwidth that it occupies. By increasing the bandwidth of the fundamental and its harmonics, the amplitudes of the radiated electromagnetic emissions are reduced. This effect is depicted in *Figure 6*.

As shown in *Figure 6*, a harmonic of a modulated clock has a much lower amplitude than that of an unmodulated signal. The reduction in amplitude is dependent on the harmonic number and the frequency deviation or spread. The equation for the reduction is:

$$dB = 6.5 + 9 \cdot \log_{10}(P) + 9 \cdot \log_{10}(F)$$

Where *P* is the percentage of deviation and *F* is the frequency in MHz where the reduction is measured.

The output clock is modulated with a waveform depicted in *Figure 7*. This waveform, as discussed in “Spread Spectrum Clock Generation for the Reduction of Radiated Emissions” by Bush, Fessler, and Hardin produces the maximum reduction in the amplitude of radiated electromagnetic emissions. The deviation selected for this chip is -0.5% or -1.0% of the selected frequency. *Figure 7* details the Cypress spreading pattern. Cypress does offer options with more spread and greater EMI reduction. Contact your local Sales representative for details on these devices.

Spread Spectrum clocking is activated or deactivated by selecting the appropriate value for bit 3 in data byte 0 of the SMBus data stream. Refer to page 9 for more details.

Serial Data Interface

The W224 features a two-pin, serial data interface that can be used to configure internal register settings that control particular device functions.

Data Protocol

The clock driver serial protocol accepts only block writes from the controller. The bytes must be accessed in sequential order from lowest to highest byte with the ability to stop after any complete byte has been transferred. Indexed bytes are not allowed.

A block write begins with a slave address and a write condition. After the command code the core logic issues a byte count which describes how many more bytes will follow in the message. If the host had 20 bytes to send, the first byte would be

the number 20 (14h), followed by the 20 bytes of data. The byte count may not be 0. A block write command is allowed to transfer a maximum of 32 data bytes. The slave receiver address for W224 is 11010010. *Figure 8* shows an example of a block write.

The command code and the byte count bytes are required as the first two bytes of any transfer. W224 expects a command code of 0000 0000. The byte count byte is the number of additional bytes required for the transfer, not counting the command code and byte count bytes. Additionally, the byte count byte is required to be a minimum of 1 byte and a maximum of 32 bytes to satisfy the above requirement. *Table 8* shows an example of a possible byte count value.

A transfer is considered valid after the acknowledge bit corresponding to the byte count is read by the controller.

Table 8. Example of Possible Byte Count Value

Byte Count Byte		Notes
MSB	LSB	
0000	0000	Not allowed. Must have at least one byte
0000	0001	Data for functional and frequency select register (currently byte 0 in spec)
0000	0010	Writes first two bytes of data (byte 0 then byte 1)
0000	0011	Writes first three bytes (byte 0, 1, 2 in order)
0000	0100	Writes first four bytes (byte 0, 1, 2, 3 in order)
0000	0101	Writes first five bytes (byte 0, 1, 2, 3, 4 in order)
0000	0110	Writes first six bytes (byte 0, 1, 2, 3, 4, 5 in order)
0000	0111	Writes first seven bytes (byte 0, 1, 2, 3, 4, 5, 6 in order)
0010	0000	Max. byte count supported = 32

Note:

12. The acknowledgment bit is returned by the slave/receiver (W224).

W224 Serial Configuration Map

- The serial bits will be read by the clock driver in the following order:
 Byte 0 - Bits 7, 6, 5, 4, 3, 2, 1, 0
 Byte 1 - Bits 7, 6, 5, 4, 3, 2, 1, 0
 Byte N - Bits 7, 6, 5, 4, 3, 2, 1, 0
- All unused register bits (reserved and N/A) should be written to a "0" level.
- All register bits labeled "Initialize to 0" must be written to zero during initialization. Failure to do so may result in higher than normal operating current.

Byte 5 has been provided as an optional register to enable a greater degree of spread spectrum and overclocking performance for all PLL1 outputs. (CPU, SDRAM, DCLK, APIC, PCI, 3V66 and VCH_CLK)

By enabling Byte 5, (bits 5 and 6) spread spectrum can be increased to -1.0% and /or overclocking of either 5% or 10% can be enabled. Although the default values are '0' for all bits, the part can be placed into either Tri-State or Test Mode by

programming both bits 5 and 6 to '1'. The part will enter this mode irrespective of pin 33, TEST#.

It is not necessary to access Byte 5 if these additional features are not implemented. All outputs will default to 0% overclocking upon power up, with either 0% or -0.5% spread spectrum. (Spread spectrum ON/OFF remains under Byte 0, bit 3 control). Note that 10% overclocking can only be enabled with Spread Spectrum turned OFF.

Notes:

17. Period, jitter, offset, and skew measured on rising edge at 1.25 for 2.5V clocks and at 1.5V for 3.3V clocks.

 18. T_{HIGH} is measured at 2.0V for 2.5V outputs, 2.4V for 3.3V outputs.

 19. T_{LOW} is measured at 0.4V for all outputs.

 20. The time specified is measured from when V_{DDQ3} achieves its nominal operating level (typical condition $V_{DDQ3} = 3.3\text{V}$) until the frequency output is stable and operating within specification.

 21. T_{RISE} and T_{FALL} are measured as a transition through the threshold region $V_{ol} = 0.4\text{V}$ and $V_{oh} = 2.0\text{V}$ (1 mA) JEDEC specification for 2.5V outputs and $V_{ol} = 0.4\text{V}$ and $V_{oh} = 2.4\text{V}$ for 3.3V outputs.
